This is discussed further in Section 12.4 on page 253. The possibilities for specifying *font name* and *font features* are covered at length in Section 9.6 on page 705.

Here is a simple example setting up a typewriter italic font as a math alphabet:

```
\usepackage{unicode-math}
\setmathfontface\mathttit{texgyrecursor-italic.otf}

$$ttit \approx tt + italic$$

$$\mathttit{ttit} \approx \mathtt{tt} + \mathit{italic}$$

```

9-4-6

9.4.2 Text font commands in math

As mentioned previously, text font declarations like `\rmfamily` cannot be used in math. However, the font-changing commands with arguments—for example, `\textrm`—can be used in both text and math. You can use these commands to temporarily exit the math context and typeset some text in the midst of your formula that logically belongs to the text outside of the formula. Note that the font used to typeset this text therefore depends on surrounding conditions—that is, the command picks up the current values of encoding, family, series, and shape, and then changes one of the attributes as requested.

The result will be

```
\sffamily The result will be

$$x = 10 \textbf{ and thus } y = 12$$

$$[ x = 10 \texttt{ and thus } y = 12 ]$$

```

9-4-7

As you see, the Sans family was retained, and the series was changed to bold. Perhaps more useful is the `\text` command, provided by the `amsmath` package, which typesets in the current text font without any modification to it (see Section 11.6.1).

9.4.3 Mathematical formula versions

Besides allowing parts of a formula to be changed by using math alphabet identifiers, \LaTeX lets you change the appearance of a formula as a whole. Formulas are typeset in a certain “math version”, and you can switch between math versions outside of math mode by using the command `\mathversion`, thereby changing the overall layout of the following formulas.

\LaTeX knows about two math versions that are called “normal” and “bold”. Additional ones are sometimes provided in special packages. As the name indicates, `\mathversion{normal}` is the default. In contrast, the bold version produces bolder alphabet characters and symbols, though by default big operators, like `\sum`, are not changed. The following example shows the same formula first in the normal and then in the bold math version:

$\sum_{j=1}^z j = \frac{z(z+1)}{2} \quad (1)$	<pre>\begin{equation} \sum_{j=1}^z j = \frac{z(z+1)}{2} \end{equation}</pre>
$\sum_{j=1}^z j = \frac{z(z+1)}{2} \quad (2)$	<pre>\mathversion{bold} \begin{equation} \sum_{j=1}^z j = \frac{z(z+1)}{2} \end{equation}</pre>

9-4-8

For historical reasons L^AT_EX has two additional commands to switch to its standard math versions: `\boldmath` and `\unboldmath`.

Using `\mathversion` might be suitable in certain situations, such as in headings, but remember that changing the version means changing the appearance (and perhaps the meaning) of the entire formula. If you want to darken only some symbols or characters within one formula, you should not change the `\mathversion`. Instead, you should use the `\mathbf` alphabet identifier for characters and/or use the command `\bm` provided by the `bm` package; see Section 12.2.1.

If you change the math version with the `\mathversion` command, L^AT_EX looks in its internal tables to find where all the symbols for this new math version are located. It also may change all or some of the math alphabet identifiers and associate them with other font shapes in this version.

What happens to math alphabet identifiers that you have defined yourself, such as the `\mathsfsl` from Example 9-4-5? As long as you declared them using only `\DeclareMathAlphabet`, they stay the same in all math versions.

If the math alphabet identifier is to produce a different font in a special math version, you must inform L^AT_EX of that fact by using the `\SetMathAlphabet` command. For example, in the default setup the `\mathsf` alphabet identifier is defined as follows:

```
\DeclareMathAlphabet{\mathsf}{OT1}{cmss}{m}{n}
\SetMathAlphabet{\mathsf}{bold}{OT1}{cmss}{bx}{n}
```

The first line means that the default for `\mathsf` in all math versions is Computer Modern Sans medium. The second line states that the bold math version should use the font Computer Modern Sans bold extended instead.

```
\SetMathAlphabet{cmd}{version}{encoding}{family}{series}{shape}
```

From the previous example, you can see that `\SetMathAlphabet` takes six arguments: the first is the name of the math alphabet identifier, the second is the math version name for which you are defining a special setup, and the other four are the encoding, family, series, and shape name with which you are associating it.

As noted earlier, you can redefine an existing math alphabet identifier by using `\DeclareMathAlphabet`. If you do so, all previous `\SetMathAlphabet` declarations for this identifier are removed from the internal tables of L^AT_EX. Thus, the identifier comes out the same in all math versions unless you add new `\SetMathAlphabet` declarations for it.

9.5 Standard L^AT_EX font support

This section opens with a short introduction to the standard text fonts distributed together with L^AT_EX, which are Computer Modern, European Computer Modern, and Latin Modern, as well as a brief introduction to the legacy and the modern support packages for core PostScript fonts (Chapter 10 shows samples of them and many other font families now available in L^AT_EX).

Family	Series	Shapes	Typeface Examples
<i>Computer Modern Roman</i> (Encodings: T1, TS1, OT1)			
cmr	m	n, it, sl, sc, ui	Computer Modern Roman, <i>italic</i> , <i>slanted</i> , and SMALL CAPS
	bx	n, it, sl, sc	bold extended , <i>italic</i> , <i>slanted</i> , and SMALL CAPS
	b	n	bold medium width (no other shapes)
<i>Computer Modern Sans</i> (Encodings: T1, TS1, OT1)			
cmss	m, bx	n, (it), sl	Computer Modern Sans bold extended , <i>italic</i> , and <i>slanted</i>
	sbc	n	Computer Modern Sans semibold condensed (no shape variants)
<i>Computer Modern Typewriter</i> (Encodings: T1, TS1, OT1)			
cmtt	m	n, it, sl, sc	Comp. Mod. Typewriter, <i>italic</i> , <i>slanted</i> and SMALL CAPS
cmvtt	m	n, it	Comp. Mod. Typewriter proportional upright and italics
<i>Computer Modern Fibonacci</i> (Encodings: T1, OT1)			
cmfib	m	n	Computer Modern Fibonacci
<i>Computer Modern Dunhill</i> (Encodings: T1, OT1)			
cmdh	m	n	Computer Modern Dunhill

Values in blue are not or only partly offered in OT1 encoding!

Table 9.5: Classification of the Computer Modern font families

It is followed by a discussion of \LaTeX 's standard support packages for input and font encodings including a discussion of how to use an extended set of text symbols. The section concludes by describing a package for tracing \LaTeX 's font processing and another package for displaying glyph charts (a package the author used extensively while preparing the later parts of this chapter).

9.5.1 Computer Modern, Latin Modern — The \LaTeX standard fonts

Original \TeX font encoding

Along with \TeX , Donald Knuth developed a family of fonts called Computer Modern; see Table 9.5. Until the early 1990s, essentially only these fonts were usable with \TeX and, consequently, with \LaTeX . Each of them contains 128 glyphs (\TeX was working with 7 bits originally), which does not leave room for including accented characters as individual glyphs. Thus, using these fonts means that accented characters have to be produced with the `\accent` primitive of \TeX , which in turn means that automatic hyphenation of words with accented characters is impossible. While this restriction is acceptable for English documents that contain few foreign words, it is a major obstacle for other languages.

Not surprisingly, these deficiencies were of great concern to the \TeX users in Europe and eventually led to a reimplementa-tion of \TeX in 1989 to support 8-bit

characters internally and externally. At the T_EX Users conference in Cork (1990), a standard 8-bit encoding for text fonts (T1) was developed that contains many diacritical characters (see Table 9.22 on page 763) and allows typesetting in more than 30 languages based on the Latin alphabet. At the University of Bochum (under the direction of Norbert Schwarz) the Computer Modern font families were then reimplemented, and additional characters were designed, so that the resulting fonts completely conform to this encoding scheme. The first implementation of these fonts was released under the name “DC fonts”. Since then Jörg Knappen has finalized them, and they are now distributed as “European Computer Modern Fonts”, often shortened to “EC fonts”.

*T1 a.k.a. “Cork”
encoding*

EC fonts

Both Computer Modern and the EC fonts are considered standard in L^AT_EX and must be available at any installation. Although originally developed with METAFONT, there are free Type 1 PostScript replacements as well. For Computer Modern these were produced by Blue Sky Research; Y&Y added the L^AT_EX, AMS, and Euler fonts. The EC fonts were converted in 2001 from METAFONT sources to Type 1 PostScript by Vladimir Volovich. His implementation is called the CM-Super fonts package and, besides the EC fonts, it covers EC Concrete, EC Bright, and LH fonts (Cyrillic Computer Modern). In addition to the T1 encoding, the L^AT_EX standard encodings TS1, T2A, T2B, T2C, and X2 are supported by CM-Super. The CM-Super fonts were automatically converted to the Type 1 format, and although a sophisticated algorithm was used for this conversion, you cannot expect exactly the same quality as could be achieved by a manual conversion process.

*PostScript Type 1
instances*

CM-Super fonts

Since the PostScript fonts have the same font metrics as their METAFONT counterparts, they need no support package in the L^AT_EX document. They are now provided by virtually all distributions and are automatically used by pdfT_EX or the driver program (e.g., dvips) that converts the .dvi output to PostScript.

To avoid the generation of too many bit-mapped fonts, the standard .fd files for Computer Modern and European Computer Modern provided only a handful of well-defined font sizes. This is still the default even though with PostScript outline fonts it would be possible to typeset in arbitrary sizes without problems.¹ Thus, if you ask for an intermediate size (via `\fontsize`), you get a warning, and the nearest available size is chosen instead. To lift this restriction you can make use of the package `fix-cm` or use the Latin Modern fonts instead as discussed below.

Although the EC fonts were originally meant to be a drop-in extension (and replacement) for the 7-bit Computer Modern fonts, not all glyph shapes have been kept in the end. For example, the German “ß” got a new design — a decision by the font designer that did not make everybody happy (me included).

 *Issues
with the EC fonts*

```
\fontencoding{OT1}\fontfamily{cmr}\selectfont
Computer Modern sharp s: ß
```

Computer Modern sharp s: ß
EC Modern sharp s: ß

```
\fontencoding{T1}\fontfamily{cmr}\selectfont
EC Modern sharp s:      ß
```

9-5-1

¹The set of fixed sizes has been kept as the default to ensure that older documents do not change their appearance if reprocessed.

However, these were not the only differences between the original Computer Modern fonts and the new EC fonts. The latter have many more individual designs for larger font sizes (while CM fonts were scaled linearly), and in this respect the fact that both really are different font families is quite noticeable.¹ The particular example that follows is perhaps the most glaring difference of that kind:

The fox jumps

quickly over the fence!

The fox jumps

quickly over the fence!

```
\fontencoding{OT1}\sffamily\bfseries
\Huge      The fox jumps \par
\normalsize quickly over the fence!\par
\fontencoding{T1}\sffamily\bfseries
\Huge      The fox jumps \par
\normalsize quickly over the fence!\par
```

9-5-2

These differences are no problem if one likes the EC designs and uses T1 throughout. Otherwise, a number of approaches can be taken to resolve this problem. One is to employ a different set of font definitions that do not make use of *all* individual EC font designs and that are closer to those of the traditional CM fonts, but with improved typographical quality. Such a solution is provided by Walter Schmidt's (1960–2021) package `fix-cm`, which is distributed as part of the core \LaTeX distribution. Load this package directly after the document class declaration (or even before using `\RequirePackage`), because it takes effect only for fonts not already loaded by \LaTeX — and the document class might load fonts.

*Latin Modern — the
modern replacement
for CM or EC fonts*

In 2002, three European \TeX user groups (DANTE, GUTenberg, and NTG) initiated and funded a project to integrate all of the variants of the Computer Modern Roman typefaces into a single Latin Modern family of fonts. The project was carried out by Bogusław Jackowski and Janusz Marian Nowacki (1951–2020), and the first official version of the Latin Modern fonts was presented at the DANTE meeting in 2003.

The **Latin Modern** fonts are carefully handcrafted PostScript Type 1 fonts based on the designs of Knuth's *Computer Modern* families. They contain all the glyphs needed to typeset Latin-based European languages as well as glyphs for Native American, Vietnamese, and Transliterations.

```
\usepackage[T1]{fontenc} \usepackage{lmodern}
The \textbf{Latin Modern} fonts are carefully
handcrafted PostScript Type-1 fonts based on
the designs of Knuth's \emph{Computer Modern}
families. They contain all the glyphs needed
to typeset Latin-based European languages as
well as glyphs for Native American, Vietnamese,
and Transliterations.
```

9-5-3

Already then the fonts were in fact a huge extension in terms of glyph coverage with additional diacritical characters covering many scripts based on the \LaTeX character set. The font classification of Latin Modern is listed in Table 9.6 on the facing page. It shows that some of the “funny” fonts got dropped, but at the same time several

¹The historical mistake was to pretend to NFSS that both are the same families (e.g., `cmr`, `cms`), just encoded according to different font encodings. Unfortunately, this cannot be rectified without huge backward compatibility problems.

Family	Series	Shapes	Typeface Examples
<i>Latin Modern Roman</i>		Latin Modern Roman Latin Modern Roman Caps	(Encodings: T1, TS1, OT1, T5, LY1, and TU)
lmr	m	n, it, sl, sc, scsl , ui	Latin Modern Roman upright, <i>italic</i> , <i>slanted</i> , SMALL CAPS and <i>SMALL CAPS SLANTED</i>
	bx	n, it, sl	Latin Modern bold extend, <i>italic</i> , and <i>slanted</i>
	b	n, (it), sl	Latin Modern bold <i>and slanted</i>
<i>Latin Modern Sans</i>		Latin Modern Sans	(Encodings: T1, TS1, OT1, T5, LY1, and TU)
lmss	m	n, (it), sl	Latin Modern Sans upright and <i>slanted</i>
	(b), bx, sbc	n, (it), sl	Latin Modern Sans bold extended <i>and slanted</i> , and semibold condensed <i>and slanted</i>
<i>Latin Modern Typewriter</i>		Latin Modern Mono	(Encodings: T1, TS1, OT1, T5, LY1, and TU)
lmtt	m	n, it, sl, sc, scsl	Latin Modern Typewriter upright, <i>italic</i> , <i>slanted</i> , SMALL CAPS and <i>SMALL CAPS SLANTED</i>
	l, lc, b, (bx)	n, (it), sl	Latin Modern Typewriter light, <i>slanted</i> , and light condensed, <i>slanted</i> , bold and bold slanted
<i>Proportional Latin Modern Typewriter</i>		Latin Modern Mono Prop	(Encodings: T1, TS1, OT1, T5, LY1, and TU)
lmttt	m	n, (it), sl	Latin Modern Typewriter proportional <i>and slanted</i>
	l, b, (bx)	n, (it), sl	Latin Modern Typewriter light, <i>light slanted</i> , bold and bold slanted
<i>Latin Modern Dunhill</i>		Latin Modern Roman Dunhill	(Encodings: T1, TS1, OT1, T5, LY1, and TU)
cmdh	m	n, (it), sl	Latin Modern Dunhill upright <i>and slanted</i>

Shapes or series value colored in blue are additions in the Latin Modern family not available in the Computer Modern. Values given in parentheses indicate substitutions; e.g., (*it*) produces **sl**, and (b) becomes **bx**, or vice versa. Note that the CM proportional typewriter has an **it** shape while the LM proportional typewriter has an **sl** shape instead. The font names with gray background are for use with the fontspec package in Unicode engines.

Table 9.6: Classification of the Latin Modern font families

additional shapes and weights were added [171]. In particular, there are now bold and light versions of the typewriter fonts that can be useful in certain situations.

However, without accompanying math fonts, they were not yet a full-fledged alternative to Computer Modern or European Modern fonts. This changed in 2011 with the release of the Latin Modern Math fonts. Additionally, all fonts in the Latin Modern families were made available in OpenType font format, which made them available to be used in Unicode T_EX engines (or even Word, if so desired).

Unicode engines

In fact, they are now L^AT_EX's default fonts if you typeset using X_YL^AT_EX or LuaT_EX.

In 8-bit engines (e.g., pdf \TeX) Computer Modern in OT1 encoding remained the default to ensure backward compatibility for the huge amount of existing documents in archives. As previously mentioned, the OT1 encoding has noticeable defects with respect to glyph coverage, hyphenation, and online search in formatted documents for all Latin-based languages (except English). This was repaired with the EC fonts, but their Type 1 versions did not quite reach the highest quality of hand-crafted fonts due to their generation process.

All this is now resolved with the Latin Modern fonts; you only have to load the `lmodern` package and additionally make T1 your default font encoding as we did in the previous example.

With Latin Modern fonts in combination with the T1 encoding, diacritical characters, hyphenation, and online search are well supported; furthermore, the fonts use the same set of design sizes as the original CM fonts, and the original shape of the sharp s is back. Thus, examples such as 9-5-1 or 9-5-2 come out just fine, and we therefore recommend that for new documents you use `lmodern` (in T1 encoding) with pdf \TeX if you want to typeset in a “Computer Modern like” typeface.

The fox jumps quickly over the fence!

A Latin Modern sharp s: ß

```
\usepackage[T1]{fontenc} \usepackage{lmodern}
\sffamily\bfseries\Huge The fox jumps \par
\normalsize quickly over the fence! \par
\normalfont A Latin Modern sharp s: ß
```

9-5-4

The `lmodern` package supports three options: `lighttt` changes `\ttdefault` to select the light typewriter, while `variablett` uses the proportional typewriter face. By default the package also changes the math font setup to use Latin Modern Math fonts. If this is not desirable (because you use other fonts for mathematics), use the option `nomath` to prevent it.

9.5.2 PSNFSS and \TeX Gyre — Core PostScript fonts for \LaTeX

The PostScript New Font Selection Scheme (PSNFSS) bundle, originally developed by Sebastian Rahtz (1955–2016), was the first major application using the \LaTeX font selection scheme to provide support for common PostScript fonts, covering the “Base 35” fonts (which are built into any Level 2 PostScript printing device and the `ghostscript` interpreter) and the free Charter and Utopia fonts. After Sebastian’s death, Walter Schmidt (1960–2021) maintained PSNFSS, and today it is maintained by Keiran Harcombe, who has taken over all of Walter Schmidt’s packages.

These days it is, however, largely superseded by the development of the \TeX Gyre fonts (by Bogusław Jackowski and Janusz Marian Nowacki (1951–2020)) that provide reimplementations of many of these fonts with an extended glyph set so that essentially all Latin-based languages are now supported. The Vietnamese glyphs in this collection have been added by Hàn Thế Thành. The basic Greek symbols are based on earlier work by Apostolos Syropoulos and Antonis Tsolomitis. Like the Latin Modern fonts, the \TeX Gyre project was initiated and funded by several European \TeX user groups.

<i>Package</i>	<i>Roman Font</i>	<i>Sans Serif Font</i>	<i>Typewriter Font</i>	<i>Formulas</i>
—	CM Roman	CM Sans Serif	CM Typewriter	CM Math
lmodern	LM Roman	LM Sans Serif	LM Typewriter	LM Math
tgbonum	Bookman (Bonum)			
tgchorus	Zapf Chancery (Chorus)			
tgpagella	Palatino (Pagella)			
tgschola	New Century Schoolbook (Schola)			
tgtermes	Times Roman (Termes)			
tgadventor	Avant Garde (Adventor)			
tgheros	Helvetica (Heros)			
tgcursor	Courier (Cursor)			

Names in parentheses are the font names used by the T_EX Gyre foundry.

Table 9.7: T_EX Gyre packages for setting up fonts

Since it is in nearly all circumstances better to use the T_EX Gyre fonts than to typeset using the far more restricted fonts offered by the original PSNFSS setup, we focus in the remainder of this section on the newer developments and discuss only those packages from PSNFSS that are still relevant. Samples of the font families, together with many other fonts available today, are given in the next chapter.

For normal use you probably have to include only one (or more) of the packages listed in Table 9.7 to change the default roman, sans serif, and/or typewriter typefaces. If you study this table, you will notice that, with the exception of lmodern, the packages change only the text fonts. For packages that also load matching math fonts see Section 12.5 on page →II 261.

The T_EX Gyre font packages all offer a number of options that allow you to combine them in a way that different fonts have the same height, either matching the uppercase letter height (option `matchuppercase`) or the x-height (option `matchlowercase`) of the roman font. Thus, a document with a line like

```
\usepackage{tgtermes,tgcursor}
\usepackage[matchuppercase]{tgheros}
```

in the preamble would be typeset in Times, Courier, and Helvetica with heights matching the uppercase letters of Times Roman. Loading Helvetica at its default height instead would not at all blend well, because the characters are far too large compared to Times. Alternatively, you can use the key/value option `scale` to set an

*Scale T_EX Gyre fonts
to blend with
surrounding fonts*

explicit scale factor during the package load. The next example shows a probably more pleasing combination using Bookman and Avant Garde fonts.

```
\usepackage[matchlowercase]
      {tgbonum,tgadventor,tgcursor}
```

This example shows Bookman combined with Avant Garde and Courier with *the x-height of all fonts being matched thanks to the option matchlowercase*.

This example shows Bookman combined with `\textsf{Avant Garde}` and `\texttt{Courier}` with `\emph{the x-height of all fonts being \textsf{matched}}` thanks to the option `\texttt{matchlowercase}}`.

9-5-5

*Word space
adjustments*

The word spaces in some of the T_EX Gyre fonts are a little different (tighter) to those of the originals, and if you do not like that, you can use the option `oldspacing`, which is understood by all T_EX Gyre packages.

*Using condensed
Helvetica*

Finally, the `tgheros` package has one further option, `condensed`, that when used loads Helvetica Narrow instead of Helvetica if that is preferred.

*Sans serif as
document typeface*

By default, L^AT_EX selects a roman typeface as the document font. Packages such as `tgheros` or `tgadventor` change the default sans serif typeface (by changing the `\sfdefault` value) but do not change the default document font family. If such a typeface should be used as the document font, issue the line

```
\renewcommand\familydefault{\sfdefault}
```

in the preamble of your document.

*Use the T_EX Gyre
packages instead
of PSNFSS where
applicable*

The packages from the PSNFSS bundle are listed in Table 9.8 on the facing page. They have (unfortunately) the more memorable names and have been heavily used in the past, so you may come across one or the other in older documents. However, these days none of them can really be recommended, so the second column of the table suggests replacements. The packages in the first block set up individual fonts like the T_EX Gyre packages, but because their packages offer better versions of these fonts, it is usually preferable to use them instead. The packages in the second part of the table should definitely be avoided (or replaced if already used in documents). Either they combine fonts without adjusting their heights (see discussion above) or they attempt to set up matching math fonts using only partially suitable fonts, and for this better possibilities are now available; see Chapter 10. Of course, if you replace, say, `palatino` and want it matched with Helvetica (which is a questionable choice in the first place), then you now have to load `tpagella` and `tgheros` with a suitable option to match up the font sizes. The final block shows packages that combine text and math fonts, but again there are now much better solutions available (discussed in Chapter 12), so if you come across these packages in older documents, consider replacing them (except perhaps for `mathpazo`).

Besides `mathpazo` there is really only one other font support package in the PSNFSS collection that is still interesting these days: the `pifont` package. It does not change any text fonts but sets up various commands for use with so-called Pi fonts (i.e., special symbol fonts like Zapf Dingbats). It is described in Section 10.13.1 on page →II 113.

<i>Package</i>	<i>replace with</i>	<i>Roman Font</i>	<i>Sans Serif Font</i>	<i>Typewriter Font</i>	<i>Formulas</i>
charter	XCharter ^a	Charter			
utopia	erewhon ^a	Utopia			
chancery	tgchorus	Zapf Chancery			
helvet	tgheros		Helvetica		
avant	tgadventor		Avant Garde		
courier	tgcursor			Courier	
<i>Deprecated Packages</i>					
bookman	tgbonum	Bookman	Avant Garde	Courier	
newcent	tgschola	New Century Schoolbook	Avant Garde	Courier	
palatino	tgpagella	Palatino	Helvetica	Courier	
times	tgtermes ^b	Times	Helvetica	Courier	
<i>Packages with math setup (most are not recommended, see Chapter 12)</i>					
mathpazo		Palatino			Palatino + Pazo
mathptmx	newtxmath ^c	Times			Times + Symbol
mathptm	newtxmath ^c	Times			Times + Symbol + CM
mathpple	mathpazo	Palatino			Palatino + Symbol + Euler

^aThese fonts have not been redone by T_EX Gyre, but there exist improved versions by others; see Sections 10.5.6 and 10.5.23 for details.

^bTo mimic the times package you also need to load tgheros and tgcursor or you can consider using newtxtext plus an appropriate typewriter family instead.

^cPlus adding newtxtext or tgtermes for the text font setup.

Table 9.8: PSNFSS packages for setting up fonts

9.5.3 A note on baselines and leading

Most document classes designed for use with Computer Modern set up a leading (`\baselineskip`) of 10pt/12pt. This may appear to be too tight for several of the PostScript font families shown below, due to a larger x-height of the fonts. However, because this is a matter of document design and also depends on the chosen line width and other factors, the packages in the T_EX Gyre or PSNFSS collection make no attempt to adjust the leading. For a given document class you can change the leading by a *factor* by issuing the declaration `\linespread{factor}` in the preamble. For example, `\linespread{1.033}` would change the leading from, say, 12pt to approximately 12.4pt.

For best results, however, one needs to use a document class designed for the selected document fonts or, lacking such a class, to redefine the commands

Adjusting the leading

`\normalsize`, `\footnotesize`, and so on (see page 665 for details). Also remember that changing the leading might result in a noticeable number of “Underfull \vbox” warnings, if the `\textheight` is no longer an integral number of text lines (see page →II 763 for further details).

9.5.4 inputenc — Explicitly selecting the input encoding

As mentioned earlier, the development of the `inputenc` package made it possible to use many accented characters, either via single keystrokes or by some other input method (e.g., by pressing ‘ and then a to get â) in your source instead of having to type `\‘a`, `\^e`, and so forth.

To enable this, all you had to do was to load the package and specify the input encoding¹ used by your computer as a package option. Once done, the document is processed correctly on any L^AT_EX installation even if the source file looks strange on some computers due to the encoding differences.

For example, the Russian text Русский язык (Russian language) written in the once popular `koi8-r` encoding would display in an editor program on a German computer (using the `latin1` encoding) partially scrambled as

òÕÓÓÊÊ ÑÜË (Russian language)

However, with the help of `\usepackage[koi8-r]{inputenc}` in the preamble of the document, a L^AT_EX run always produces “Русский язык (Russian language)”, i.e., the desired result.

Originally the `inputenc` package was written to describe the encoding used for a document as a whole — hence the use of options in the preamble. It is, however, possible to change the encoding in the middle of a document by using the command `\inputencoding`. This command takes an encoding name as its argument. Processing is rather computing intensive, as typically more than 120 characters are remapped each time. Nevertheless, we know of applications that change the encoding several times within a paragraph yet seem to work reasonably well.

*UTF-8 support,
nowadays the
default*

Besides such single-byte encodings, `inputenc` also enabled UTF-8 support through the option `utf8`. Because nearly all computer operating system nowadays use UTF-8 as their standard encoding, L^AT_EX changed in 2015 and made this encoding the default. It is therefore only necessary to load the `inputenc` package if this assumption is wrong, either because you happen to use an older computer whose operating system is still 8-bit with some particular code page in force or because you reprocess an old document stored in one of the legacy 8-bit encodings (in which case it hopefully already contains the appropriate `inputenc` line).

¹The base set of supported encodings (more than two dozen) is documented in the `inputenc` package documentation; apart from UTF-8, the most important ones are probably `latin1` to `latin4` (ISO 8859-1 to ISO 8859-4 [72]) and `latin9` (ISO 8859-15) that can represent most Western and Eastern European languages. Also supported are the Windows OS code pages `cp1250` (Central and Eastern Europe), `cp1252` (Western Europe), and `cp1257` (Baltic). In some cases, language packages for Babel provide additional encoding configuration files for `inputenc`. For example, encodings related to the Cyrillic languages are distributed together with the corresponding font support packages for Cyrillic.

If you process a document stored in one of the legacy encodings that is missing an appropriate inputenc line, three things can happen:

- If the document consists only of ASCII characters, then it is in fact a proper UTF-8 document, and it processes correctly.
- The worst-case scenario is that the file is processed without any errors (i.e., it is technically a UTF-8 file) but the printed output is wrong in some places. While this is not likely, it can happen, and there is no way to automatically detect that (obviously L^AT_EX cannot check the results for scrambled/nonsense words).
- The most likely case, however, is that you receive one or more error messages of the type “Invalid UTF-8 byte” indicating that L^AT_EX found a byte sequence that is not allowed in a UTF-8 file. Such errors are therefore fairly certain indicators that the file is not encoded in UTF-8, but in some legacy encoding. Finding out in which encoding can unfortunately be a difficult task, if you do not happen to know on which computer the file was made. You may have to make an educated guess, process the file, and then carefully check the printed result—the fact that you do not get any errors after selecting an encoding, such as `latin1`, is unfortunately no proof that it is the correct one.

Other indicators that the file is in a legacy encoding are error messages of the type “Unicode character ... not set up for use with L^AT_EX”. However, these errors can also show up with proper UTF-8 files if the Unicode character in question is not available in any of the loaded fonts.

9.5.5 fontenc—Selecting font encodings

To be able to use a text font encoding with L^AT_EX, the encoding has to be loaded in the document class, in a package, or in the document preamble. More precisely, the definitions to access the glyphs in fonts with a certain encoding have to be loaded. The canonical way to do this with an 8-bit T_EX engine; e.g., pdfT_EX is via the fontenc package, which takes a comma-separated list of font encodings as a package option. The last of these encodings is automatically made the default document encoding. For example,

```
\usepackage[T2A,T1]{fontenc}
```

loads all necessary definitions for the Cyrillic¹ T2A and the T1 (Cork) encodings and sets the latter to be the default document encoding by changing `\encodingdefault`.

In contrast to normal package behavior, one can load this package several times with different optional arguments to the `\usepackage` command. This is necessary to allow a document class to load a certain set of encodings and enable the user to load still more encodings in the preamble. Loading encodings more than once is

 Multiple uses of
fontenc allowed

¹If any Cyrillic encoding is loaded, the list of commands affected by `\MakeUppercase` and `\MakeLowercase` is automatically extended.

possible without side effects (other than potentially changing the document default font encoding).

If language support packages are used in the document (e.g., those coming with the babel system), it is often the case that the necessary font encodings are already loaded by the support package.

*Do not
use fontenc in
Unicode engines
unless there is a
good reason*

Unicode engines

It is, however, not required to use the fontenc package together with a Unicode engine, such as Xe_{La}TeX or Lua_{TeX} — in fact it is usually wrong and can lead to missing or wrong characters and to incorrect hyphenation!

In Unicode engines the assumption is that fonts are Unicode fonts, i.e., encoded in the TU encoding, so this encoding is automatically made the default encoding by \LaTeX when the program starts.

While it is possible to use fonts that have a different encoding such as T1 in Unicode engines, one has to be aware that only ASCII characters (and those are in the same slot position in Unicode and in the current font encoding) can be entered directly. For all others you need to use their LICR representations; see Table 9.23 on page 768. For example, `\"a` works always, while `ä` works only in T1 but not in OT1. For `ß` or `€` the situation is worse; they work in none of the legacy encodings and produce either wrong output (like `SS`) or no output at all — for them you have to always use `\ss` and `\texteuro`.

Furthermore, even if you correctly input your text using LICRs where necessary, hyphenation of your text is still likely to produce incorrect results. The problem is that in all \TeX programs the patterns used to determine the hyphenation points depend not just on the language but also on the font encoding in force.

So for fully correct hyphenation you need a set of patterns for each language/font encoding combination, which is not realistic. Thus, \TeX assumes one dominant encoding per language, which works well enough if encodings are similar (e.g., OT1 is more or less a subset of T1) but less so many characters are simply in different slots.

If you need to use fontenc for some reason, make sure that the default encoding (i.e., the one used for the text fonts) remains TU; that is, always list TU as the last option when loading (or reloading) the package.

9.5.6 Additional text symbols not part of OT1 or T1 encodings

When the T1 font encoding was defined in Cork, it was decided that this encoding should omit many standard text symbols such as `†` and instead include as many composite glyphs as possible. The rationale was that characters that are subject to hyphenation have to be present in the same font, while one can fetch other symbols without much penalty from additional fonts. These extra symbols have, therefore, been collected in a companion encoding. In 1995, a first implementation of this encoding (TS1) was developed by Jörg Knappen [80, 81]. With the textcomp package, Sebastian Rahtz (1955–2016) provided a \LaTeX interface to it.

Unfortunately, just as with the T1 encoding, the encoding design for TS1 was prepared based on glyph availability in the T_EX world without considering that the majority of commercial fonts provide different sets of glyphs. As a result, the full implementation of this encoding is available for very few font families, among them EC, CM Bright, and Latin Modern fonts. For most PostScript fonts, implementations of the encoding also exist, but a larger number of the glyphs are missing and produce square blobs of ink or possibly just a gap in the typeset output.¹ Table 9.9 on pages 696–697 shows the glyphs made available by TS1 and the commands to access them. Commands colored in blue indicate that the corresponding glyph is most likely not available in the font design when PostScript or OpenType fonts are used.

Since 2020 the symbols provided by the TS1 encoding are directly accessible from L^AT_EX without the need to load the `textcomp` package any longer. The package is still available so that older documents work without complaining about a missing package.

Unicode engines

In Unicode engines the additional commands have always been available (adjusted to select slots in the Unicode TU encoding) if supported by the font, so it was never necessary to load the `textcomp` package with those engines.

The symbols provided with the encoding TS1 should normally switch their design depending on the current font settings. A few of them have been already present in the original Computer Modern fonts, hidden in the math fonts (e.g., `\textbullet`, or `\textdagger`), and L^AT_EX releases prior to the development of the TS1 encoding always took them from there. Nowadays they are fetched from the companion fonts and as a consequence, they sometimes change their shape when the surrounding font attributes (family, series, or shape) are changed just like any other text character, allowing them to better blend in with surrounding text.

	<code>\newcommand\sample{\textdagger~\textdaggerdbl~\textparagraph ~\textbullet~\textbardbl~\textasteriskcentered~\textsection}</code>	
† ‡ ¶ • * § (CM fonts)		<code>\sample\</code> (CM fonts) <code>\\</code>
† ‡ ¶ • * § (Alegreya)	<code>\fontfamily{Alegreya-LF}\upshape</code>	<code>\sample\</code> (Alegreya) <code>\\</code>
† ‡ ¶ • * § (<i>Alegreya italics</i>)		<code>\itshape \sample\</code> (Alegreya italics) <code>\\</code>
† ‡ ¶ • * § (Gillius)	<code>\fontfamily{GilliusADF-LF}\upshape</code>	<code>\sample\</code> (Gillius)

9-5-6

While this is usually the right solution, it may result in changes in unexpected places. For example, the `itemize` environment by default uses `\textbullet` and `\textasteriskcentered` to indicate first-level and third-level items. And in all likelihood you do not want those to change just because you typeset a few items using, for example, `\itshape`. Similarly, footnote symbols, if used instead of numbered footnotes, should probably have the same glyph shapes regardless of local font settings for the text. For this reason the footnote marker uses `\normalfont` to ensure that the markers are always typeset using the same font face.

¹The T1 encoding has the same problem when it comes to older PostScript fonts, but fortunately only five (seldom used) glyphs are missing from some fonts; see Example 9-7-1 on page 737.

Blue indicates that the symbol is unavailable in some fonts. The TS1 subencoding from which on the glyph is substituted with a default is given in parentheses. Most modern font families have subencodings 2–5.

Table 9.9: Commands made available with the TS1 encoding (cont.)

Similarly `\labelitemi` to `\labelitemiv` reset the font face, but in this case it is done indirectly by executing `\labelitemfont`, which by default is defined to call `\normalfont`. This allows altering the behavior by redefining this command; e.g.,

```
\renewcommand\labelitemfont{\fontseries{m}\fontshape{n}\selectfont}
```

uses the current font family to fetch the symbols but with a fixed series and shape value.

By specifying `\UseLegacyTextSymbols` in the preamble, it is also possible to direct L^AT_EX to use the eight fixed symbols from the math fonts in all situations. They are then used in `itemize` and footnotes, but also in running text as shown in the next example. It also changes `\oldstylenums` to always use the single set of oldstyle numbers from the math fonts and is really only provided for backward compatibility.

Using legacy text symbols

```

* || • † ‡ ¶ · § 123  \UseLegacyTextSymbols  \newcommand\legacysyms{\textasteriskcentered~%
* || • † ‡ ¶ · § 123  \textbardbl~\textbullet~\textdagger~\textdaggerdbl~\textparagraph~%
* || • † ‡ ¶ · § 123  \textperiodcentered~\textsection~\oldstylenums{123}}
* || • † ‡ ¶ · § 123  \fontfamily{Alegreya-LF}\upshape \legacysyms \ \ \itshape \legacysyms \ \
9-5-7 * || • † ‡ ¶ · § 123  \fontfamily{NotoSans-LF}\upshape \legacysyms \ \ \itshape \legacysyms

```

As you see, the symbols are now always identical regardless of the font selected. However, the spacing differs because the space characters have a different width in Alegreya and Noto Sans.

If you want to use only some of the legacy symbols, for example the “§” because you prefer the original design, or the “•” for `itemize` because the design in Alegreya “.”, for example, appears to be too tiny, then this is easily possible too. All eight symbols can be accessed by using `\textlegacybullet` instead of `\textbullet`,

etc., and if you always want to use the legacy symbol, you can adjust the definition like it was done for `\textdagger` in the example.

We prefer † and § over ‡ and §. And • is now always legacy design. `\usepackage{Alegreya}` `\DeclareTextSymbolDefault{\textbullet}{OMS}`
 † and §. And • is now always legacy design. We prefer `\textlegacydagger` and `\textlegacysection` over `\textdagger` and `\textsection`. And `\textbullet` is now always legacy design.

9-5-8

The precise interface for `\DeclareTextSymbolDefault` is discussed in Section 9.9.4 on page 765.

Special features

*Diacritics on
uppercase letters*

Diacritical marks on uppercase letters are sometimes flattened in some font designs compared to their lowercase counterparts. Fonts derived from Computer Modern designs, e.g., the EC fonts, CM Bright or Latin Modern, follow this tradition. For example, the grave accents on ò and Ò are different (which is not the case with Lucida, the document font used in this book). This poses a problem if one needs an uncommon letter that is not available as a single glyph in the T1 encoding, but rather must be constructed by placing the diacritical mark over the base character. In that case the same diacritical mark is used, which can result in noticeable differences (see the \ddot{X} in the next example). The `\capital...` accents shown in Table 9.9 on page 696 solve this problem by generating diacritical marks suitable for use with uppercase letters.

ò \grave{X} Ò \grave{X} Ò \grave{X}
 ò \grave{X} Ò \grave{X} Ò \grave{X}

```
\usepackage[T1]{fontenc}
\huge \o'x \O'X \capitalgrave O\capitalgrave X \par
\fontfamily{Alegreya-LF}\selectfont
\o'x \O'X \capitalgrave O\capitalgrave X
```

9-5-9

Flat accents are available only with a handful of font families, e.g., Computer Modern and closely related designs. With all others, the capital accents produce the same accents as on lowercase letters, but this has the effect that they then appear on all glyphs, which can be observed in the second line of the example.

Unicode engines

In Unicode engines the `\capital...` accents always produce the same results as the normal accent commands and leave it up to the font how the accent is positioned. It therefore makes no sense to use them with these engines. They are provided only to avoid error messages with documents written for pdf \TeX and reprocessed with $\text{X}\mathbb{T}_{\text{E}}\text{X}$ or Lua TeX .

*Compound word
marks of different
heights*

$\text{L}\mathbb{T}_{\text{E}}\text{X}$ offers a `\textcompwordmark` command, an invisible zero-width glyph within the T1 encoding that can, for example, be used to break up unwanted ligatures (at the cost of preventing hyphenation).¹ The glyph has a height of 1ex, which makes it possible to use it as the argument to an accent command, thereby

¹With OT1-encoded fonts it is a faked glyph and therefore prevents automatic hyphenation in the word in which it is used.

placing an accent between two letters. In the next example this command is used to produce the German -burg abbreviation. With the TS1 encoding two additional compound word marks become available: `\textascendercompwordmark` and `\textcapitalcompwordmark` that have the height of the ascender or capitals in the font, respectively.

	<code>\usepackage[T1]{fontenc}</code>
<code>b~g</code> (this fails)	<code>b\u{ }g</code> (this fails) <code>\\ Auf\textcompwordmark lage not Auflage \\</code>
Auflage not Auflage	<code>b\u\textcompwordmark g \quad B\u\textcapitalcompwordmark G</code>
	<code>and \fontfamily{Alegreya-LF}\selectfont</code>
<code>b̃g BG and b̃g BG</code>	<code>b\u\textcompwordmark g \quad B\u\textcapitalcompwordmark G</code>

9-5-10

The above example works only in pdfL^AT_EX, and to allow for hyphenation in the word “Auflage” you would need to use T1-encoded fonts, because only such fonts contain a real compound-mark glyph. If a font in a different encoding is used, then the glyph is fetched from a matching T1-encoded font, and that breaks hyphenation.

Unicode engines

The fonts for Unicode engines using the TU encoding are lacking the special glyphs `\textcapitalcompwordmark` and `\textascendercompwordmark`, but in addition they also use a different mechanism to place accents so that the “-burg” accent comes out wrong with most fonts. However, the command `\textcompwordmark` can still be used to break up ligatures.

The TS1 encoding offers several monetary symbols, among them a \$ sign, but because that glyph is also available in both the OT1 and T1 encodings, there is no point in removing its definition and forcing L^AT_EX to pick up the TS1 version if you are typesetting in either of these encodings. However, assume you want to use the variant dollar sign $\text{\$}$ for your dollars automatically. In that case you have to get rid of the declarations in other encodings so that L^AT_EX automatically switches to TS1.

*Managing your
dollars*

```
\DeclareTextCommandDefault{\textdollar}
  {\UseTextSymbol{TS1}\textdollaroldstyle} % set up new default
\UndeclareTextCommand{\textdollar}{OT1}    % do not use the defs
\UndeclareTextCommand{\textdollar}{T1}     % in OT1 or T1
```

Such redeclarations will, of course, work properly only if the document fonts contain the desired glyph in the TS1 encoding. In this book they would have failed, because Lucida Bright (the document font for this book) has only the restricted set of ISO-Adobe symbols available in TS1. If you wonder where the $\text{\$}$ and similar symbols shown in the book actually came from, the answer is simple: from the Latin Modern fonts.

Unicode engines

The same approach can be taken in Unicode engines; you only have to undeclare `\textdollar` in the TU encoding then. If the current font family is not available in TS1 encoding (which is the most common case for Unicode fonts), then a default font is chosen, which in the case of Unicode engines is Latin Modern.

Typesetting oldstyle numerals

For most other glyphs it is enough to change the default because they are defined only in the TS1 encoding.

According to its specification the TS1 encoding contains oldstyle digits as well as the punctuations period and comma. This allows one to typeset dates and other (positive) numbers with oldstyle numerals by simply switching to the TS1 font encoding. Unfortunately, these oldstyle numerals are available only in subencodings 0 and 1, and most fonts only offer subencoding 2 or higher. It is therefore seldom advisable to simply manually switch to TS1 to typeset oldstyle numbers because you might get “■.■.■” or “..” instead of 5.4.1962 as desired.¹

Nevertheless, with the substitution mechanism providing different-looking glyphs based on the situation, it is possible to obtain better results than in earlier days of L^AT_EX, where `\oldstylenums` always used the serified oldstyle numerals available as part of the math fonts. Thus, `\oldstylenums` was changed to make use of this mechanism. If you really want the original definition, use `\legacyoldstylenums`, but note that this can typeset only numbers, not punctuation characters!

	<code>\usepackage[T1]{fontenc}</code>	<code>\usepackage{lmodern}</code>	
	<code>\newcommand\born[1]{\textborn\oldstylenums{#1}}</code>		
I was born *5.4.1962	I was born \born{5.4.1962}		<code>\\</code>
or in sans serif *5.4.1962.	or in \textsf{sans serif \born{5.4.1962}}.		<code>\\</code>
Compare this to 5>4>1962.	Compare this to \legacyoldstylenums{5.4.1962}.		

9-5-11

However, if you want oldstyle numerals and you are not typesetting using Computer or Latin Modern, it is usually better to use the `-OsF` convention supported in many modern fonts or the command `\textfigures` if provided by the package; see Section 10.1.2 on page 6 for details.

Managing missing glyphs

Given that only a few font families implement the full set of the TS1 encoding glyphs, there is the question how missing glyphs should be handled. For this the glyphs from TS1 are split into ten subencodings, numbered 0 to 9, where 0 represents the full set and higher numbers mean that more and more glyphs become unavailable and need to be substituted with glyphs from other fonts. For example, a font family with subencoding 5 (like Gillius) does not support the glyphs labeled 1–5 in Table 9.9 on pages 696 and 697.

If a glyph is unavailable in the current font (based on its subencoding information), then a default from a different font is selected. Of course, if the glyph is “letter-like”, such as №, then it would be bad if the substituted glyph has serifs when the surrounding text is sans serif or vice versa. The mechanism therefore checks if the current font family matches `\rmdefault`, `\sfdefault`, or `\ttdefault` and selects a reasonable matching substitution.²

We demonstrate this in the next example by setting the `\rmdefault` to Gillius (which is of course nonsense because this is a sans serif font) and for comparison

¹These are still substituted glyphs as Lucida does not have them, but they blend reasonably well.

²For fonts that match neither, the default is to use a serified substitute.

`\sfdefault` to Gillius №2, which is a minor variant of the same font. Both have TS1 subencoding 5 so that all five symbols are substituted. In the first case we get serified glyphs and in the second sans serif glyphs as a replacement. While not perfect, the latter is clearly an improvement. To prove that this also works for `\ttdefault` we use Algol Revived as typewriter font, which is also missing these glyphs.¹

Gillius with ©, №, £, ¢, ¶. Roman defaults used — not good. Gillius No2 with ©, №, £, ¢, ¶. Sans defaults used — better! Algol Revived with ©, №, £, ¢, ¶. Typewriter defaults now.	<pre> \renewcommand\rmdefault{GilliusADF-LF} \renewcommand\sfddefault{GilliusADFNoTwo-LF} \renewcommand\ttdefault{AlgolRevived-TLF} \rmfamily Gillius with \textcopyright, \textnumero, \textlira, \textcentoldstyle, \textpilcrow. Roman defaults used --- not good. \sffamily Gillius No2 with \textcopyright, \textnumero, \textlira, \textcentoldstyle, \textpilcrow. Sans defaults used --- better! \ttfamily Algol Revived with \textcopyright, \textnumero, \textlira, \textcentoldstyle, \textpilcrow. Typewriter defaults now. </pre>
---	---

9-5-12

Of course, with mono-spaced fonts the substituted glyphs no longer have the right width and thus break any alignment. In our example this does not matter because Algol Revived is not actually mono-spaced, but in other situations this is something to watch out for.

If such a substitution happens, you get an information line in the `.log` about this. If for important documents you want this more prominent, load the `textcomp` with the option `warn` or `error`. The fonts used for substitution are customizable; for pdf_T_EX they are defined as follows:

```

\newcommand\rmsubstdefault{cmr} \newcommand\sfsbstdefault{cms}
\newcommand\ttsbstdefault{cmtt}
\newcommand\textcompsubstdefault{\rmsubstdefault}

```

where `\textcompsubstdefault` is used when the current font is not one of the document default families.

Unicode engines

In Unicode engines, Latin Modern instead of Computer Modern is used.

While most unavailable glyphs in a TS1 subencoding get substituted by taking the same characters from a different font, this is not the case for the accent commands in the first block of Table 9.9. These accents get replaced by normal accents taken from the T1 encoding (and thus from the same font family). The only exception is `\textcircled`, which is taken from the math fonts if a substitution is necessary.

L^AT_EX already knows the correct TS1 subencoding for more than a hundred font families (including all that are discussed this book). But if you come across fonts that it does not know about (or for some reason assumes that they implement a smaller

¹Actually, newer versions of Algol Revived provide most, but not all, of these glyphs. However, because some glyphs are missing, the TS1 subencoding used by default is supporting none of them.

subset than they actually do), you can inform \LaTeX about the correct font subencoding through a `\DeclareEncodingSubset` declaration.

```
\DeclareEncodingSubset{TS1}{family}{number}
```

The first argument is the *encoding*, but because this concept is implemented only for TS1, it can take only that value. The *family* can take a family name like `Alegreya-LF`, or it can take a partial family name ending in `-*` in which case the subencoding is set for the four families by replacing `-*` with `-LF`, `-TLF`, `-OsF`, and `-TOf`, respectively. Finally, the *number* describes the subencoding and can take a value between 0 (full TS1) and 9 (smallest subset).

To find out which glyphs are available in which subencoding, look at Table 9.9 on pages 696–697. Available are all glyphs shown in black and from the glyphs in blue those marked with a number *higher* than the subencoding. For example, `\textyen` “¥” is always available, `\textflorin` “f” is available in subencodings 0–5, i.e., in most fonts, while `\textpeso` “P” is provided only in those fonts with subencoding 0 or 1, so only in a handful. You can find the subencoding declarations used by \LaTeX in the file `ltxtextcomp.dtx`.

If \LaTeX does not have any information about a font family, it is very cautious and assumes subencoding 9 because this should really be supported by every font that offers any TS1 support. However, it is quite likely that this results in a lot of unnecessary substitutions, because most modern fonts provide subencodings 3–5. If you use fonts not described in this book and you get a lot of visible substitutions, it might be worth determining what exactly is provided and then add an appropriate `\DeclareEncodingSubset` declaration to your document.¹

Altering the subencoding setup for individual glyphs

The split into a set of shrinking subencodings is not giving full justice to the diversity of fonts; i.e., the fonts have been assigned the subencoding for which all glyphs can be produced, but as a result the fonts may well contain one or the other glyph even though its subencoding says differently and you therefore get a substitution.

For example, suppose you typeset in Quattrocento or in Overlock and you happen to need a `\textflorin` and a `\textcurrency` symbol, then you get both from Computer Modern, which looks rather odd (especially the “f”) with either font.

```
\usepackage[rm]{quattrocento} \usepackage{overlock}
Quattrocento: 3\textflorin\ and \textcurrency
```

Quattrocento: 3f and ☐

Overlock: 5f and ☐

```
\sffamily Overlock: 5\textflorin\ and \textcurrency
```

9-5-13

However, both fonts actually have their own florin symbol, so we can do better. One possible solution is to change the symbol default to unconditionally select the

¹It is also possible to change the subencoding assumed for unknown fonts, by using `?` as the family name, e.g., `\DeclareEncodingSubset{TS1}{?}{5}`, which might be a good compromise, but, of course, it may result in some missing glyphs if you are not careful.

glyph from the TS1 encoding, which is what we do in the next example. Of course, it is then up to you to make sure that you use it only with fonts that actually contain the glyph, as what we do means there is no substitution support any longer. This is why we get nothing with Overlock (and no warning or error) if we try the same with `\textcurrency` default!

```
\usepackage[rm]{quattrocento} \usepackage{overlock}
\DeclareTextSymbolDefault{\textflorin}{TS1}
\DeclareTextSymbolDefault{\textcurrency}{TS1}
```

Quattrocento: 3 f and ₤

9-5-14

Overlock: 5 f and oops

\sffamily Overlock: 5 f and \textcurrency oops

If you like to live dangerously, you can also turn off the substitution mechanism completely by loading the `textcomp` package with the options `full` and `force`, but then you should check the final result very carefully for missing glyphs.

In the previous example, some fonts had the desired glyph available, but it was just “unnecessarily” substituted for another. However, what do you do in the case of, say, Overlock and `\textcurrency`? One possibility is to define your own command and make it select a suitable glyph from a different font that fits well enough. In the example below we settled for the glyph from Rosario in the light series, which more or less matches the weight of Overlock.

What the declaration of `\textcurrencysf` does is to switch the font family (inside a group) and then use `\textcurrency` from the TS1 encoding.

```
\usepackage{overlock}
\DeclareTextCommandDefault{\textcurrencysf}
  {{{\fontfamily{Rosario-LF}\fontseries{1}\selectfont
      \UseTextSymbol{TS1}{\textcurrency}}}}
```

9-5-15

Overlook: ₤

Close enough?

\sffamily Overlook: \textcurrencysf \ Close enough?

Instead of defining a default for a new command, we could have overwritten the default for an existing command; for example,

```
\DeclareTextCommandDefault{\textdagger}
  {{{\fontfamily{Almndr-OsF}\selectfont\UseTextSymbol{TS1}{\textdagger}}}}
```

would always typeset the `\textdagger` symbol as † if you like that shape from the Almendra font.¹

Unicode engines

With Unicode engines, this would not have the desired effect because all such symbol commands are directly provided by the TU encoding, and a default definition never applies. Thus, in such engines you need to force the change by

¹For more abstract symbols this approach often gives an acceptable result; in the case of letter-like symbols, the standard substitution mechanism is usually better.

explicitly changing the definition for the TU encoding instead:

```
\DeclareTextCommand{\textdagger}{TU}
    {\fontfamily{Almndr-OsF}\selectfont
     \UseTextSymbol{TS1}{\textdagger}}
```

or by removing it from this encoding via `\UndeclareTextCommand`.

9.5.7 exscale — Scaling large Computer Modern math operators

Normally the font employed for large mathematical symbols is used in only one size. This setup is usually sufficient, because the font includes most of the characters in several different sizes and (L^A)T_EX is specially equipped to automatically choose the symbol that fits best. However, when a document requires a lot of mathematics in large sizes — such as in headings — the selected symbols may come out too small. In this case, you can use the package `exscale`, which provides for math extension fonts in different sizes.

The package is only meant for documents using Computer Modern math fonts or very closely related designs such as Latin Modern because it makes use of the large symbol font of Computer Modern in different design sizes. However, packages providing alternate math font setups often offer this functionality as a package option, usually also named `exscale`.

9.5.8 tracefnt — Tracing the font selection

The package `tracefnt` can be used to detect problems in the font selection system. It supports several options that allow you to customize the amount of information displayed by NFSS on the screen and in the transcript file.

errorshow This option suppresses all warnings and information messages on the terminal; they are written only to the transcript file. However, real errors are shown on the terminal. Because warnings about font substitutions and so on can mean that the final result is incorrect, you should carefully study the transcript file before printing an important publication.

warningshow When this option is specified, warnings and errors are shown on the terminal. This setting gives you the same amount of information as L^AT_EX 2_ε does without the `tracefnt` package loaded.

infoshow This option is the default when you load the `tracefnt` package. Extra information, which is normally written only to the transcript file, is now also displayed on your terminal.

debugshow This option additionally shows information about changes to the text font and the restoration of such fonts at the end of a brace group or the end of an environment. Be careful when you turn on this option because it can produce very large transcript files.

In addition to these “standard tracing” options,¹ the package `tracefont` supports the following options:

pausing This option turns all warning messages into errors to help in the detection of problems in important publications.

loading This option shows the loading of external fonts. However, if the format or document class you use has already loaded some fonts, then these are not shown by this option.

Unicode engines

It is also possible to use `tracefont` with Unicode engines because the `fontspec` package responsible for font loading in these engines uses NFSS underneath its belt.

9.5.9 nfssfont.tex — Displaying 8-bit font tables and samples

The \LaTeX distribution comes with a file called `nfssfont.tex` that can be used to test new 8-bit fonts, produce font tables showing all characters, and perform similar font-related operations.²

This file is an adaption of the program `testfont.tex`, which was originally written by Donald Knuth. When you run this file through \LaTeX , you are asked to enter the name of the font to test. You can answer either by giving the external font name without any extension — such as `cmr10` (Computer Modern Roman 10pt) — if you know it or by giving an empty font name. In the latter case you are asked to provide an NFSS font specification, that is, an encoding name (default `T1`), a font family name (default `cmr`), a font series (default `m`), a font shape (default `n`), and a font size (default 10pt). The package then loads the external font corresponding to that classification.

Next, you are requested to enter a command. Probably the most important one is `\table`, which produces a font chart like the one on page 750. Also interesting is `\text`, which produces a longer text sample. To switch to a new test font, type `\init`; to finish the test, type `\bye` or `\stop`. To learn about all the other possible tests (at the moment basically still tailored for the OT1 encoding), type `\help`. The default action is `\table\bye` because this is what is usually wanted.

9.6 fontspec — Font selection for Unicode engines

Unicode engines

One important difference between $\text{pdf}\text{\LaTeX}$ and Unicode engines is the way fonts are loaded and accessed. Up to this point we have covered the interfaces that are essentially common to all engines (with the exception of the `fontenc` package). In this section we describe the `fontspec` package, which should be

¹ It is suggested that package writers who support tracing of their packages use these four standard names if applicable.

² How to produce font tables for larger fonts is discussed in Section 9.6.7 on page 728.

used to load and access fonts when using \XeTeX or \LuaTeX . Thus, technically all of this section should be presented inside a gray box because it applies only to Unicode engines, but to prevent eye trouble with our readers, the rest of this section does not show this gray background.

In \pdfTeX , fonts can be specified simply through calls to \fontfamily or through support packages that do those calls on behalf of the user. In Unicode engines this interface does not work because fonts in Unicode encoding (TU) usually do not have any supporting \.fd files and so \fontfamily would not know how to load font shape declarations and alter the internal NFSS tables to access the requested fonts.

This is the price of the fact that with Unicode engines it is essentially possible to use any OpenType or TrueType font available on your computer without the need to first provide font metric files (\.tfm) for \TeX .

At the same time, directly using the low-level font loading facilities of the Unicode engines is not practical either, and so Will Robertson with contributions by Khaled Hosny, Philipp Gesang, and others developed the `fontspec` package that abstracts this loading process and provides a fairly simple and flexible interface to combine it with the powers of NFSS.

9.6.1 Setting up the main document font families

At its core, `fontspec` provides three declarations to set up three font families needed in most documents: a serif family, a sans serif family, and a typewriter family that then can be accessed through the usual NFSS commands, i.e., $\text{\texttt{rm}}$, $\text{\texttt{sf}}$, and $\text{\texttt{tt}}$ or the corresponding declarative forms.

```
\setmainfont{family}[feature-list]
\setsansfont{family}[feature-list]
\setmonofont{family}[feature-list]
```

These declarations set up the document font families for the main fonts (serif), the sans fonts, and the typewriter fonts. In contrast to the usual NFSS practice of specifying some internal font family name, the *family* argument here expects the external name of an OpenType or TrueType font family. There are basically two ways to specify the *family*, either by “family name” or by “font file name”. Both have their advantages and disadvantages; personally I prefer the family name approach because I think this is more readable and you do not have to deal with different file names for different font faces — all font tables in Chapter 10 provide the necessary names in this form.¹ The *feature-list* allows you to request specific font features or alter the setup in other aspects. This is discussed below.

As an introductory example, consider typesetting a document in Optima, which is available as a system font on Macintosh computers. In that case, all you have to do is to specify the family name as an argument to \setmainfont . This automatically takes

¹However, when using \XeTeX , explicit font file names are usually better.

care of defining italics, boldface, bold italic shapes, and corresponding small caps shapes (if available) so that basic font selection commands are immediately available.¹

This **text** is typeset in the *system font* Optima. Sans Serif and Typewriter still default to Latin Modern Sans and Typewriter.

9-6-1

```
\usepackage{fontspec} \setmainfont{Optima}
This \textbf{text} is typeset in the \emph{system font}
Optima. \textsf{Sans Serif} and \texttt{Typewriter}
still default to Latin Modern Sans and Typewriter.
```

For system fonts, that is, fonts that are stored in standard font locations, e.g., such as ~/Library/Fonts on macOS, or C:\Windows\Fonts on Windows, the above approach works in all T_EX engines. However, if we use a font family that is stored within the T_EX distribution tree (which is usually the case for the families discussed in this book), then this works with LuaT_EX but unfortunately not on all operating systems with X_YT_EX. Thus, if we replace Optima with, say, Alegreya in the previous example, we get the desired result with LuaT_EX, but when using X_YT_EX on a Mac or on a Linux system, we see something like

```
kpathsea: Running mktexmf Alegreya

! I can't find file 'Alegreya'.
<*> ...ljfour; mag:=1; nonstopmode; input Alegreya
```

because the fonts are not found and X_YT_EX unsuccessfully tries to generate them from some nonexistent METAFONT sources. If that happens, i.e., if you are using X_YT_EX and you want to use such a family, then the solution is to either add the font folder of your T_EX system to your fontconfig configuration (check the documentation of your T_EX system for how to do it) or to use the “by file name” approach and specify the actual font files in the declaration.

The former solves the problem for your own setup, but it is nonportable; i.e., your documents may not work elsewhere. The latter works everywhere, but is more work and involves two steps: first finding the names of the relevant font files and then specifying how they are mapped to italics, bold, etc., because that must be now done manually. For finding the real font names there are different possibilities; here is one that uses luaotfload-tool:

```
luaotfload-tool --list="familyname:alegreya" \
                --fields="location,plainname,basename"
```

You pass it the font family name but with all spaces removed (if any) and in only lowercase letters. For example, for “URW Classico” from Table 10.60 on page II 72 you would specify urwclassico instead of alegraya. In our case we get the following list as output:

```
alegreya texmf Alegreya Bold           Alegreya-Bold.otf
alegreya texmf Alegreya Black Italic  Alegreya-BlackItalic.otf
alegreya texmf Alegreya Medium Italic Alegreya-MediumItalic.otf
```

¹This font has no small capitals.

```

alegreya texmf Alegreya ExtraBold Italic Alegreya-ExtraBoldItalic.otf
alegreya texmf Alegreya Italic Alegreya-Italic.otf
alegreya texmf Alegreya ExtraBold Alegreya-ExtraBold.otf
alegreya texmf Alegreya Regular Alegreya-Regular.otf
alegreya texmf Alegreya Medium Alegreya-Medium.otf
alegreya texmf Alegreya Black Alegreya-Black.otf
alegreya texmf Alegreya Bold Italic Alegreya-BoldItalic.otf

```

Alternatively, you can use Herbert Voß's `luafindfont` program, which is essentially a simple-to-use frontend to the database of `luaotfload-tool`. You pass it a string as its argument and it finds you all fonts that contain this string as part of their symbolic name (the font family name without spaces and all lowercased), e.g.,

```
luafindfont -m 40 alegreya
```

In contrast to `luaotfload-tool`, this finds 48 fonts, because the string is also matching other names such as `alegreyasans`. With `-m` you can limit the number of characters shown in the path, which we did here to fit it into the book; normally you would not use it.

Nr.	Fontname	Symbolic Name	Path
1.	Alegreya-Black.otf	alegreya	/usr/local/texlive/2023/te...a/alegreya/
2.	Alegreya-BlackItalic.otf	alegreya	/usr/local/texlive/2023/te...a/alegreya/
...			
11.	AlegreyaSans-Black.otf	alegreyasans	/usr/local/texlive/2023/te...a/alegreya/
12.	AlegreyaSans-BlackItalic.otf	alegreyasans	/usr/local/texlive/2023/te...a/alegreya/
...			
13.	AlegreyaSans-Bold.otf	alegreyasans	/usr/local/texlive/2023/te...a/alegreya/
14.	AlegreyaSans-BoldItalic.otf	alegreyasans	/usr/local/texlive/2023/te...a/alegreya/
...			
25.	AlegreyaSansSC-Black.otf	alegreyasanssc	/usr/local/texlive/2023/te...a/alegreya/
26.	AlegreyaSansSC-BlackItalic.otf	alegreyasanssc	/usr/local/texlive/2023/te...a/alegreya/
...			
39.	AlegreyaSC-Black.otf	alegreyasans	/usr/local/texlive/2023/te...a/alegreya/
40.	AlegreyaSC-BlackItalic.otf	alegreyasans	/usr/local/texlive/2023/te...a/alegreya/
...			
48.	AlegreyaSC-Regular.otf	alegreyasans	/usr/local/texlive/2023/te...a/alegreya/

Interesting further features of `luafindfont` are the options `-i` or `-o` followed by the line number of the font you are interested in, e.g.,

```
luafindfont alegreya -o 2
```

which gives you the `otfinfo` output for the Black Italic Alegreya font without the need to pass the full path to the program:

```

Run otfinfo:2
Family:           Alegreya Black
Subfamily:        Italic
Full name:         Alegreya Black Italic
PostScript name:  Alegreya-BlackItalic
Preferred family:  Alegreya

```

```

Preferred subfamily: Black Italic
Version:             Version 2.008;PS 002.008;hotconv 1.0.88;makeotf.lib2.5.64775
Unique ID:           2.008;HT ;Alegreya-BlackItalic
Designer:           Juan Pablo del Peral

```

As you can see, the Alegreya family has ten different font faces, so we have to select those that we want to use. The upright face goes into the mandatory argument, and the others have to be specified in key/value syntax in the optional argument using the keys `ItalicFont`, `BoldFont`, and `BoldItalicFont`.

```

\usepackage{fontspec}
\setmainfont{Alegreya-Regular.otf}
[ ItalicFont      = Alegreya-Italic.otf,
  BoldFont        = Alegreya-Bold.otf,
  BoldItalicFont  = Alegreya-BoldItalic.otf ]

```

This **text** is typeset in the
family Alegreya. It supports
bold italic and SMALL CAPS.

This `\textbf{text}` is typeset in the `\emph{family}` Alegreya. It
supports `\textbf{\itshape bold italic}` and `\textsc{Small Caps}`.

The above gives us the same result as `\setmainfont{Alegreya}` (with Lua \TeX) but works in both engines. However, the file name syntax is more powerful because we can select other faces at will. For example, we can use the Medium and the ExtraBold (or even the Black) fonts so that everything comes out slightly darker. Below we show that setup. That example also shows an alternative specification syntax, where the common part of the name is placed in the mandatory argument, which is then referred to in the key/values by using a `*`. If we do this, we have to additionally use the key `UprightFont` because the mandatory argument no longer contains the font for the upright face.

```

\usepackage{fontspec}
\setmainfont{Alegreya}
[ UprightFont      = *-Medium.otf,
  ItalicFont       = *-MediumItalic.otf,
  BoldFont         = *-ExtraBold.otf,
  BoldItalicFont   = *-ExtraBoldItalic.otf]

```

This **text** is typeset in the
family Alegreya. It supports
bold italic and SMALL CAPS.

This `\textbf{text}` is typeset in the `\emph{family}` Alegreya. It
supports `\textbf{\itshape bold italic}` and `\textsc{Small Caps}`.

Small capitals are a bit special, because in modern fonts they are usually not provided in a separate font files but instead accessed through OpenType font features. This explains why there was no need for us to set them up explicitly. When we provide

SMALL CAPITALS

the fonts for upright, italics, or bold, then `fontspec` queries the font resources, and if they support small capitals as a feature, it automatically sets up the corresponding shape as well.

However, sometimes the small capitals are supplied in separate font files, in which case this automatism cannot work. If this is the case, one can set up this shape by supplying the font file with the key `SmallCapsFont`. Details on this approach are given in the `fontspec` package documentation [172].

*Slanted or oblique
fonts*

Besides italics and bold, fonts sometimes also contain oblique/slanted faces. The latter are not automatically set up. Instead, we have to explicitly specify what font should be selected for that shape with the keys `SlantedFont` and `BoldSlantedFont`. Without these keys `\slshape` and `\textsl` are aliased to italics. Below is an example with `XCharter`:

```

\usepackage{fontspec}
\setmainfont{XCharter}[SlantedFont = XCharter-Slanted.otf,
                        BoldSlantedFont = XCharter-BoldSlanted.otf ]
Italics versus slanted.
SOME FACES OF SMALL \textit{Italics} versus \textsl{slanted}. \par
CAPITALS.           \textsc{Some \textit{Faces} of \textbf{Small \slshape Capitals}}.

```

9-6-4

Swash fonts

In a similar manner you can set up a swash font or a bold swash font explicitly by using `SwashFont` or `BoldSwashFont`, respectively. However, because of the fact that swash letters are typically activated through a style feature (see below) in OpenType fonts, you also have to specify `SwashFeatures={Style=Swash}` to make it work.

The *feature-list* that one needs to provide in the optional argument of the `\set...font` declarations can sometimes get rather lengthy, and to avoid that, this then has to be repeated in every document, and `fontspec` offers some help. When a *family* is set up, the package checks if the file *family.fontspec* can be found and if so loads it first. More precisely, the *family* argument is first stripped of any spaces and any font file extension (in case the “by file name” approach is used). For example, when setting up Noto Sans, it would look for `NotoSans.fontspec`, and in Example 9-6-2 it tried to find `Alegreya-Regular.fontspec`.

Such a file is supposed to contain a `\defaultfontfeatures` declaration, listing key/value pairs that should be applied, for example,

```

\defaultfontfeatures[XCharter]{ Extension = .otf ,
    UprightFont = XCharter-Roman,    BoldFont      = XCharter-Bold,
    ItalicFont  = XCharter-Italic,   BoldItalicFont = XCharter-BoldItalic,
    SlantedFont = XCharter-Slanted,  BoldSlantedFont = XCharter-BoldSlanted,
    SmallCapsFeatures = {Letters=SmallCaps} }

```

If such a `.fontspec` file exists, but you do not want to see it applied for some reason, specify the key `IgnoreFontspecFile` in the *feature-list*. For more details on this interface consult [172]. For `XCharter`, a `XCharter.fontenc` file exists as part of the \LaTeX font support and so we could have omitted the optional argument in Example 9-6-4 above and achieved the same result.

9.6.2 Setting up additional font families

Most of the time it is enough to set up the fonts for `\rmfamily`, `\sffamily`, and `\ttfamily` with the declarations discussed above. However, sometimes one needs additional fonts for special cases. For example, you might want to use a specially condensed font for marginal notes or you want to define heading commands that use a different font family from the document body font and not just a bolder version of that. For such purposes you can define named font commands that work just like `\rmfamily` but select the desired family instead.

```
\newfontfamily{cmd}{family}[feature-list]
```

The `\newfontfamily` declaration defines a new font family (like `\rmfamily`) and makes it available through *cmd*. If *cmd* is already defined, you receive an error message. To overwrite an existing definition use `\renewfontfamily` instead. There also exist `\providefontfamily` (provide only if undefined) and `\setfontfamily` (always define without checking). The next example sets up `\headfamily` as a special family and uses it in a `\titlesec` declaration.

1 On Reason

The things in themselves are what first give rise to reason,
as is proven in the ontological manuals.

```
\usepackage{kantlipsum,fontspec}
\setmainfont{GaramondNo8}
\newfontfamily{\headfamily}{Bitter}
```

1.1 Considerations

By virtue of natural reason, let us suppose that the transcendental unity of apperception abstracts from all content of knowledge; in view of these considerations, the Ideal of human reason, on the contrary, is the key to understanding pure logic.

```
\usepackage[compact]{titlesec}
\titleformat*{\section}{\headfamily}
\titleformat*{\subsection}{\headfamily}

\section{On Reason}           \kant[6][1]
\subsection{Considerations} \kant[6][2]
```

9-6-5

If you also wish to have a `\texthead` command available for the new family, use `\DeclareTextFontCommand` in addition:

```
\DeclareTextFontCommand{\texthead}{\headfamily}
```

```
\fontspec{family}[feature-list]
```

The `\fontspec` command sets up an unnamed family for direct use, which is therefore available only at the point of declaration. This is mainly useful when testing a font (or in the examples of this book) where it saves a few keystrokes but seldom in normal documents.

9.6.3 Setting up a single font face

Sometimes access to a single font face is wanted and there is no need to set up the whole family with all its different faces. In that case you might prefer `\newfontface` over `\newfontfamily` because that saves processing time and resources.

```
\newfontface{cmd}{font}[feature-list]
```

This defines *cmd* to select the *font* loaded with *feature-list*. If you specify a family name in the *font* argument, the base face is selected. Also supported are `\renew...`, `\provide...`, and `\set...` variants of the declaration.

9.6.4 Interfacing with core NFSS commands

As mentioned before, the interface to NFSS is by default partly hidden, and all necessary setups are done behind the scenes by the `fontspec` declarations. As a result, it is possible to use the high-level NFSS commands such as `\textsf`, `\bfseries`, `\itshape`, etc., but it is not possible to use `\fontfamily` (because the family name internally defined by `fontspec` is not known to you) nor can you say `\fontseries{c}` to request a condensed series because series values other than *m* and *b* are not set up automatically, unless you have a special `.fontspec` file for the font family.

There are, however, ways to provide the necessary information as part of the *feature-list* argument in the `fontspec` declarations discussed thus far.

To explicitly name the font family, use the key `NFSSFfamily`. A possible use case for this is shown in the next example, where we explicitly set the NFSS family name and then pass it to `fancyvrb`. Usually the high-level commands or newly defined ones, like `\fvrbfamily`, for changing the family are enough, so this is seldom needed.

```

\usepackage{fancyvrb,fontspec}
\newfontfamily\fvrbfamily{AlgolRevived}
[NFSSFfamily=AlgolR]

\begin{Verbatim*}[fontfamily=AlgolR]
... while it works in T1: \sum_{i=1}^n
UTF-8 char test: äöüß æ £ $ £ » „ «
\end{Verbatim*}

```

9-6-6

More interesting are cases where a font family has a larger selection of weights or running lengths and you want to access some of them. Because `fontspec` only sets up the medium and the bold series, we need to provide anything else through one or more `FontFace` key settings. It supports the following two syntax variants:

```
FontFace={series}{shape}{font}
```

or

```
FontFace={series}{shape}{Font=font, feature-list}
```

The *series* and *shape* are the NFSS axes under which we want to access the *font* face. In the simple form we only supply a *font* name, but often we want to also enable or disable some features. In that case we have to use a feature list in the third argument and supply the *font* through the key `Font`. This is what we do in the next example where we define support for the swash shapes offered by EB Garamond. After defining what font `sw` and `scsw` should switch to, we can use the standard commands `\textsw`

and `\swshape`. For both declarations we need the *feature-list* syntax variant, because we have to enable special font features (discussed later).

```

\usepackage{fontspec}
\setmainfont{EB Garamond}
[ FontFace={m}{sw} {Font=EBGaramond-Italic.otf,Style=Swash},
  FontFace={m}{scsw}{Font=EBGaramond-Italic.otf,
                    Letters=SmallCaps,Style=Swash} ]
Show A Few EB Garamond
Italic Letters: SPQR.
Show A Few EB Garamond
Swash Letters: SPQR.
\textit{Show A Few EB Garamond Italic Letters: \textsc{Spqr}}.
\textsw{Show A Few EB Garamond Swash Letters: \textsc{Spqr}}.

```

9-6-7

A slightly more concise way of achieving the same effect in this case would have been to use the `SwashFont` and `SwashFeatures` keys as follows:

```

\setmainfont{EB Garamond}[ SwashFont=EBGaramond-Italic.otf,
                          SwashFeatures={Style=Swash} ]

```

This too would set up the small caps variants implicitly.

9.6.5 Altering the look and feel of fonts

The interfaces of the `fontspec` package allow loading fonts with specific features enabled by specifying those in the form of key/value pairs. This can be done in the optional *feature-list* argument of any of the declarations. These features are then applied when loading and setting up the font family, e.g., the declaration

```
\setmainfont{Alegreya}[Numbers = {OldStyle, Proportional}]
```

asks for loading the *Alegreya* fonts with proportional oldstyle figures, i.e., different digits may have different widths, depending on their shape. That setting may be right for numbers in normal text, but if we typeset a table in which numbers should align for ease of reading, we may want to temporarily change from *Proportional* to *Monospaced*. It is therefore also necessary to alter or apply features only occasionally within the document.

```
\addfontfeature{feature}    \addfontfeatures{feature-list}
```

These commands¹ apply the given *feature* or *feature-list* to the current font family (and all its different faces including those added through `FontFace`). Already enabled features are kept unless they conflict with the newly requested feature(s). This is a local change, so it remains in force until the end of the current group or environment.

For example, requesting `Numbers=Monospaced` would preserve *OldStyle* but overwrite *Proportional*, because the two are mutually exclusive. Of course, when

¹`\addfontfeature` is just an alias for `\addfontfeatures`, so technically both accept a *feature-list*.

using such commands more often, it is usually better to provide your own little commands for this, e.g.,

```
\newcommand\nummono{\addfontfeature{Numbers=Monospaced}}
\newcommand\tabularnums[1]{\{\nummono #1}}
```

Note the extra set of braces in `\tabularnums` to confine the feature change to `#1`.

Using generally available font features

Some font features that can be adjusted through the `fontspec` interfaces are available with any font family; others may be implemented only by some fonts.

Scaling fonts If different font families are used together, it is often the case that one of them needs to be slightly scaled up or down to match the height of the other. For this `fontspec` offers the key `Scale`. It takes either a numeric value as the scale factor, e.g., 1.05, or the values `MatchLowercase` or `MatchUppercase`, matching the x-height or the capital height of the main (`\familydefault`) family.

<p>A sample text mixing Sans, Typewriter, and Roman in one sentence.</p>	<pre>\usepackage{fontspec} \setmainfont{TeX Gyre Termes} % Times \setsansfont{TeX Gyre Heros}[Scale=MatchLowercase] % Helvetica \setmonofont{Latin Modern Mono}[Scale=MatchLowercase] % LM Mono A sample text \textsf{mixing Sans}, \texttt{Typewriter}, and Roman in one sentence.</pre>
--	---

9-6-8

Successive usages of `Scale` for the same family overwrite each other. If you want to accumulate scale factors for fine-tuning, use `ScaleAgain` instead.

Coloring fonts At a fairly low level, fonts can be colored using the key `Color`. This works even if no color support for \LaTeX has been loaded as it is interacting directly with the font resource, i.e., coloring the glyphs. By default the color has to be given as a triplet of two-digit hexadecimal values, e.g., `FF0000` for red, with optionally a fourth value for the transparency (where `00` is completely transparent and `FF` is opaque). If you load `xcolor` (but not `color`) you can alternatively use “named” colors as values and then describe the transparency through the key `Opacity` (values between 0 and 1).

If a font is colored in this way, then \LaTeX ’s color commands no longer influence that particular font at all, as can be seen in the last input line of the example.

Text in black.
Text still in blue
and not red!

```
\usepackage{xcolor,fontspec} \setmainfont{EB Garamond}
\Large\bfseries
\makebox[0pt][l]{\addfontfeature{Color=black,Opacity=0.5}%
Text in black.}%
\hspace{1pt}\addfontfeature{Color=blue,Opacity=0.7}Text in blue.\
\textcolor{red}{Text still in blue and not red!}
```

9-6-9

Other generally available features There are a number of other keys that can be used with any font, but they are too special to discuss in detail, so we only list them. Refer to [172] for details and examples if you think you need any of them.

WordSpace allows you to alter the width, stretch, and shrink of a space character; PunctuationSpace alters the extra space after punctuation characters; and with LetterSpace you can add some extra kerns between glyphs for tracking purposes (this is how microtype manages letterspacing in such fonts). There is also HyphenChar=None that allows you to suppress hyphenation in that font.¹

Space handling and hyphenation

Some font families offer separate font files for different sizes, and those can be explicitly selected to be used for certain size ranges using a combination of SizeFeatures, Size, and OpticalSize.

Optical size support

There are even possibilities to artificially transform a given font by mechanically boldening it with FakeBold or tilting with FakeSlant or stretching or compressing it with FakeStretch, but the results are usually noticeably inferior to properly designed fonts and should therefore be used with extreme care or not at all.

Producing artificial series values (bold and stretch)

Specifying OpenType font features

OpenType fonts often implement variants through a set of named features. These feature names consist of four letters, such as smcp (small capitals) or ss02 (stylistic set 2), and there are more than a hundred such feature tags defined; see [126] for a nice (but not even complete) overview together with explanations for each feature.

These short names are naturally rather cryptic, so fontspec offers a more readable interface to many of them. We introduce the more important ones through examples, but given the number of possibilities, this is obviously only scratching the surface. More details can be found in the fontspec documentation [172], which has more than thirty pages devoted to that topic.

Besides knowing how to enable certain font features, a big question is how we can find out what features are offered by a given font file. One possible way is to use the program `otfinfo` in a terminal window. For example, to get a list of all features implemented by XCharter-Roman we could run

```
otfinfo -f 'kpsewhich XCharter-Roman.otf'
```

on Linux or MacOS,² which would then respond with the following list:

c2sc	Small Capitals From Capitals	mkmk	Mark to Mark Positioning
case	Case-Sensitive Forms	numr	Numerators
cpSP	Capital Spacing	onum	Oldstyle Figures
cv01	Character Variants 1	smcp	Small Capitals
dnom	Denominators	ss01	Stylistic Set 1
kern	Kerning	ss02	Stylistic Set 2
liga	Standard Ligatures	subs	Subscript
lnum	Lining Figures	supS	Superscript
mark	Mark Positioning	tnum	Tabular Figures

¹In Xe_{La}T_EX it can also be used to explicitly define a different hyphenation character.

²On Windows use `for /F %i in ('kpsewhich XCharter-Roman.otf') do otfinfo -f %i` instead.

Value	feature	Value	feature
Lining	lnum	OldStyle	onum
Proportional	pnum	Monospaced	tnum
SlashedZero	zero	ResetAll	—

Uppercase and Lowercase can be used as synonyms for Lining and OldStyle.
Individual features can be turned off by appending Off to the name.

Table 9.10: Values accepted by the Numbers key

As you see, this list comes with a short explanation for each feature so that one can often already guess what a feature does. For example, seeing `smcp` explains why `fontspec` was able to automatically set up the Small Caps shapes in Example 9-6-4. For others it may not be so clear, and there the explanations in [126] and our discussions below may help. We now discuss a selection of these features and how to specify them in the *feature-list* arguments.

Figure style features An important variation supported by many font families is alternate styles for digits. For this, `fontspec` offers the key `Numbers` that we already used without much explanation earlier. Allowed values and the corresponding feature tags are given in Table 9.10.

The next example shows the different combinations using `Cochineal` as the sample family. How the keys behave in relation to each other is defined by the font resource. Here the keys are orthogonal as expected, but in others setting `OldStyle` might automatically change to `Proportional`, because the font does not offer monospaced, oldstyle figures. In many fonts `SlashedZero` (if available) produces a fixed (lining) glyph, so it does not work well in combination with `OldStyle`. Due to the use of `ResetAll` we get the font defaults in the last example line, which for this font is lining, monospaced.

Also note the use of extra braces when we supply several values to one key. They are needed to hide the comma, which would otherwise be misinterpreted.

```
\usepackage{fontspec}
\setmainfont{Cochineal}[Numbers = {OldStyle,Proportional}]

Digits: 0123456789 \noindent Digits: 0123456789\\
Digits: 0123456789 \addfontfeature{Numbers={Monospaced,SlashedZero}}Digits: 0123456789\\
Digits: 0123456789 \addfontfeature{Numbers=Lining} Digits: 0123456789\\
Digits: 0123456789 \addfontfeature{Numbers=Proportional} Digits: 0123456789\\
Digits: 0123456789 \addfontfeature{Numbers=ResetAll} Digits: 0123456789
```

9-6-10

If you look through the font tables in Chapter 10, you can easily identify if lining and oldstyle figures are supported and whether they have a proportional and/or a

<i>Value</i>	<i>feature</i>	<i>Value</i>	<i>feature</i>
SmallCaps	smcp	UppercaseSmallCaps	c2sc
PetiteCaps	pcap	UppercasePetiteCaps	c2pc
Unicase	unic		

Individual features can be turned off by appending Off to the name.

Table 9.11: Values accepted by the Letters key

monospaced variant (this is implicitly encoded in the suffixes -LF, -TLF, -OsF, and -TosF; see page →II 6 for details).

For oldstyle numbers, standard L^AT_EX has a fairly complicated definition to cater for the fact that in its default fonts, the oldstyle numerals are stored in a strange place (i.e., inside the math fonts) and for other fonts need to be fetched from TS1-encoded files (if available). In Unicode engines using OpenType fonts this is simpler, because all that is required is enabling the OldStyle feature. So fontspec changes the definition of `\oldstylenums` to do just that and additionally adds a `\liningnums` command to provide a simple way to get lining numerals if oldstyle numerals are used by default.

`\oldstylenums`
simplified

Letter case features Earlier we mentioned that small capitals are automatically set up by fontspec if available as an OpenType feature in the font. However, there are in fact several features related to small capitals, and sometimes you may want to choose something different from the default. The features are accessed through the key `Letters`, and its possible values are given in Table 9.11. The most common one is `SmallCaps` (`smcp`), which is what fontspec looks for when trying to automatically set up small capitals. It affects the lowercase letters and changes them to become small capitals. `PetiteCaps` (`pcap`) is similar but uses even smaller capitals in place of the lowercase letters.

The features `UppercaseSmallCaps` (`c2sc`) and `UppercasePetiteCaps` (`c2pc`) on the other hand alter only uppercase letters and replace them with smaller versions. Thus, it is possible to combine a value from the first group with one from the second, which is what we do in Example 9-6-11 on the next page.

However, we do not want the `Letters` key to affect the whole family; we want to apply it only when the user requests small capitals via `\textsc` or `\scshape`. This is why we do not use it directly but supply it as a value to `SmallCapsFeatures`. This key expects a *feature-list* applicable only when `\textsc` is requested.¹ In the second half of the example we then show what happens if we supply the `Letters` key at the top level, i.e., to the whole family. Also note the size difference between small capitals and petite capitals.

¹ Similar keys exist to supply *feature-lists* applicable to other font faces, e.g., `ItalicFeatures`, `BoldFeatures`, and so forth; for further details see [172].

	<pre>\usepackage{fontspec} \setmainfont{EB Garamond} [SmallCapsFeatures = {Letters={UppercaseSmallCaps,PetiteCaps}}] \raggedright Different \textsc{\textit{Faces} Of \textbf{Small \itshape Capitals} Followed} By \textit{Further} Text. BUT NOW <i>EVERYTHING</i> \addfontfeature{Letters = SmallCaps} USES SMALL CAPITALS! But Now \textit{Everything} Uses \textbf{Small \itshape Capitals}!</pre>	9-6-11
--	--	--------

The Unicase (unic) value enables a rather strange feature that maps all upper and lowercase letters to a mixture of small capitals and lowercase letters so you end up getting something like

WEIRD MAPPING AHEAD

Because none of the free fonts discussed in this book supports this feature, the above is an artificially made up example.

Vertical positioning features For writing text such as 1st, 2nd, 3rd or 1_a, 1_b, etc., L^AT_EX offers the generic commands \textsuperscript and \textsubscript that raise or lower their argument and select a smaller font size to typeset it.

This gives usable results with any font, although due to using a smaller version of the same font, the glyphs come out somewhat too light, and the vertical positioning may not be perfect either. However, modern fonts often have especially designed glyphs for this purpose that do not have these defects. The next example shows the differences. There we define two commands to typeset superior and inferior glyphs. The key to select these glyphs is VerticalPosition, and the possible values for it are given in Table 9.12 on the facing page. Also compare this with Example 10-1-1 on page →II 9 showing how to access such glyphs when using pdfT_EX.

	<pre>\usepackage{fontspec} \setmainfont{Alegreya} \newcommand\textsu[1]{\addfontfeature{VerticalPosition=Superior}#1} \newcommand\textin[1]{\addfontfeature{VerticalPosition=Inferior}#1} Catch\textsubscript{22} in Room13% inferior quality Catch\textin{22} in Room\textsu{13} % much better!</pre>	9-6-12
--	--	--------

Obviously, such a feature should only be turned on locally. It is also important to note that the characters affected differ from font family to font family. Sometimes both digits and letters are available raised and lowered, but often only a few letters are raised or only the digits are available in inferior positions.

The next example exhibits the results of the values Superior (raising digits and [some] letters), Ordinal (slightly less raised, often only the letters “abdeilmnorst”), Inferior (usually only digits), and ScientificInferior (compared to Inferior

<i>Value</i>	<i>feature</i>	<i>Value</i>	<i>feature</i>
Superior	sup	Inferior	sub
Ordinal	ordn	ScientificInferior	sinf
Numerator	numr	Denominator	dnom
ResetAll	—		

Individual features can be turned off by appending Off to the name.

Table 9.12: Values accepted by the VerticalPosition key

further below the baseline). Depending on the font family, some of the features may not be available or affect a larger or smaller set of glyphs.

```

X1234 strd      (Superior)  \usepackage{fontspec} \setmainfont{Alegreya}
X1234 strd      (Ordinal)    \newcommand\test[1]
X1234 strd      (Inferior)    {X{\addfontfeature{VerticalPosition=#1}1234 strd}
X1234 strd      (ScientificInferior) \hfill (\texttt{\footnotesize#1})\par}
X1234 strd      (ResetAll)    \test{Superior} \test{Ordinal} \test{Inferior}
X1234 strd      (ResetAll)    \test{ScientificInferior} \test{ResetAll}

```

9-6-13

If you look through the font tables in Chapter 10, you can see whether a font family supports a superior style (-Sup) or an inferior style (-Inf). Usually that means Superior and Inferior are available, but sometimes only ScientificInferior is provided as a feature.

As an alternative, you may want to check out the small realscripts package by Will Robertson, which redefines `\textsuperscript` and `\textsubscript` to use the above font features if available. The original L^AT_EX meaning remains available as starred forms of the command. To simplify typesetting superscripts on top of subscripts the package also defines `\textsubsuperscript[pos]{sub}{super}`. If necessary, the distance between the two can be adjusted by altering the length parameter `\subsupersep`.

Using the realscripts package for script characters

The values Numerator and Denominator, if available, affect only digits and are meant for the special case of slashed fractions. Below we show their results in case of different Noto families. For the typewriter font we have specified the font by name in order to get a condensed font selected in the example.

```

\usepackage{fontspec} \setmainfont{Noto Serif}
\setsansfont{Noto Sans} \setmonofont{NotoSansMono-Condensed.ttf}
\newcommand\txtfrac[2]{\addfontfeature{VerticalPosition=Numerator}#1}%
/\addfontfeature{VerticalPosition=Denominator}#2}%
1/2 47/11 1/1000 \txtfrac{1}{2} \txtfrac{47}{11} \txtfrac{1}{1000} \par
1/2 47/11 1/1000 \sffamily \txtfrac{1}{2} \txtfrac{47}{11} \txtfrac{1}{1000} \par
1/2 47/11 1/1000 \ttfamily \txtfrac{1}{2} \txtfrac{47}{11} \txtfrac{1}{1000}

```

^bOn by default for fonts set up with `\setmainfont` and `\setsansfont`.
Individual features can be turned off by appending `Off` to the name.

Table 9.13: Values accepted by the Ligatures key

Instead of using `VerticalPosition` to build your fractions, you can try the key `Fractions` (`frac`), which is implemented in many fonts and automatically builds fractions when it sees a slash (/) in the source. Note, however, that this may make it impossible to use the slash for normal text or mixed fractions. What also can happen is that only fractions precomposed in the font work, such as with IBM Plex Mono.

```
\usepackage{fontspec} \setmainfont{Erewhon}[Fractions=On]
\setsansfont{Lato}[Fractions=On]
\setmonofont{IBM Plex Mono}[Fractions=On]

\ttfamily 1/2 2/3 47/11 1/1000 a/b 1/n
```

9-6-15

Ligature features Nearly every font defines some sets of ligatures, i.e., characters that if appearing in succession are not typeset one after the other but get replaced by a new glyph. In \TeX this happens automatically behind the scenes; e.g., if you enter `ffi`, you get “ffi” instead of “ffi”, etc.

In pdf \TeX , due to the limitation of glyphs per font, only f-ligatures and a few special ligatures, such as ! ‘ generating “,”, are available, but with OpenType fonts there are not any limits and so many modern fonts provide a much richer set of ligatures. However, only some of them are enabled by default; the others need to be activated through the key `Ligatures`. Possible values are listed in Table 9.13.

If given the value `TeX`, the special ligatures traditionally provided by \TeX are enabled, e.g., `--` producing an en-dash and `---` an em-dash. This is automatically done by `fontspec` if you set up the main font family or the sans family. For any other font you load you need to enable them yourself. This is not a feature of the OpenType fonts (so does not correspond to a feature tag) but is handled by the code loading the font in \TeX .

In addition, OpenType fonts may have up to five feature tags that define ligature sets. The value `Required` (`rlig`) enables ligatures that are required by the script for

correct typesetting. Latin script does not really have any required ligatures, which is why the fonts we show in this book normally do not implement this feature. However, when typesetting, for example, Arabic, that set is nonempty. Being “required”, it is enabled by default.

Also enabled by default are the Common ligatures (liga), i.e., those that the designer of the font thought should be always used. This set typically covers f-ligatures but sometimes also others. For example, in the Accanthis family the less common ligatures “fj” and “ft” are part of the set, but they are not ligatures in Lucida Bright — the family used for this book. For some reason Accanthis also has required ligatures (a questionable decision), but it allows us to show all three sets here.

“ - — ¡ ¿ ”	(TeX)	
æ Æ œ Œ	(required)	<code>\usepackage{fontspec} \setmainfont{Accanthis Adf Std No3}</code>
fi ffi fl ffl fj ffj ft	(common)	<code>‘ ‘ -- --- ! ‘ ? ‘ ’ ’ \hfill (TeX) \ \ ae Ae oe Oe \hfill (required)</code>
“ -- --- ! ‘ ? ‘ ”		<code>\ \ fi ffi fl ffl fj ffj ft (common) \ \</code>
ae Ae oe Oe		<code>\addfontfeature{Ligatures={TeXOff,RequiredOff,CommonOff}}</code>
fi ffi fl ffl fj ffj ft		<code>‘ ‘ -- --- ! ‘ ? ‘ ’ ’ \ \ ae Ae oe Oe \ \ fi ffi fl ffl fj ffj ft</code>

9-6-16

Rare or Discretionary ligatures (dlig) are considered optional by the font designer, and the set is therefore not enabled by default. There is also the set of Historic ligatures (hlig) that implements ligatures that were once common in documents but are nowadays not often seen so are useful only if you want to give your document a certain look and feel. Which ligatures end up in which set (or are provided at all) differs unfortunately from family to family as we can see in the next example. You may have to try out what happens if you enable one or the other feature.

		<code>\usepackage{fontspec}</code>	
ch ck Th tt tz st ct sp		<code>\fontspec{Libertinus Serif}</code>	ch ck Th tt tz st ct sp \ \
ch ck Th tt tȝ	(rare)	<code>\addfontfeature{Ligatures=Rare}</code>	ch ck Th tt tz \hfill (rare) \ \
ſt ct (not sp)	(historic)	<code>\addfontfeature{Ligatures=Historic}</code>	st ct (not sp) \hfill (historic)
		<code>\par \medskip</code>	
st ct sp Qu		<code>\fontspec{BaskervilleF}</code>	st ct sp Qu \ \
ſt ct ſp	(rare)	<code>\addfontfeature{Ligatures=Rare}</code>	st ct sp \hfill (rare) \ \
Qu	(historic)	<code>\addfontfeature{Ligatures=Historic}</code>	Qu \hfill (historic)

9-6-17

Finally, there may be Contextuals ligatures (clig) that should, as the name indicates, be used in only certain contexts (typically when typesetting in specific languages) and are therefore not activated either by default. In predominately Latin fonts this feature is seldom implemented, and none of the fonts discussed in this book supports it.

Adjusting the font kerning The Kerning key (see Table 9.14 on the next page) is responsible for adding kerns (small negative or positive spaces) between adjacent letters to make their appearance visually uniform. This is activated by default, but in some special cases you may want to prohibit it using `Kerning=Off`. If you typeset text in

Value	feature	Value	feature
On	kern	Uppercase	csp
Off	-kern	ResetAll	—

UppercaseOff turns the feature off.

Table 9.14: Values accepted by the Kerning key

capitals, then the normal kerning can be improved in many fonts by using the value Uppercase (scsp). The differences are fairly small, but in the eyes of the font designer they improve legibility. In the example the first line shows the default result, the second adjusts the vertical position of the hyphen and shortens the parentheses a bit, and in the third line we also add the extra kerning that makes the line minimally wider:

Stylistic features The stylistic feature tags ss01 to ss20, the alternate feature tag salt, as well as the character variant feature tags cv01 to cv99 are sometimes available in OpenType fonts and can be used to select glyph shape variants.

The cv<num> tags (character variants) have been invented primarily for orthographic variations of individual characters, which is why there are so many of them. They are often used for situations where Unicode has only a single slot but varying regional or typographic traditions exist and the user might prefer one variant over the other.

The ss<num> tags (stylistic sets) on the other hand were meant to alter sets of glyphs typically for typographic rather than orthographic reasons. Without a definite purpose it was up to the font designers to decide what kind of features each of their sets implements. Technically the sets are more than just additive, e.g., effects on some glyph may differ depending on enabling ss01, ss02, or both of them. Sometimes combining them just produces undesirable effects; see Example 9-6-20 on page 724. However, in most fonts their effects are orthogonal to each other. Stylistic sets got supported early on by Adobe InDesign, and as a result many fonts offer a collection of them (usually altering just a few characters per set) to allow users to easily choose their favorite combination.

The alternate feature salt is a single set and predates the stylistic sets, but being supported in Adobe Illustrator, font designers often add variants both into ss and salt. The traditional implementation of this feature in software was to offer an interactive menu from which the user is able to pick and choose. Thus, in many cases one finds variants in this set that do not naturally work in unison. This makes it less

attractive for use with L^AT_EX because through fontspec it is possible to activate the whole set but not individual variants from it; see Example 9-6-22 on the next page.

The fontspec package offers interfaces for these features through the keys `CharacterVariant`, `StylisticSet`, `Alternate`, and `Style`, but for these it is usually simpler to specify them through the generic `RawFeature` interface, which is what we do below. Later examples show the other interfaces.

For example, in the `otfinfo` output for `XCharter-Roman.otf` on page 715 we see `cv01` and `ss01` being listed. Unfortunately, we do not get any information about what the character variation or the stylistic set actually do to our font. In this font `cv01` alters the look of the oldstyle numeral “1”, and `ss01` changes the glyph used for “ß” in small capitals.

Activating a feature works by specifying the feature name (with an optional + in front) as the value to `RawFeature`, deactivating by preceding the name with a -. Some fonts have several character variants for a single character, in which case the variants can be accessed numerically, e.g., `RawFeature={+cv01=2}`.

9-6-19

```

\usepackage{fontspec} \setmainfont{XCharter}[Numbers=OldStyle]
123 \addfontfeature{RawFeature = +cv01} 123
123 123 123 \addfontfeature{RawFeature = -cv01} 123 \\
GRUß ß GRUSS ß \textsc{Gruß} ß \addfontfeature{RawFeature = ss01} \textsc{Gruß} ß

```

If you are lucky, then this is documented as part of the font documentation, but with the free fronts we discuss in Chapter 10 this is regrettably seldom the case. So how did we know how to prepare the examples in this section? The answer is unfortunately “by opening the font files in the font editor fontforge and examining the substitutions that are specified for the different stylistic sets”.

This is certainly not a good way to do it and given that within the T_EX distribution 34 font families implement alternates and 75 specify one or more stylistic set, there is a treasure hidden here waiting to be dug up. I hope that one day somebody finds the time and documents what exactly these variants do font by font.

Without that being available, all we can do now is to exhibit a few more interesting examples that show that it is a pity that the font designers went through the trouble of producing interesting alternatives but then stopped short and forgot to tell people about them.¹

Our next example involves the font family *Cormorant Garamond*. It supports several stylistic sets of which we show two: `ss03` alters the shape of several characters and symbols (in fact more than we display) and `ss04` changes the dieresis accents to display a small “e” instead. Note that while it is in principle possible to activate several stylistic sets in parallel, it does not always work if they try to alter the same characters; in this case, the “ä” was already changed by `ss03`, and `ss04` was not applied.

It also offers a few individual character variants; we show those for “Q” and “f”. Finally, `salt` is also available, which alters some strokes in a number of characters;

¹With commercial fonts this documentation is more often available, which is the main reason why we show how to access these features.

again we display only a selection of those being affected.

a ä g U W w y æ ††	<code>\usepackage{fontspec} \setmainfont{Cormorant Garamond}</code>

9-6-20

Some fonts offer more than one salt set, in which case the sets are numbered starting with zero representing the default set. This makes addressing such sets using `RawFeature={salt=<num>}` a bit awkward. As an alternative, you can use `Alternate=<num>` in this case.

Whether a feature is implemented as a character variant, as a stylistic set, and/or as an alternative is sometimes a bit arbitrary. For example, EB Garamond also offer Q's with long tails but does this through a stylistic set that also affects small capitals. Like XCharter it also knows about uppercase "ß", but its stylistic set affects the lowercase form too.¹

GRUSS ß GRUß ss	<code>\usepackage{fontspec} \setmainfont{EB Garamond}</code>	
Query QQ Query QQ	<code>\textsc{Gruß} ß {\addfontfeature{StylisticSet=5}\textsc{Gruß} ß} \\</code>	
	<code>Query \textsc{Qq} {\addfontfeature{StylisticSet=6}Query \textsc{Qq}}</code>	

9-6-21

Our final example shows one of the Libertinus families, which all offer the same stylistic sets. The different sets alter only a few characters each, so if you like the lowered dieresis (which was customary in German typography) and you prefer the old form "SS" for an uppercase "ß", you could select `ss01` and `ss04`. In this font `salt` (or `Style=Alternate`) is implemented to select all stylistic sets (except for `ss04`, which is unfortunately the wrong way around because for German orthography lowercase ß should not be replaced by SS) but does in fact also contain a few other variants (such as for h and y) not included in the stylistic sets.

9-6-22

¹Which is rather strange for German eyes!

<i>Value</i>	<i>feature</i>	<i>Value</i>	<i>feature</i>	<i>Value</i>	<i>feature</i>
Alternate	salt	Swash	swsh	HorizontalKana	hkna
Cursive	curs	Titling	titl	VerticalKana	vkna
Historic	hist	Uppercase	case	Ruby	ruby
Italic	ital			ResetAll	—

Individual features can be turned off by appending Off to the name.

Table 9.15: Values accepted by the Style key

Style features In contrast to the stylistic sets discussed in the previous section, the Style features are intended for changes that conceptually change the style of the whole script (even though technically it may affect only some glyphs). It accepts nine different values, five of which (in the second column of Table 9.15) are predominately relevant for Asian or Arabic scripts, e.g., adjustments if Kana characters are written horizontally or vertically. Cursive changes the positions of diacritics in cursive scripts like Arabic, and Italic uses italic glyphs for Latin characters if available as part of Asian fonts. Finally, Ruby provides so called ruby characters, which are smaller Kana glyphs, generally in superscripted form, used to clarify the meaning of Kanji characters that may be unfamiliar to the reader.¹

The values from the first column are of considerably more interest. We have already discussed Alternate (salt), though as mentioned before, with that feature you have to check if the alternate glyphs really form a coherent set before you activate it.

Letterforms in scripts change over time, and what was once common may now appear anachronistic. If implemented, Historic (hist) brings back the historic forms. For example, EB Garamond replaces the lowercase s with a long-s form. The trouble with this approach is that it is often unconditionally done, and that is historically wrong. With L^AT_EX this means we have to load the font twice, with and without the feature applied and explicitly access the “short s” through a command.²

Providing historical letterforms

```

Thif paffef fucefffully! \usepackage{fontspec} \setmainfont{EB Garamond}[Style=Historic]
— (wrong)               \newfontfamily\normalEBG{EB Garamond} \newcommand\s{{\normalEBG s}}
This paffes fucefsfully! This passes successfully! \\ --- (wrong) \\
— (correct)              Thi\s\ passe\s\ succes\s fully! \\ --- (correct)

```

9-6-23

The value Swash changes some letter shapes so that they show some typographical flourish, such as some extra or lengthened stroke, exaggerated serifs, etc. L^AT_EX

Enabling Swash letters

¹None of the free font families we discuss in this book supports any of these features. Across all fonts available from CTAN, only two support Ruby, and none supports the other features.

²EB Garamond changes other characters as well, but with fonts that only change s to long-s, a probably better approach would be to not activate Historic feature and instead enter the correct Unicode character directly in the source.

offers the commands `\swshape` and `\textsw` to access them as a shape, but with `fontspec` in Unicode engines you have to explicitly set this up. Examples for how to do this are given in Example 9-6-7 on page 713.

*Adjustment for text
with only capital
letters*

Punctuation marks, dashes, parentheses, and so forth are usually designed for mixed case text and do not work that well if text is set completely in capital letters. For the use case `fontspec` supports `Uppercase` (case), which makes tiny adjustments if supported by the font as shown in the next example:

```
<<INRIA-FAMILY (NORMAL)>> \usepackage{fontspec}
<<INRIA-FAMILY (CASE)>> \fontspec{Inria Serif} <<INRIA-FAMILY (NORMAL)>> \
\addfontfeature{Style=Uppercase} <<INRIA-FAMILY (CASE)>>
```

9-6-24

Finally, there may be special support for typesetting headings/titles through the value `Titling` (`titl`). This feature replaces some glyphs with corresponding forms designed specifically for titling.

Scripts and languages As OpenType fonts can contain many glyphs, they often support several scripts and languages. “Script” in this context refers to the alphabet used, e.g., German, French, English, etc., all use the Latin script, while Arabic and Persian languages use the Arabic script. It is also possible that a single language can be typeset using different scripts. OpenType knows about more than hundred scripts and several hundred languages, and with the keys `Script` and `Language` you can ask for special support from the font if available.

The important point here is that based on the language/script combination the font may offer additional font features or activate or deactivate some by default. Details are given in the `fontspec` documentation [172], and if you intend to typeset in scripts other than Latin, you should study its section on that topic. In most other cases using the default language and script (i.e., not providing values) is sufficient.

Features not discussed in detail As mentioned, there are many more font features than we can reasonably describe in the available space. So here is a brief summary of seldom needed features that are also supported by `fontspec` if necessary.

The `Contextuals` key normally covers glyph substitutions that need to vary based on their relative position in words, e.g., initial, medial, and final forms in Greek. In some fonts it is also used for other type of “contexts”. Here are two random examples: in *Playfair Display* one can get arrows through some sort of ASCII input, and in *Libertinus* the Q changes its tail if followed by u or v, but not otherwise. Such `Alternate` contextuels are turned on by default, so in the example we turn them off, to show the differences:

```
\usepackage{fontspec}
\fontspec{Playfair Display} -> <- <-> \hfill
\addfontfeature{Contextuals=AlternateOff} -> <- <-> \par
\fontspec{Libertinus Serif} SPQR Qu Qv \hfill
\addfontfeature{Contextuals=AlternateOff} SPQR Qu Qv
```

9-6-25

The `Diacritics` key defines how diacritics and base characters should be combined. This is usually automatically handled by the font based on the current script or language. With the `LocalForms` key (feature `loc1`) it is possible to enable or disable language-specific glyph substitutions. If implemented by the font, it is automatically activated. There are also a number of features largely related to Chinese, Japanese, and Korean (CJK) typesetting. These are supported through the keys `Annotation`, `CharacterWidth`, `CJKShape`, and `Vertical`.

Specialized keys

With Lua \TeX it is possible to use the `Renderer` key to direct the engine to support certain font rendering technologies, e.g., the HarfBuzz text shaping library. This is under active development; consult the fontspec documentation [172] for details.

Different ways of specifying font features

The examples in the previous sections have shown a number of ways to enable or disable font features. As a summary, you can alter the features of the current font by using `\addfontfeature`, as done in several examples.

At declaration time you can specify features that apply to all font faces being set up by specifying them at the top level of the optional *feature-list* argument of `\setmainfont`, `\setsansfont`, etc. This was, for example, done in Example 9-6-15 on page 720 or 9-6-19 on page 723.

But it is also possible to apply certain features only to specific shapes, e.g., upright, italics, slanted, or swash. This can be done with the help of the keys `UprightFeatures`, `ItalicFeatures`, `SlantedFeatures`, and `SwashFeatures` and the corresponding bold fonts, i.e., `BoldFeatures`, `BoldItalicFeatures`, `BoldSlantedFeatures`, and `BoldSwashFeatures`. Features for small capitals are set up with `SmallCapsFeatures`. This is orthogonal to the other keys because any of the shapes can (in principle) be in upper/lower case or in small caps; thus, there is only this one key. This method was already applied in Example 9-6-11 on page 718.

Yet another way is to specify them as part of a `FontFace` key in which case they apply only to that particular font face as exhibited in Example 9-6-7 on page 713.

The rationale behind the different approaches is to make common tasks simple while offering flexibility when dealing with complex fonts or those that have unusual setups. The fontspec manual [172] covers many more examples of how to specify font features in different circumstances.

Specifying AAT or Graphite font features

When using X \mathbb{Y} \TeX , there are additional font technologies available that offer their own set of feature values. These can also be managed with the fontspec package, but as this is mainly useful with commercial fonts or system fonts on the Macintosh, we do not cover them here. Refer to [172] if you want to use such fonts with X \mathbb{Y} \TeX .

9.6.6 General configuration options

By default fontspec automatically attempts to adjust the math fonts to fit to your text font selection, which may not be appropriate if you have loaded a math font support

 Preventing
fontspec from
altering the
math setup

package, such as those discussed in Chapter 12. If you want to prevent any math setup alterations, use the `no-math` package option.

Config files

On page 710 we already discussed how to configure default setups for individual font families. On top of that you can provide your own `fontspec.cfg` file. If such a file is found by `fontspec`, it is loaded, unless you specify the package option `no-config`. The distribution already contains such a file setting two important defaults: turning on TeX ligatures and altering the typewriter family to have fixed spaces and no hyphenation:

```
\defaultfontfeatures[\rmfamily,\sffamily]{Ligatures=TeX}
\defaultfontfeatures[\ttfamily]
  {WordSpace={1,0,0},HyphenChar=None,PunctuationSpace=WordSpace}
```

If you intend to provide your own config file, you should probably copy these two declarations into it.

Silence warnings

The `fontspec` package may write some warnings in certain situations. If you prefer not to get those on the terminal, but only in the `.log` file, use the package option `quiet`. If they should not appear anywhere, use `silent` instead.

9.6.7 unicodefonttable — Displaying font tables for larger fonts

The `nfssfont.tex` file described in Section 9.5.9 does not help you if you are interested in looking for fonts to use with `fontspec` in Unicode engines, because it can only produce font tables displaying the first 256 glyphs of such a font and OpenType or TrueType fonts often contain several thousand glyphs.

To tabulate such fonts use the `unicodefonttable` package developed by the author. It offers you a flexible command to generate glyph tables for any font that can be used with Unicode TeX engines, either listing the full glyph set or any portion thereof.

`\displayfonttable*[key/value list]{font-name}[font-features]`

The mandatory *font-name* should be given in a form understood by `fontspec`, and the optional *font-features* is a key/value list in the form you would use it in `\addfontfeature` or in the optional argument of `\setmainfont`. Together they describe the font to be tabled. The optional *key/value list* offers you the possibility to customize the glyph table for which we give a few examples below, but for the full flexibility we refer you to the package documentation.

The starred form of the command is intended for displaying 8-bit fonts and alters some default settings to produce reasonable table layouts in that case. For example, it makes little sense to display Unicode block titles, if the only blocks shown are the first and possibly the second (*Basic Latin* and *Latin-1 Supplement*) or if the 8-bit font contains other glyphs unrelated to the Unicode blocks. Thus, by default they are not shown, and the table becomes more compact.

The next example show the Computer Modern Math symbol font (`cmsy10`). Besides using the starred form, we supply the key `noheader`, which omits a table caption, and restrict the processing range with `range-end`. The latter does not

change the output, but it makes processing a bit faster, because cmsy is a 7-bit font, so it is pointless to check the higher bits for existing glyphs.

```
\usepackage{unicodetontable}
\displayfonttable*[noheader,range-end=7F]{cmsy10}
```

	0	1	2	3	4	5	6	7	8	9	A	B	C	D	E	F
U+0000-000F	—	·	×	*	÷	◇	±	∓	⊕	⊖	⊗	⊘	⊙	◯	◊	●
U+0010-001F	×	≡	⊆	⊇	≤	≥	≲	≳	≈	≈	⊂	⊃	⊂	⊃	↖	↗
U+0020-002F	←	→	↑	↓	↔	↗	↘	≈	⇐	⇒	↑	↓	↔	↖	↗	∞
U+0030-003F	/	∞	∈	∋	△	▽	/	,	∇	∃	¬	∅	ℝ	ℑ	ℒ	⊥
U+0040-004F	ℵ	ℳ	ℳ	ℳ	ℳ	ℳ	ℳ	ℳ	ℳ	ℳ	ℳ	ℳ	ℳ	ℳ	ℳ	ℳ
U+0050-005F	ℳ	ℳ	ℳ	ℳ	ℳ	ℳ	ℳ	ℳ	ℳ	ℳ	ℳ	ℳ	ℳ	ℳ	ℳ	ℳ
U+0060-006F	ℳ	ℳ	ℳ	ℳ	ℳ	ℳ	ℳ	ℳ	ℳ	ℳ	ℳ	ℳ	ℳ	ℳ	ℳ	ℳ
U+0070-007F	√	Π	∇	∫	∫	∫	∫	∫	∫	∫	∫	∫	∫	∫	∫	∫

9-6-26

You may be interested in only a certain part of a font, for example, in the letter-like Unicode block, which starts at 2100 and ends at 213F. In that case you can use `range-start` and `range-end` to denote the area of interest. We suppress the overall header again, because we now get Unicode Block titles (or rather one such title because of our range). We also change the placement of the hex digits to appear below each block title using `hex-digits` (supported values are `block`, `foot`, `head` (default), `head+foot`, and `none`) and shortening the `hex-digits-row-format` on the left:

```
\usepackage{unicodetontable}
\displayfonttable[range-start=2100,range-end=213F,noheader,
hex-digits=block,hex-digits-row-format=U+#1]{TeX Gyre Pagella}
```

	0	1	2	3	4	5	6	7	8	9	A	B	C	D	E	F
U+2100	-	-	-	°C	-	-	-	ℰ	-	°F	-	-	-	-	-	h
U+2110	-	-	-	ℓ	-	-	№	®	ø	-	-	-	-	-	R	-
U+2120	SM	-	TM	-	-	-	Ω	U	-	-	K	Å	-	-	e	-
U+2130	-	-	-	-	-	N	∩	λ	7	-	-	-	-	-	-	-

9-6-27

Total number of glyphs shown from TeX Gyre Pagella: 20

As you can see, there are some statistics shown at the bottom. With the key `nostatistics` you can omit them; alternatively, `statistics-format` lets you set up your own text. This key allows you to use `#1` to get the current font name and `#2` to display the glyph count; e.g.,

```
...,statistics-format=This block contains #2 glyphs in #1,...
```

would display “This block contains 20 glyphs in TeX Gyre Pagella” in the previous example. Similar keys exist for the header (`title-format`) and the continuation

header (title-format-cont); within their values you can use #1 for the font name and #2 for the font features, if given. You can test for that with \IfValueTF and act accordingly. Note that these table headers are best set with a \caption command in order to come out right.

If you do not like to see Unicode block titles displayed, you can adjust this with the key display-block. It accepts the values titles (default), rules, or none. The last two save valuable space at the cost of less readability in large fonts.

*Fill the table
with two fonts*

It is sometimes useful to compare two fonts with each other by filling the table with glyphs from a secondary font if the primary font is missing them. For example, the next display shows two rows of Latin Modern Math (black glyphs), and instead of showing a missing glyph symbol in most slots, we rope in glyphs from New Computer Modern Math, which has a much larger glyph set. By default these substituted glyphs are set in red (compare-color) on gray background (compare-bg-color). We changed it in the example to use the blue available in the book and turned off the general coloring for hex digits and range info (color), which is normally done in blue. We also drastically shortened the row title (hex-digits-row-format) to save space:

```
\usepackage{unicodetable} \fonttablesetup{noheader,nostatistics}
\displayfonttable[display-block=none,color=none,hex-digits-row-format=#1,
                 compare-with=NewCMMath-Regular.otf,compare-color=blue,
                 range-start=2A00,range-end=2A1F]{latinmodern-math.otf}
```

	0	1	2	3	4	5	6	7	8	9	A	B	C	D	E	F
2A0	⊙	⊕	⊗	⋅	⊔	∏	∏	∞	∞	×	Σ	Σ	∫	∫	∫	∫
2A1	∫	∫	∫	∫	∫	∫	∫	∫	∫	∫	∫	∫	∫	∫	∫	∫

9-6-28

```
\fonttablesetup{key/value list}
```

Instead of or in addition to setting *key/values* on each table, it is also possible to alter the defaults, by specifying a *key/value list* in \fonttablesetup; for example, the starred form does this internally by setting nostatistics, display-block=none, hex-digits=head, range-end==FF. This can be overwritten on the table level; e.g., statistics would give you a statistics line even in an 8-bit font table.

There also exists a standalone unicodfont.tex file that, when processed with a Unicode engine, interactively asks you a few questions, calls \displayfonttable to generate a single font table, and then exits.

9.7 The low-level NFSS interface

While the high-level font commands are intended for use in a document, the low-level commands are mainly for defining new commands in packages or in the preamble of a document; see also Section 9.7.5. To make the best use of such font commands, it is helpful to understand the internal organization of fonts in L^AT_EX's font selection scheme (NFSS).

One goal of \LaTeX 's font selection scheme is to allow rational font selection, with algorithms guided by the principles of generic markup. For this purpose, it would be desirable to allow independent changes for as many font attributes as possible. On the other hand, font families in real life normally contain only a subset of the myriad imaginable font attribute combinations. Therefore, allowing independent changes in too many attributes results in too many combinations for which no real (external) font is available and a default has to be substituted.

\LaTeX internally keeps track of five independent font attributes: the “current encoding”, the “current family”, the “current series”, the “current shape”, and the “current size”. The encoding attribute was introduced in NFSS release 2 after it became clear that real support of multiple languages would be possible only by maintaining the character-encoding scheme independently of the other font attributes.

The values of these attributes determine the font currently in use. \LaTeX also maintains a large set of tables used to associate attribute combinations with external fonts (i.e., `.tfm` files that contain the information necessary for \TeX to do its job). Font selection inside \LaTeX is then done in two steps:

1. A number of font attributes are changed using the low-level commands `\fontencoding`, `\fontfamily`, `\fontseries`, `\fontshape`, `\fontsize`, or `\fontseriesforce` and `\fontshapeforce`.
2. The font corresponding to this new attribute setting is selected by calling the `\selectfont` command.

The second step comprises several actions. \LaTeX first checks whether the font corresponding to the desired attribute settings is known to the system (i.e., the `.tfm` file is already loaded), and if so, this font is selected. If not, the internal tables are searched to find the external font name associated with this setting. If such a font name can be found, the corresponding `.tfm` file is read into memory, and afterwards the font is selected for typesetting. If this process is not successful, \LaTeX tries to find an alternative font, as explained in Section 9.7.3.

9.7.1 Setting individual font attributes

Every font attribute has one command to change its current value. All of these commands accept more or less any character string as an argument, but only a few values make sense. These values are not hardwired into \LaTeX 's font selection scheme, but rather are conventions set up in the internal tables.

We have already used some of them in the previous sections; this section now covers all of the naming conventions used in the standard setup of \LaTeX . Obviously, anybody setting up new fonts for use with \LaTeX should try to obey these conventions whenever possible, because only a consistent naming convention can guarantee that appropriate fonts are selected in a generically marked-up document.

If you want to select a specific font using this interface — say, Computer Modern Dunhill bold condensed italic 14pt — a knowledge of the interface conventions alone is not enough, because for many of the combinations of the attributes there is no

<i>Weight Classes</i>		<i>Width Classes</i>		
Ultra Light	ul	Ultra Condensed	≈50%	uc
Extra Light	el	Extra Condensed	≈62.5%	ec
Light	l	Condensed	≈75%	c
Semi Light	sl	Semi Condensed	≈87.5%	sc
Medium (normal)	m	Medium	≈100%	m
Semi Bold	sb	Semi Expanded	≈112.5%	sx
Bold	b	Expanded	≈125%	x
Extra Bold	eb	Extra Expanded	≈150%	ex
Ultra Bold	ub	Ultra Expanded	≈200%	ux

To describe a series combine $\langle\text{weight}\rangle\langle\text{width}\rangle$ and drop any `m` unless this makes the specification empty.

Table 9.16: Weight and width classification of fonts

matching external font. You could try your luck by specifying something like the following set of commands:

```
\fontencoding{T1}\fontfamily{cmdh}\fontseries{bc}\fontshape{it}%
\fontsize{14}{16pt}\selectfont
```

This code would be correct according to the naming conventions, as we see in the following sections. Because this attribute combination does not correspond to a real font, however, \LaTeX would have to substitute a different font. This substitution mechanism may choose a font that is quite different from the one desired, so you should consult the font tables (in this and the following chapter) to see whether the desired combination is available. Section 9.7.3 provides more details on the substitution process.

Choosing the font family

The font family is selected with the command `\fontfamily`. Its argument is a character string that refers to a font family declared in the internal tables. The character string was defined when these tables were set up and is often a short letter sequence — for example, `cmr` for the Computer Modern Roman family. With newer fonts it is often rather lengthy and structured, e.g., `FiraSans-OfF`. See Section 10.1.3 on page 717 for the more modern naming conventions.

Unicode engines

When using Unicode engines, the `\fontfamily` command is normally of little value because fonts loaded with the `fontspec` package get some internal family name assigned, and it is therefore not easy to guess what family name to pass as an argument.

There is, however, a way to explicitly specify a font family name that can be used with `\fontfamily`; see Section 9.6 on page 705 for details.

Choosing the font series

The series attribute is changed with the `\fontseries` command. The series combines a weight and a width in its argument; and in the original font selection implementation it was not possible to alter only weight but not width, and vice versa. With the 2020 release of \LaTeX this has changed, and `\fontseries` can now be used to change only one of the subattributes. To force a specific weight and width combination you can use `\fontseriesforce`.

In the original font selection implementation a request to change the series always canceled the current one. This was reasonable because there were nearly no fonts available that offered anything other than a medium or a bold series. This has changed, and now there are families such as Noto Sans that offer 32 distinct series values. With the 2020 release of \LaTeX , the series management therefore changed to allow for independently setting the weight and the width attribute of the series.

In the naming conventions for the argument for the `\fontseries` command, the names for both the weight and the width are abbreviated so that each combination is unique. The conventions are shown in Table 9.16 on the preceding page.

These classifications can be combined as $\langle weight \rangle \langle width \rangle$ in the argument to `\fontseries`; e.g., `lc` would ask for a “light weight condensed width” series. If only a value for weight or only for width is given (e.g., `b` or `ec`), it means that the other aspect should be left unchanged. Thus, if the current series is `lc` and we are asking for `b`, then this would result in `bc`. If you want to ensure that you always get bold medium width unconditionally, you would have to use `bm` instead.¹

There is a special convention for medium (`m`) as that can denote either a weight or a width. Both a single `m` or double `mm` is interpreted as medium weight and width, and `m?` stands for medium weight and width unchanged and `?m` the other way around.

Handling weight and width requests independently from each other is done by the `\fontseries` command through a lookup table that maps the *current* and the *requested* series to a resulting *new* series value, e.g.,

$$b + c \rightarrow bc \quad \text{or} \quad ub + x \rightarrow ubx \quad \text{or} \quad bx + l \rightarrow lxx \quad \text{etc.}$$

This table is prefilled with reasonable mappings, but if necessary, it is possible to alter individual entries using `\DeclareFontSeriesChangeRule` declarations.

`\DeclareFontSeriesChangeRule{current}{request}{new}{alternative}`

This command specifies that when typesetting in *current* series and there is a *request* for a series change, then typesetting should continue with *new* series. If that series

¹For historical reasons the naming conventions for the series attribute when declaring fonts in font definition files is slightly different: there any instance of `m` (standing for medium in weight or width) is dropped, except when both weight and width are medium. The latter case is abbreviated with a single `m`.

For example, bold expanded would be `bx`, whereas medium expanded would be `x`, and bold medium would be `b`. This inconsistency is somewhat unfortunate, but given that there exist several hundred font families with `.fd` files, one has to live with it.

Abbreviation	Description
n	normal shape (upright and upper/lowercase letters)
it	<i>italic shape</i>
sl	<i>slanted or oblique shape</i>
sw	<i>Swash Letter Shape (seldom available)</i>
ui	upright italic shape (more a curiosity)
sc	SMALL CAPS SHAPE
scit	ITALIC SMALL CAPS SHAPE
scsl	SLANTED SMALL CAPS SHAPE
scsw	SWASH LETTER SMALL CAPS SHAPE
up ^a	(Return to) upright shape
ulc	(RETURN TO) Upper/Lower Case shape

^aChanges scit to sc, etc., but acts like ulc if current shape is sc, i.e., changes that to n.

Table 9.17: Shape classification of fonts

does not exist, the *alternative* series is tried instead. If that does not exist either, *request* is used unchanged. Of course, that series may not exist either, in which case standard font shape substitution kicks in; see Section 9.7.3 for details of what happens in that situation.

For combinations of *current* and *request*, for which no table entry exists, the *request* is used unconditionally as the new series.

Because m can stand for both medium weight and width in the naming convention, it cannot be used in the *request* to reset only weight or width to medium, e.g., when you want to get back from bc (bold condensed) to just c (condensed). For that case two special series names are provided: ?m (keep weight, reset width) and m? (reset weight, keep width). Thus, we can get from bold condensed to medium width condensed using `\fontseries{m?}`. If you use m in the *request*, it is interpreted as mm, i.e., resets both weight and width to medium.

Choosing the font shape

The `\fontshape` command is used to change the shape attribute. For the standard shapes, one- to four-letter abbreviations are used; these are shown in Table 9.17 together with an example of the resulting shape in the Latin Modern Roman family except sw in EB Garamond and scsw in Cinzel.

In the original font selection implementation, a request for a new shape always canceled the current one. With the 2020 release of L^AT_EX, this has changed, and `\fontshape` can now be used to combine small capitals with italics, slanted, or

swash letters, either by explicitly asking for `scit`, etc., or by asking for it when typesetting already in `sc` and so forth. With `\fontshapeforce`, you can force a specific selection as long as it actually exists as a font shape.

Again, this is supported by a table lookup, and just like with the series management, this table can be adjusted if necessary.

`\DeclareFontShapeChangeRule{current}{request}{new}{alternative}`

This declaration works like `\DeclareFontSeriesChangeRule` except that we look at *current* shape and *requested* shape. Another difference is that the table much more often specifies an *alternative* shape in addition to the desired *new* shape. For example, two such entries are

```
\DeclareFontShapeChangeRule {n} {sl}{sl} {it}
\DeclareFontShapeChangeRule {it}{sc}{scit}{scsl}
```

The first line says that if \LaTeX is typesetting in the “normal” shape and there is a request for a slanted shape, then it should try `sl`, and if that is not available, should try the `it` shape.¹

The second line says that `it` and `sc` should be combined to `scit`. But if that is not available, then `scsl` should be used. If that does not exist either, then the *request* shape, i.e., `sc`, is used, so that with Computer Modern or other fonts that have only upright small capitals we still see the old behavior of `sc` canceling `it`, or vice versa.²

Both `up` and `ulc` are “virtual” shapes. This means that they do not physically exist as font faces, but only as arguments to `\fontshape` to alter the current state; e.g., if the current shape is `scit`, then `up` changes that to `sc`, while `ulc` would change it to `it`. However, for compatibility reasons `up` acts a bit oddly; that is, if the current shape is `sc`, then it resets that as well. The reason is that in the past `\upshape` was always setting the shape back to `n` and some people have written `\scshape . . . \upshape` instead of just writing `\textsc{ . . . }`, so this usage is still supported.

*Compatibility
behavior of up*

This is all defined through `\DeclareFontShapeChangeRule` declarations and thus changeable, but there should seldom be a need for alterations. However, if you do not want or need this compatibility behavior of `up`, you could, for example, declare

```
\DeclareFontShapeChangeRule{sc}{up}{sc}{}
```

after which `sc` would no longer be canceled by `up`.

Choosing the font size

The font size is changed with the `\fontsize{size}{skip}` command. This is the only font attribute command that takes two arguments: the *size* to switch to and the baseline *skip* (the distance from baseline to baseline for this size). Font sizes are normally measured in points, so by convention the unit can be omitted. The same

¹Because of such declarations, fonts like Iwona (page –II 78) or Kurier (page –II 80) work without errors even though they have no slanted shape and have no substitution defined in their `.fd` files.

²The only difference to earlier years is that now there will be a `.log` entry stating that `scit` was tried but was found not to be available.

is true for the second argument. However, if the baseline skip should be a rubber length — that is, if it contains plus or minus — you have to specify a unit. Thus, a valid size change could be requested by

```
\fontsize{14.4}{17}\selectfont
```

Even if such a request is valid in principle, no corresponding external font may exist in this size. In this case, \LaTeX tries to find a nearby size if its internal tables allow for size correction or reports an error otherwise.

If you use fonts existing in arbitrary sizes (which is now possible for nearly all fonts), you can, of course, select any size you want. For example,

```
\fontsize{1in}{1.2in}\selectfont Happy Birthday
```

produces a birthday poster line with letters in a one-inch size. However, there is one problem with using arbitrary sizes: if \LaTeX has to typeset a formula in this size (which might happen behind the scenes without your knowledge), it needs to set up all fonts used in formulas for the new size. For an arbitrary size, it usually has to calculate the font sizes for use in subscripts and sub-subscripts (at least 12 different fonts). In turn, it probably has to load a lot of new fonts — something you can tell by looking at the transcript file. For this reason you may finally hit some internal limit if you have too many different size requests in your document. If this happens, you should tell \LaTeX which sizes to load for formulas using the `\DeclareMathSizes` declaration, rather than letting it use its own algorithm. See Section 9.8.5 for more information on this issue.

Choosing the encoding

A change of encoding is performed with the command `\fontencoding`, where the argument is the internal name for the desired encoding. This name must be known to \LaTeX , either as one of the predefined encodings (loaded by the kernel), loaded through the `fontenc` package or manually declared with the `\DeclareFontEncoding` command (see Section 9.8.3). A set of standard encoding names is given in Table 9.18 on the next page; you find a more complete set in [143].

\LaTeX 's font selection scheme is based on the (idealistic) assumption that most (or, even better, all) fonts for text are available in the same encoding as long as they are used to typeset in the same language. In other words, encoding changes should become necessary only if one uses pdf\LaTeX and is switching from one language to another. In that case it is normally the task of the language support packages (e.g., those from the `babel` system) to arrange matters behind the scenes.

If necessary, switching to, say, Greek or Cyrillic for individual words or short phrases can even be done on the fly by specifying `LGR` (Greek) or `T2A` (Cyrillic), and this is precisely what we have done in the examples in Sections 10.11 and 10.12. There the Greek sample text was generated with

```
\usepackage[LGR,T1]{fontenc}
{\fontencoding{LGR}\selectfont Σά βγεῖς στὸν πη\~\-γαίμδ γι.ὰ
τὴν \textbf{Ἰθάκη}, νὰ εὔχῃσαι νᾶναι \textit{μακρὺς} ὁ
δρόμος, γεμᾶτος περιπέτειες, γεμᾶτος \textsc{γνώσεις}}
```

Encoding	Description	Declared by
TU	ℒ _{TeX} text encoding for Unicode engines X ₃ TeX and LuaTeX	ℒ _{TeX}
T1	ℒ _{TeX} text encoding (Latin) a.k.a. “Cork” encoding	ℒ _{TeX}
TS1	ℒ _{TeX} symbol encoding (Latin)	ℒ _{TeX}
T2A,B,C	ℒ _{TeX} text encodings (Cyrillic)	Cyrillic support packages
T3	ℒ _{TeX} phonetic alphabet encoding	tipa package
TS3	ℒ _{TeX} phonetic alphabet encoding (extra symbols)	tipa package
T5	ℒ _{TeX} text encoding (Vietnamese)	—
OT1	(old) T _E X text as defined by Donald Knuth	ℒ _{TeX}
OT2	(old) T _E X text for Cyrillic languages (obsolete)	Cyrillic support packages
OT4	(old) T _E X text with extensions for the Polish language	—

OMS	T _E X math symbol as defined by Donald Knuth	ℒ _{TeX}
OMX	T _E X math extended symbol as defined by Donald Knuth	ℒ _{TeX}
X2	Extended text encoding (Cyrillic)	Cyrillic support packages
U	Unknown encoding (for fonts containing arbitrary symbols)	ℒ _{TeX}
L..	Local encoding (for private encodings)	—
LGR	Commonly used Greek encoding	Greek support packages
LY1	Alternative to T1 encoding	Y&Y

Table 9.18: Standard font encodings used with ℒ_{TeX}

Of course, for proper language support, additional work would be necessary, such as changing the hyphenation rules (we got by, by specifying one explicit hyphen point).

With older Type 1 fonts, the T1 encoding is unfortunately not fully implementable. The following five characters are likely to show up as blobs of ink (indicating a missing glyph in the font) or substitutions (in case of the per thousand and per ten thousand symbols). As you can see, qpl (the Palatino clone by T_EX Gyre) and most of the fonts discussed in Chapter 10 do not have these problems.

Potential T1
encoding problems

Computer Modern:

j ŋ Đ %_o %_{oo}

Times (old PostScript):

■ ■ ■ %_o %_{oo}

Palatino (old PostScript):

■ ■ ■ %_o %_{oo}

Palatino (new T_EX Gyre):

j ŋ Ñ %_o %_{oo}

```
\usepackage[T1]{fontenc}
\fontfamily{cmr}\selectfont Computer Modern:\\
\j{} \ng{} \NG{} \textperthousand{} \textpertenthousand \par
\fontfamily{ptm}\selectfont Times (old PostScript):\\
\j{} \ng{} \NG{} \textperthousand{} \textpertenthousand \par
\fontfamily{ppl}\selectfont Palatino (old PostScript):\\
\j{} \ng{} \NG{} \textperthousand{} \textpertenthousand \par
\fontfamily{qpl}\selectfont Palatino (new \TeX\ Gyre):\\
\j{} \ng{} \NG{} \textperthousand{} \textpertenthousand
```

9-7-1

As explained in Section 9.5.6, the situation for TS1 is even worse — sometimes half the glyphs from that encoding are not available in a legacy PostScript font, which is another reason to avoid the old PSNFSS packages listed in Table 9.8 on page 691, despite their nice, memorable names.

9.7.2 Setting several font attributes

When designing page styles (see Section 5.4) or layout-oriented commands, you often want to select a particular font — that is, you need to specify values for all attributes. For this task \LaTeX provides the command `\usefont`, which takes four arguments: the encoding, family, series, and shape. The command updates those attributes and then calls `\selectfont`. If you also want to specify the size and baseline skip, place a `\fontsize` command in front of it. For example,

```
\fontsize{14}{16pt}\usefont{OT1}{cmdh}{bc}{it}
```

would produce the same result as the hypothetical example on page 732.

Besides `\usefont`, \LaTeX provides the `\DeclareFixedFont` declaration, which can be used to define new commands that switch to a completely fixed font. Such commands are extremely fast because they do not have to look up any internal tables. They are therefore very useful in command definitions that have to switch back and forth between fixed fonts. For example, for the `doc` package (see Chapter 17), one could produce code-line numbers using the following definitions:

```
\DeclareFixedFont\CodelineFont{\encodingdefault}{\familydefault}
                                {\seriesdefault}{\shapedefault}{7pt}
\newcommand\theCodelineNo{\CodelineFont\arabic{CodelineNo}}
```

As you can see from the example, `\DeclareFixedFont` has six arguments: the name of the command to be defined, followed by the five font attributes in the NFSS classification. Instead of supplying fixed values (except for the size), the built-in hooks that describe the main document font are used (see also Section 9.3.6). Thus, in the example above `\CodelineFont` still depends on the overall layout for the document (via the settings of `\encodingdefault` and other parameters). However, once the definition is carried out, its meaning is frozen, so later changes to the defaults have no effect.

9.7.3 Automatic substitution of fonts

Whenever a font change request cannot be carried out because the combination is not known to \LaTeX , it tries to recover by using a font with similar attributes. Here is what happens: if the combination of encoding scheme, family, series, and shape is not declared (see Section 9.8.1), \LaTeX tries to find a known combination by first changing the shape attribute to a default. If the resulting combination is still unknown, it tries changing the series to a default. As a last resort, it changes the family to a default value. Finally, the internal table entry is looked up to find the requested size. For

example, if you ask for `\ttfamily\bfseries\itshape` — a typewriter font in a bold series and italic shape (which usually does not exist) — then you get a typewriter font in medium series and upright shape, because \TeX first resets the shape before changing the series. If, in such a situation, you prefer a typewriter font in medium series with italic shape, you have to announce your intention to \TeX using the sub function, which is explained on page 743.

The substitution process never changes the encoding scheme, because any alteration could produce wrong characters in the output. Recall that the encoding scheme defines how to interpret the input characters, while the other attributes define how the output should look. It would be catastrophic if, say, a £ sign were changed into a \$ sign on an invoice just because the software tried to be clever.

Thus, every encoding scheme must have a default family, series, and shape, and at least the combination consisting of the encoding scheme together with the corresponding defaults must have a definition inside \TeX , as explained in Section 9.8.3.

9.7.4 Substituting the font family if unavailable in an encoding

Given that pdf \TeX can only handle fonts with up to 256 glyphs, a single font encoding can support only a few languages. The T1 encoding, for example, does support many of the Latin-based scripts, but if you want to write in Greek or Russian, you need to switch encodings to LGR or T2A. Given that not every font family offers glyphs in such encodings, you may end up with some default family (e.g., Computer Modern) that does not blend in well. For example, when typesetting in a sans serif font such as Montserrat, the Greek characters look rather out of place.

9-7-2

The root of \TeX
is $\text{\TeX}\nu\iota\kappa\eta$.

```
\usepackage[greek,english]{babel}
\fontfamily{Montserrat-LF}\selectfont
The root of \TeX\ is \foreignlanguage{greek}{\text{\TeX}\nu\iota\kappa\eta}.
```

For such cases NFSS offers `\DeclareFontFamilySubstitution`.

```
\DeclareFontFamilySubstitution{encoding}{family}{substitute-family}
```

This declaration tells NFSS that the request for the *encoding* while typesetting in a certain font *family* should be fulfilled by substituting this family with *substitute-family*. The declaration should be made in the document preamble before the font is actually used.

In the example below we use Plex Sans instead of the default to typeset the Greek word. It is not perfect but is clearly better than the default that we got in Example 9-7-2. Some of the other families exhibited in Section 10.11 on page 106 would have worked as well.

9-7-3

The root of \TeX
is $\text{\TeX}\nu\iota\kappa\eta$.

```
\usepackage[greek,english]{babel}
\DeclareFontFamilySubstitution{LGR}{Montserrat-LF}{IBMPlexSans-TLF}
\fontfamily{Montserrat-LF}\selectfont
The root of \TeX\ is \foreignlanguage{greek}{\text{\TeX}\nu\iota\kappa\eta}.
```

If you use font support packages to set up your font families (e.g., `montserrat` in this case), it may need a bit of detective work to figure out the actual font family name that needs to go into the *family* argument, but with the help of all the tables in Chapter 10, it should be manageable.

9.7.5 Using low-level commands in the document

The low-level font commands described in the preceding sections are intended to be used in the definition of higher-level commands, either in class or package files or in the document preamble.

Whenever possible, you should avoid using the low-level commands directly in a document if you can use high-level font commands like `\textsf` instead. The reason is that the low-level commands are very precise instructions to switch to a particular font, whereas the high-level commands can be customized using packages or declarations in the preamble. Suppose, for example, that you have selected Computer Modern Sans in your document using `\fontfamily{cmss}\selectfont`. If you later decide to typeset the whole document with other fonts by applying some font support package, then this would change only those parts of the document that do not contain explicit `\fontfamily` commands.

9.8 Setting up new fonts for NFSS

Setting up new fonts for use with \LaTeX basically means filling the internal font selection tables with information necessary for later associating a font request in a document with the external `.tfm` file containing character information used by \LaTeX . Thus, the tables are responsible for associating

```
\fontencoding{T1}\fontfamily{lmtt}\fontseries{lc}\fontshape{sl}%
\fontsize{10}{12}\selectfont
```

i.e., Latin Modern Typewriter light condensed slanted 10 point in T1 (Cork) encoding, with the external file `ec-lmtlco10.tfm`. To add new fonts, you need to reverse this process. For every new external font you have to ask yourself five questions:

1. What is the font's encoding scheme — that is, which characters are in which positions?
2. What is its (desired) family name in \LaTeX ?
3. What is its series (the combination of weight and width)?
4. What is its shape?
5. Is it a scalable font, or if not, what is its size?

The answers to these questions provide the information necessary to classify the external font according to the \LaTeX conventions, as described in Section 9.7.

However, users are not really expected to set up fonts by themselves. This is usually left to a few experts that, to date, have provided font support for several

hundred font families — as Chapter 10 impressively proves where we show examples of more than one hundred high-quality free families.

We therefore give only a brief overview about the commands available to set up font support, to the extent helpful for troubleshooting strange behavior or for making small adjustments like providing a desired font substitution. If necessary, the gory details can be found in [113].

9.8.1 Declaring new font families and font shape groups

The declarations discussed in this section are normally used only inside `.fd` files (font definition files), which should normally not be changed. With some caution, it is however possible to use them in the document preamble (or in packages) to adjust some font family behavior. How this can be done is explained in Section 9.8.2 on page 746.

Each family/encoding combination must be made known to \LaTeX through the command `\DeclareFontFamily`.

```
\DeclareFontFamily{encoding}{family}{loading-code}
```

The first two arguments are the *encoding* scheme and the *family* name. The third is usually empty, but it may contain special code for font loading and is explained on page 744. Thus, if you want to introduce a new family — say, Latin Modern Typewriter in T1 encoding scheme — you would write

```
\DeclareFontFamily{T1}{lmtt}{\hyphenchar\font=-1}
```

In this case the last argument contains code to suppress hyphenation; see page 744.

A font family normally consists of many individual fonts. Instead of announcing each family member individually to \LaTeX , you have to combine fonts that differ only in size and declare them as a group. Such a group is entered into the internal tables of \LaTeX with the command `\DeclareFontShape`.

```
\DeclareFontShape{encoding}{family}{series}{shape}
{list of sizes and external font(s)}{loading-code}
```

The first four are the *encoding* scheme, the *family* name, the *series* name, and the *shape* name under which you want to access these fonts later. The fifth argument is a *list of sizes and external font* names, given in a special format that we discuss below. The sixth argument is usually empty; its use is explained on page 744.

We first show a few examples and introduce terminology; then we will discuss all the features in detail.

As an example, an NFSS table entry for Computer Modern Dunhill medium (series) upright (shape) in the encoding scheme “ \TeX text” could be entered as

```
\DeclareFontShape{OT1}{cmdh}{m}{n}{ <10> cmdunh10 }{}
```

assuming that only one external font for the size 10pt is available. If you also have this font available at 12pt (scaled from 10pt), the declaration would be

```
\DeclareFontShape{OT1}{cmdh}{m}{n}{ <10> <12>cmdunh10 }{}
```

If the external font is available in all possible sizes, the declaration becomes very simple. This is the case for Type 1 PostScript (outline) fonts or when the driver program is able to generate fonts on demand by calling METAFONT.

For example, for our introductory example Latin Modern Typewriter light condensed (series) slanted (shape) in the \LaTeX T1 encoding scheme would be entered as

```
\DeclareFontShape{T1}{lmtt}{lc}{sl}{<-> ec-lmtlco10}{}
```

This example declares a size range with two open ends (no sizes specified to the left and the right of the `-`). As a result, the same external `.tfm` file (`ec-lmtlco10`) is used for all sizes and is scaled to the desired size. If you have more than one `.tfm` file for a font — as is the case for Latin Modern Typewriter medium upright — the declaration could be

```
\DeclareFontShape{T1}{lmtt}{m}{n}{<-8.5> ec-lmtt8  
 <8.5-9.5> ec-lmtt9 <9.5-11> ec-lmtt10 <11-> ec-lmtt12}{}
```

In this case different external fonts are used for different size ranges.

The preceding examples show that the fifth argument of `\DeclareFontShape` consists of size specifications surrounded by angle brackets (i.e., `<...>`) intermixed with loading information for the individual sizes (e.g., font names). The part inside the angle brackets is called the “size info”, and the part following the closing angle bracket is called the “font info”. The font info is further structured into a “size function” (often empty) and its arguments; we discuss this case below. Within the arguments of `\DeclareFontShape`, blanks are ignored to help make the entries more readable.¹ In the unusual event that a real space has to be entered, you can use `\space`.

Size functions

If an `*` appears in the font info string, everything to the left of it forms the function name, and everything to the right is the argument. If there is no asterisk, as in all of the examples so far, the whole string is regarded as the argument, and the function name is “empty”.

Based on the size requested by the user, size functions produce the specification necessary for \LaTeX to find the external font and load it at the desired size. They are also responsible for informing the user about anything special that happens. For example, some functions differ only in terms of whether they issue a warning. This

¹This is true only if the command is used at the top level. If such a declaration is used inside other constructs (e.g., the argument of `\AtBeginDocument`), blanks might survive, and in that case entries are not recognized.

capability allows the system maintainer to set up \LaTeX in the way best suited for the particular site.

The name of a size function consists of zero or more letters. Some of the size functions can take two arguments, one optional and one mandatory. Such an optional argument has to be enclosed in square brackets. For example, the specification

```
<-> s * [0.9] cmfib8
```

would select, for all possible sizes (we have the range 0 to ∞), the size function `s` with the optional argument 0.9 and the mandatory argument `cmfib8`. The `s` size function is a silent version “empty” one; i.e., it does not produce warnings and writes any information only to the `.log` file.

The size specifications in `\DeclareFontShape` are inspected in the order in which they are given. When a size info matches the requested user size, the corresponding size function is executed. If this process yields a valid font, no further entries are inspected. Otherwise, the search continues with the next entry.

The “empty” and “s” functions There are thirteen size functions defined in \LaTeX ; so far we have seen the “empty” and the `s` size function, which both expect an external font as argument (possibly with an additional scaling factor). Below we cover the important ones that deal with font substitution. For details on the others refer to [113], which is part of the \LaTeX distribution.

The “sub” and “ssub” functions The `sub` function is used to substitute a different font shape group if no external font exists for the current font shape group. In this case the argument is not an external font name but rather a different family, series, and shape combination separated by slashes (the encoding does not change for the reasons explained earlier). For example, in Latin Modern Typewriter there is no italic shape, only a slanted shape. Thus, it makes sense to declare the slanted shape as a substitute for the italic one (which is what the LM support files already do):

```
\DeclareFontShape{T1}{lmtt}{m}{it}{ <-> sub * lmtt/m/sl }{ }
```

Without this declaration, \LaTeX ’s automatic substitution mechanism (see Section 9.7.3) would substitute the default shape, Latin Modern Typewriter upright. A case for which you might want to add your own substitution, after looking at the LM Table 9.6 on page 687, is

```
\DeclareFontShape{T1}{lmdh}{bx}{sl}{ <-> ssub * lmdh/m/sl }{ }
```

because Latin Modern Dunhill has no bold or bold extended shapes at all. For this we used the `ssub` function that has the same functionality as the `sub` function but does not produce on-screen warnings (the first `s` means “silence”).

Font-loading options

As already mentioned, you need to declare each family using `\DeclareFontFamily`. The third argument to this command, as well as the last argument of the command `\DeclareFontShape`, can be used to specify special operations that are carried out when a font is loaded. In this way, you can change parameters that are associated with a font as a whole. You can also use `\DeclareFontFamily` to alter this information but only for fonts that have not been already loaded in memory!

For every external font, \LaTeX maintains, besides the information about each character, a set of global dimensions and other values associated with the font. For example, every font has its own “hyphen character”, the character that is inserted automatically when \LaTeX hyphenates a word. Another example is the normal width and the stretchability of a blank space between words (the “interword space”); again, a value is maintained for every font and changed whenever \LaTeX switches to a new font. By changing these values when a font is loaded, special effects can be achieved.

Normally, changes apply to a whole family; for example, you may want to prohibit hyphenation for all words typeset in the typewriter family. In this case, the third argument of `\DeclareFontFamily` should be used as we did earlier. If the changes should apply only to a specific font shape group, you must use the sixth argument of `\DeclareFontShape`. In other words, when a font is loaded, NFSS first applies the argument of `\DeclareFontFamily` and then the sixth argument of `\DeclareFontShape` so that it can override the load options specified for the whole family if necessary.

Below we study the information that can be set in this way (unfortunately, not everything is changeable) and discuss some useful examples. This part of the interface addresses very low-level commands of \TeX . Because it is so specialized, no effort was made to make the interface more \LaTeX -like. As a consequence, the methods for assigning integers and dimensions to variables are somewhat unusual.

*Changing the
hyphenation
character*

With `\hyphenchar\font=<number>`, \LaTeX specifies the character that is inserted as the hyphen when a word is hyphenated. The `<number>` represents the position of this character within the encoding scheme. The default is the value of `\defaultshyphenchar`, which is 45, representing the position of the “-” character in most encoding schemes. If this number is set to -1, hyphenation is suppressed. Thus, by declaring

```
\DeclareFontFamily{OT1}{cmtt}{\hyphenchar\font=-1}
```

you can suppress hyphenation for all fonts in the `cmtt` family with the encoding scheme `OT1`. Fonts with the `T1` encoding have an alternate hyphen character in position 127 so that you can set, for example,

```
\DeclareFontFamily{T1}{cmr}{\hyphenchar\font=127}
```

This makes the hyphen character inserted by \LaTeX different from the compound-word dash entered in words like “so-called”. \LaTeX does not hyphenate words that already contain explicit hyphen characters (except just after the hyphen), which can create a

real problem in languages in which the average word length is much larger than in English. With the above setting this problem can be solved because the dash is no longer the hyphen character.

Every \LaTeX font has an associated set of dimensions, which are changed by assignments of the form `\fontdimen<number>\font=<dimen>`, where `<number>` is the reference number for the dimension and `<dimen>` is the value to be assigned. The default values are taken from the `.tfm` file when the font is loaded. Each font has at least seven such dimensions:

- `\fontdimen1` Specifies the slant per point of the characters. If the value is zero, the font is upright.
- `\fontdimen2` Specifies the normal width of a space used between words (interword space).
- `\fontdimen3` Specifies the additional stretchability of the interword space — that is, the extra amount of white space that \LaTeX is allowed to add to the space between words to produce justified lines in a paragraph. In an emergency \LaTeX may add more space than this allowed value; in that case an “underfull box” is reported.
- `\fontdimen4` Specifies the allowed shrinkability of the interword space — that is, the amount of space that \LaTeX is allowed to subtract from the normal interword space (`\fontdimen2`) to produce justified lines in a paragraph. \LaTeX never shrinks the interword space to less than this minimum.
- `\fontdimen5` Specifies the x-height. It defines the font-oriented dimension 1 ex.
- `\fontdimen6` Specifies the quad width. It defines the font-oriented dimension 1 em.
- `\fontdimen7` Specifies the amount intended as extra space to be added after certain end-of-sentence punctuation characters when `\nonfrenchspacing` is in force. The exact rules for when \TeX uses this dimension (all or some of the extra space) are somewhat complex; see *The \TeX book* [84] for details. It is always ignored or rather replaced by the value `\xspaceskip`, when that value is nonzero.

When changing the interword spacing associated with a font, you cannot use an absolute value because such a value must be usable for all sizes within one font shape group. You must, therefore, define the value by using some other parameter that depends on the font. You could say, for example,

```
\DeclareFontShape{T1}{qtm}{m}{n}{<-> ec-qtmr}
    {\fontdimen2\font=.7\fontdimen2\font}
```

This declaration reduces the normal interword space to 70% of its original value. In a similar manner, the stretchability and shrinkability could be changed.

Some fonts used in formulas need more than seven font dimensions — namely, the symbol fonts called “symbols” and “largesymbols” (see Section 9.8.5). \TeX refuses to typeset a formula if these symbol fonts have fewer than 22 and 13 `\fontdimen`

parameters, respectively. The values of these parameters are used to position the characters in a math formula. An explanation of the meaning of every such `\fontdimen` parameter is beyond the scope of this book; details can be found in Appendix G of *The T_EXbook* [84] and the very interesting *TUGboat* article [73] by Bogusław Jackowski.

One unfortunate optimization is built into the T_EX system: T_EX loads every `.tfm` file only once for a given size. It is, therefore, impossible to define one font shape group (with the `\DeclareFontShape` command) to load some external font — say, `cmtt10` — and to use another `\DeclareFontShape` command to load the same external font, this time changing some of the `\fontdimen` parameters or some other parameter associated with the font. Trying to do so changes the values for both font shape groups.

Suppose, for example, that you try to define a Times Roman font shape with tight spacing by making the interword space smaller:

```
\DeclareFontShape{T1}{qtm}{m}{n}{<-> ec-qtmr}{}
\DeclareFontShape{T1}{qtm}{c}{n}{<-> ec-qtmr}
{\fontdimen2\font=.7\fontdimen2\font}
```

This declaration does not work. The interword spacing for the medium shape changes when the tight shape is loaded to the values specified there, and this result is not what is wanted. The best way to solve this problem is to define a virtual font that contains the same characters as the original font but differs in the settings of the font dimensions (see [75, 76, 93]). Another possible solution is to load the font at a slightly different size, as in the following declaration:

```
\DeclareFontShape{T1}{qtm}{c}{n}{<-> [0.9999] ec-qtmr}
{\fontdimen2\font=.7\fontdimen2\font}
```

That strategy makes them different fonts for T_EX with separate `\fontdimen` parameters. Alternatively, in this particular case you can control the interword space by setting `\spaceskip`, thereby overwriting the font values. See Section 3.1.1 for some discussion of that parameter.

9.8.2 Modifying font families and font shape groups

If you need a nonstandard font shape group declaration for a particular document, just place your private declaration in a package or the preamble of your document. It then overwrites any existing declaration for the font shape combination. Note, however, that the use of `\DeclareFontFamily` prevents a later loading of the corresponding `.fd` file (see Section 9.8.4). Also, your new declaration has no effect on fonts that are already loaded.¹

¹Today's L^AT_EX format preloads by default only a small number of fonts. However, by using the configuration file `preload.cfg`, more or fewer fonts can be loaded when the format is built. None of these preloaded fonts can be manipulated using font family or font shape declarations. Thus, if you want some special settings for the core fonts, you must ensure that none of these fonts is preloaded. For additional information on ways to customize a L^AT_EX installation, refer to the document

To get around both problems, you need to explicitly load the corresponding font definition files first by using `\LoadFontDefinitionFile`. Then you can call `\DeclareFamily` to overwrite the loading information or set up some special substitutions, etc. For example, to prevent hyphenation in Latin Modern Proportional Typewriter, where it is by default enabled, you could write

```
\LoadFontDefinitionFile{T1}{lmvtt}
\DeclareFamily{T1}{lmvtt}{\hyphenchar\font=-1}
```

The `\LoadFontDefinitionFile` command does nothing if the font definitions have already been loaded (by the kernel or by some package). The case that no font definition file exists for the combination is allowed as well. It can be identified by the fact that directly after the message “Trying to load . . .” in the transcript file there is no matching file load listed.

9.8.3 Declaring new font encoding schemes

Font changes that involve alterations in the encoding scheme require taking certain precautions. For example, in the T1 encoding, most accented letters have their own glyphs, whereas in the traditional \TeX text encoding (OT1), accented letters must be generated from accents and letters using the `\accent` primitive. (It is desirable to use glyphs for accented letters rather than employing the `\accent` primitive because, among other things, the former approach allows for correct hyphenation.) If the two approaches have to be mixed, perhaps because a font is available in only one of the encodings, the definition of a command such as `\` must behave differently depending on the current font encoding.

For this reason, each encoding scheme has to be formally introduced to \LaTeX with a `\DeclareFontEncoding` command, which takes three arguments. The first argument is the name of the encoding under which you access it using the `\fontencoding` command. Table 9.18 on page 737 provides a list of standard encoding schemes and their internal NFSS names.

The second argument contains any code (such as definitions) to be executed every time \LaTeX switches from one encoding to another using the `\fontencoding` command. The final argument contains code to be used whenever the font is accessed as a mathematical alphabet. Thus, these three arguments can be used to redefine commands that depend on the positions of characters in the encoding.

There should not be really any need for users (other than a handful for developers worldwide) to define new font encodings, so we do not provide further details here. If you are interested, refer to [113].

As we saw in Section 9.7.3 on font substitution, the default values for the family, series, and shape may need to differ across encodings. To support this, NFSS provides the command `\DeclareFontSubstitution`, which again takes the encoding as the first argument. The next three arguments are the default values (associated with this encoding) for family, series, and shape for use in the automatic substitution

`cfpguide.pdf` [110], which is part of the \LaTeX distribution.

process, as explained in Section 9.7.3. It is important that these arguments form a valid font shape — in other words, that a `\DeclareFontShape` declaration exists for them. Otherwise, an error message is issued when NFSS checks its internal tables at `\begin{document}`.

9.8.4 Internal file organization

Font families can be declared when a format file is generated, declared in the document preamble, or loaded on demand when a font change command in the document requests a combination that has not been used so far. The first option consumes internal memory in every \LaTeX run, even if the font is not used. The second and third possibilities take a little more time during document formatting, because the font definitions have to be read during processing time. Nevertheless, it is preferable to use the latter solutions for most font shape groups, because it allows you to typeset a wide variety of documents with a single \LaTeX format.

When the format is generated, \LaTeX reads a file named `fonttext.ltx` that contains the standard set of font family definitions and some other declarations related to text fonts. With some restrictions,¹ this set can be altered by providing a configuration file `fontdef.cfg`; see the documentation [110].

All other font family definitions should be declared in external files loaded on request: either package files or font definition (`.fd`) files. If you place font family definitions in a package file, you must explicitly load this package after the `\documentclass` command. There is also a third possibility: whenever NFSS gets a request for a font family `foo` in an encoding scheme `BAR` and it has no knowledge about this combination, it tries to load a file called `barfoo.fd` (all letters lowercase). If this file exists, it is supposed to contain font shape group definitions for the family `foo` in the encoding scheme `BAR` — that is, declarations of the form

```
\DeclareFontFamily{BAR}{foo}{..}
\DeclareFontShape{BAR}{foo}{..}{..}{..}{..}
...
\endinput
```

In this way it becomes possible to declare a huge number of font families for \LaTeX without filling valuable internal memory with information that is almost never used.

Each `.fd` file should contain all font definitions for one font family in one encoding scheme. It should consist of one or more `\DeclareFontShape` declarations and exactly one `\DeclareFontFamily` declaration. Other definitions should not appear in the file, except perhaps for a `\ProvidesFile` declaration or some `\typeout` statement informing the user about the font loading.

An unfortunately common mistake still found in some of the existing `.fd` files is the definition of additional helper commands using `\newcommand` or `\def`. Because an `.fd` file may get loaded at random points during the document processing, it is

Any definitions in
.fd files have to
be global!

¹Any such customization should not be undertaken lightly as it is unfortunately very easy to produce a \LaTeX format that shows subtle or even glaring incompatibilities with other installations.

not impossible that this happens inside a group. In this case, these helper commands get undefined at the end of the group, resulting in puzzling errors later.

New encoding schemes cannot be introduced via the `.fd` mechanism. NFSS rejects any request to switch to an encoding scheme that was not explicitly declared in the \LaTeX format (i.e., `fonttext.ltx`), in a package file, or in the preamble of the document.

Unicode engines

Fonts for Unicode engines usually do not use `.fd` files. Instead, they are loaded through the interfaces provided by the `fontspec` package that was discussed in Section 9.6. What happens behind the scenes is that `fontspec` generates the necessary `\DeclareFontFamily` and `\DeclareFontShape` declarations on the fly.

9.8.5 Declaring new fonts and symbols for use in math

Setting up additional math fonts is also an activity that is not often needed; however, because there is the occasional need for it, this section provides you with the necessary information.

Specifying font sizes

For every text size, NFSS maintains three sizes that are used to typeset formulas (see also Section 11.7.1): the size in which to typeset most of the symbols (selected by `\textstyle` or `\displaystyle`); the size for first-order subscripts and superscripts (`\scriptstyle`); and the size for higher-order subscripts and superscripts (`\scriptscriptstyle`). If you switch to a new text size, for which the corresponding math sizes are not yet known, NFSS tries to calculate them as fractions of the text size. Instead of letting NFSS do the calculation, you might want to specify the correct values yourself via `\DeclareMathSizes`. This declaration takes four arguments: the outer text size and the three math sizes for this text size. For example, the class file for *The \LaTeX Companion* contains settings like the following:

```
\DeclareMathSizes{14}{14}{10}{7}
\DeclareMathSizes{36}{ }{ }{ }
```

The first declaration defines the math sizes for the 14pt heading size to be 14pt, 10pt, and 7pt, respectively. The automatic calculation would have made the scriptfont $14 \times 0.7 = 9.8$ instead.

The second declaration (the size for the chapter headings) informs NFSS that no math sizes are necessary for 36pt text size. This avoids the unnecessary loading of more than 30 additional fonts. For the first edition of *The \LaTeX Companion* such declarations were very important to be able to process the book with all its examples as a single document (the book loaded 228 fonts out of a maximum of 255). Today, \TeX installations are usually compiled with much larger internal tables (e.g., the laptop implementation used to write this chapter allows 9000 fonts), so conserving space

	'0	'1	'2	'3	'4	'5	'6	'7	
'00x	\neq	\neq	\neq	\neq	\neq	\neq	\neq	\neq	"0x
'01x	\neq	\neq	\neq	\neq	\neq	\neq	\neq	\neq	
'02x	\neq	\neq	\neq	\neq	\neq	\neq	\neq	\neq	"1x
'03x	\neq	\neq	\neq	\neq	\neq	\neq	\neq	\neq	
'04x	\neq	\neq	\neq	\neq	\neq	\neq	\neq	\neq	"2x
'05x	\neq	\neq	\neq	\neq	\neq	\neq	\neq	\neq	
'06x	\neq	\neq	\neq	\neq	\neq	\neq	\neq	\neq	"3x
'07x	\neq	\neq	\neq	\neq	\neq	\neq	\neq	\neq	
'10x	\neq	A	B	C	D	E	F	G	"4x
'11x	H	I	J	K	L	M	N	O

'14x	\neq	\neq					\neq	\neq	"6x
'15x	\neq	\neq	\neq	\neq	\neq	\neq	\neq	\neq	
'16x	\neq	\neq	\neq	\neq	\neq	\neq	\neq	\neq	"7x
'17x	\neq	\neq	\neq	\neq	\neq	\neq	\neq	\neq	
	"8	"9	"A	"B	"C	"D	"E	"F	

Table 9.19: Glyph chart for msbm10 produced by the nfssfont.tex program

is no longer a major concern. In any event, you should be careful about disabling math sizes, because if some formula is typeset in such a size after all, it is typeset in whatever math sizes are still in effect from an earlier text size.

Adding new symbol fonts

We have already seen how to use math alphabet commands to produce letters with special shapes in a formula. We now discuss how to add fonts containing special symbols, called “symbol fonts”, and how to make such symbols accessible in formulas.

The process of adding new symbol fonts is similar to the declaration of a new math alphabet identifier: `\DeclareSymbolFont` defines the defaults for all math versions, and `\SetSymbolFont` overrides the defaults for a particular version.

The math symbol fonts are accessed via a symbolic name, which consists of a string of letters. If, for example, you want to install the AMS fonts msbm10, shown in Table 9.19, you first have to make the typeface known to NFSS using the declarations described in the previous sections. These instructions would look like

```
\DeclareFontFamily{U}{msb}{}
```

Type	Meaning	Example	Type	Meaning	Example
<code>\mathord</code>	Ordinary	<code>/</code>	<code>\mathopen</code>	Opening	<code>(</code>
<code>\mathop</code>	Large operator	<code>\sum</code>	<code>\mathclose</code>	Closing	<code>)</code>
<code>\mathbin</code>	Binary operation	<code>+</code>	<code>\mathpunct</code>	Punctuation	<code>,</code>
<code>\mathrel</code>	Relation	<code>=</code>	<code>\mathalpha</code>	Alphabet character	<code>A</code>

Table 9.20: Math symbol type classification

```
\DeclareFontShape{U}{msb}{m}{n}{<5> <6> <7> <8> <9> gen * msbm
<10> <10.95> <12> <14.4> <17.28> <20.74> <24.88> msbm10}{}
```

and are usually placed in an `.fd` file. You then have to declare that symbol font for all math versions by issuing the command

```
\DeclareSymbolFont{AMSb}{U}{msb}{m}{n}
```

It makes the font shape group `U/msb/m/n` available as a symbol font under the symbolic name `AMSb`. If there were a bold series in this font family (unfortunately there is not), you could subsequently change the setup for the bold math version by writing

```
\SetSymbolFont{AMSb}{bold}{U}{msb}{b}{n}
```

After taking care of the font declarations, you can make use of this symbol font in math mode. But how do you tell NFSS that `$a\lessdot b$` should produce $a < b$, for example? To do so, you have to introduce your own symbol names to NFSS, using `\DeclareMathSymbol`.

```
\DeclareMathSymbol{cmd}{type}{symbol-font}{slot}
```

The first argument to `\DeclareMathSymbol` is your chosen command name. The second argument is one of the commands shown in Table 9.20 and describes the nature of the symbol — whether it is a binary operator, a relation, and so forth. \TeX uses this information to leave the correct amount of space around the symbol when it is encountered in a formula. Incidentally, except for `\mathalpha`, these commands can be used directly in math formulas as functions with one argument, in which case they space their (possibly complex) argument as if it were of the corresponding type; see Section 11.8 on page 208.

The third argument identifies the symbol font from which the symbol should be fetched — that is, the symbolic name introduced with the `\DeclareSymbolFont` command. The fourth argument gives the symbol's position in the font encoding, either as a decimal, octal, or hexadecimal value. Octal (base 8) and hexadecimal (base

16) numbers are preceded by ' and ", respectively. If you look at Table 9.19 on page 750, you can easily determine the positions of all glyphs in this font. Such tables can be printed using the \LaTeX program `nfssfont.tex`, which is part of the \LaTeX distribution; see Section 9.5.9 on page 705. For example, `\lessdot` would be declared using

```
\DeclareMathSymbol{\lessdot}{\mathbin}{AMSb}{"6C}
```

Instead of a command name, you can use a single character in the first argument. For example, the `eulervm` package has several declarations of the form

```
\DeclareMathSymbol{0}{\mathalpha}{letters}{"30}
```

that specify where to fetch the digits from.

Because `\DeclareMathSymbol` is used to specify a position in some symbol font, it is important that all external fonts associated with this symbol font via the `\DeclareSymbolFont` and `\SetSymbolFont` commands have the same character in that position. The simplest way to ensure this uniformity is to use only fonts with the same encoding (unless it is the U, a.k.a. unknown, encoding, because two fonts with this encoding are not required to implement the same characters).

Besides `\DeclareMathSymbol`, \LaTeX knows about `\DeclareMathAccent`, `\DeclareMathDelimiter`, and `\DeclareMathRadical` for setting up math font support. Details about these slightly special declarations can be found in [113], which is part of every \LaTeX distribution.

*Be careful with
fonts that contain
both math alphabets
and act as symbol
fonts*

If you look again at the glyph chart for `msbm10` (Table 9.19 on page 750), you will notice that this font contains “blackboard bold” letters, such as $\mathbb{A}\mathbb{B}\mathbb{C}$. If you want to use these letters as a math alphabet, you can define them by using a `\DeclareMathAlphabet` declaration, but given that this symbol font is already loaded to access individual symbols, it is better to use a shortcut:

```
\DeclareSymbolFontAlphabet{\mathbb}{AMSb}
```

That is, you give the name of your math alphabet identifier and the symbolic name of the previously declared symbol font.

An important reason for not unnecessarily loading symbol fonts twice is that there is an upper limit of 16 math fonts that can be active at any given time in \LaTeX . In calculating this limit, each symbol font counts; math alphabets count only if they are actually used in the document, and they count locally in each math version. Thus, if eight symbol fonts are declared, you can use a maximum of eight (possibly different) math alphabet identifiers within every version.¹

To summarize: to introduce new symbol fonts, you need to issue a small number of `\DeclareSymbolFont` and `\SetSymbolFont` declarations and a potentially large number of `\DeclareMathSymbol` declarations; hence, adding such fonts is best done in a package file.

¹By default two math fonts remain local per formula if used for math alphabets and not for symbol fonts. They can then be reassigned anew each time. This default can be enlarged; see page 681.

Introducing new math versions

We have already mentioned that the standard setup automatically declares two math versions, normal and bold. To introduce additional versions, you use the declaration `\DeclareMathVersion`, which takes one argument, the name of the new math version. All symbol fonts and all math alphabets previously declared are automatically available in this math version; the default fonts are assigned to them — that is, the fonts you have specified with `\DeclareMathAlphabet` or `\DeclareSymbolFont`.

You can then change the setup for your new version by issuing appropriate `\SetMathAlphabet` and `\SetSymbolFont` commands, as shown in previous sections (pages 683 and 751) for the bold math version. Again, the introduction of a new math version is normally done in a package file.

Changing the symbol font setup

Besides adding new symbol fonts to access more symbols, the commands we have just seen can be used to change an existing setup. This capability is of interest if you choose to use special fonts in some or all math versions.

The default settings in \LaTeX are given here:

```
\DeclareMathVersion{normal} \DeclareMathVersion{bold}

\DeclareSymbolFont{operators}      {OT1}{cmr}{m}{n}
\DeclareSymbolFont{letters}        {OML}{cmm}{m}{it}
\DeclareSymbolFont{symbols}        {OMS}{cmsy}{m}{n}
\DeclareSymbolFont{largesymbols}   {OMX}{cmex}{m}{n}

% Special bold fonts only for these:
\SetSymbolFont {operators}{bold}{OT1}{cmr}{bx}{n}
\SetSymbolFont {letters}  {bold}{OML}{cmm}{b}{it}
```

In the standard setup, digits and text produced by “log-like operators”, such as `\log` and `\max`, are taken from the symbol font called `operators`. To change this situation so that these elements agree with the main text font — say, Computer Modern Sans rather than Computer Modern Roman — you can issue the following commands:

```
\SetSymbolFont{operators}{normal}{OT1}{cmss}{m}{n}
\SetSymbolFont{operators}{bold}  {OT1}{cmss}{bx}{n}
```

Symbol fonts with the names `symbols` and `largesymbols` play a unique rôle in \TeX , and for this reason they need a special number of `\fontdimen` parameters associated with them. Thus, only specially prepared fonts can be used for these two symbol fonts. In principle one can add such parameters to any font at load time by using the third parameter of `\DeclareFontFamily` or the sixth parameter of `\DeclareFontShape`. Information on the special parameters for these symbol fonts can be found in Appendix G of [84].

9.9 L^AT_EX's encoding models

For most users it is probably sufficient to know that there exist certain input and output encodings and to have some basic knowledge about how to use them, as described in the previous sections. However, sometimes it is helpful to know the whole story in some detail, either to set up a new encoding or to better understand packages or classes that implement special features. So here is everything you always wanted to know about encodings in L^AT_EX.

We start by describing the general character data flow within the L^AT_EX system, deriving from that the base requirements for various encodings and the mapping between them. We then have a closer look at the internal representation model for character data within L^AT_EX, followed by a discussion of the mechanisms used to map incoming data via input encodings into that internal representation.

Finally, we explain how the internal representation is translated, via the output encodings, into the form required for the actual task of typesetting.

9.9.1 Character data within the L^AT_EX system

Document processing with the L^AT_EX system starts by interpreting data present in one or more source files. These data, which represent the document content, are stored in these files in the form of octets representing characters. To correctly interpret these octets, L^AT_EX (or any other program used to process the file, such as an editor) must know the encoding that was used when the file was written. In other words, it must know the mapping between abstract characters and the octets representing them.

With an incorrect mapping, all further processing is flawed to some extent unless the file contains only characters of a subset common in both encodings.¹

L^AT_EX makes one fundamental assumption at this stage: that (nearly) all characters of visible ASCII (decimal 32–126) are represented by the number that they have in the ASCII code table; see Table 9.21 on the next page.

There is both a practical and a T_EXnical reason for this assumption. The practical reason is that most 8-bit encodings as well as the UTF-8 encoding usually used today share a common 7-bit plane. The T_EXnical reason is that for using T_EX efficiently, the majority of the visible portion of ASCII needs to be processed as characters of category “letter” (because only characters with this category can be used in multiple-character command names in T_EX) or of category “other” (because T_EX will not, for example, recognize the decimal digits as being part of a number if they do not have this category code).²

¹Because most encodings in the Western world (including the UTF-8 encoding) share as a common subset a large fraction of the ASCII code (i.e., most of the 7-bit plane), documents consisting mainly of unaccented Latin characters are still understandable if viewed or processed in an encoding different from the one in which they were originally written. However, the more characters outside visible ASCII are used, the less comprehensible the text becomes. A text can become completely unintelligible when, for instance, Greek or Russian documents written in an 8-bit encoding are reprocessed in any other 8-bit encoding (or in UTF-8).

²At least this was true when this interface was being designed. These days, with computers being much faster than before, it would probably be possible to radically change the input method of T_EX by

Represented as Characters	
Digits:	0 1 2 3 4 5 6 7 8 9
Lowercase letters:	a b c d e f g h i j k l m n o p q r s t u v w x y z
Uppercase letters:	A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
Punctuation:	. , ; : ? ! ' '
Miscellaneous symbols:	* + - = () [] / @
Not Represented as Characters	
T _E X syntax characters:	\$ ^ _ { } # & % \ ~
Missing in (some) OT1 fonts	< > "

Table 9.21: LICR objects represented with single characters

When a character — or more exactly an 8-bit number in pdfT_EX — is declared to be of category “letter” or “other” in T_EX, then this character is transparently passed through T_EX. This means that in the output T_EX typesets whatever symbol is in the font at the position addressed by that number.

Unicode engines

The same is true for Unicode engines, except that in those engines characters mean Unicode characters and therefore cover a much larger range. This is why, for example, “ä” is a real character in these engines and can therefore appear, say, in command names, while in pdfT_EX it is seen as two separate bytes, i.e., two characters. Thus, to interpret UTF-8 in pdfT_EX, the first byte is defined to be “active” and not of type “letter”. This then assembles the intended character by reading further bytes and eventually generates \“a to represent the “ä”.

A consequence of the assumption mentioned earlier is that fonts intended to be used for general text require that (most of) the visible ASCII characters are present in the font and are encoded according to the ASCII encoding. The exact list is given in Table 9.21.

All other 8-bit numbers (i.e., those outside visible ASCII) potentially being present in the input file are assigned a category code of “active”, which makes them act like commands inside T_EX. This allows L^AT_EX to transform them via the input encodings to a form that we call the L^AT_EX internal character representation (LICR).

The most important characteristic of objects in the LICR is that the representation is 7-bit ASCII making it invariant to any input encoding change, because all input encodings are supposed to be transparent with respect to visible ASCII. This enables L^AT_EX, for example, to write auxiliary files (e.g., .toc files) using the LICR representation and to read them back in a different context (and possibly different encoding) without any misinterpretations.

Unicode’s UTF-8 encoding is handled similarly in pdfT_EX: the ASCII characters represent themselves, and the starting octets for multiple-byte representations act as basically disabling it altogether and parsing the input data manually — that is, character by character.

active characters that scan the input for the remaining octets. The result is turned into an object in the LICR, if it is mapped, or it generates an error, if the given Unicode character is not mapped. However, if UTF-8 is used as input encoding, the characters are written out not in their LICR form but again as UTF-8 characters. Thus, in `.toc` files, etc., you see “Grüße” and not “Gr\“u\ss e” if that input encoding is in force.

The purpose of the output (or font) encoding is then to map the internal character representations to glyph positions in the current font used for typesetting or, in some cases, to initiate more complex actions. For example, it might place an accent (present in one position in the current font) over some glyph (in a different position in the current font) to achieve a printed image of the abstract character represented by the command(s) in the internal character encoding.

Because the LICR encodes all possible characters addressable within \LaTeX , it is far larger than the number of characters that can be represented by a single \TeX font in pdf\TeX (which can contain a maximum of 256 glyphs). In some cases a character not present in a font can be rendered by combining glyphs, such as the accented characters mentioned above. However, when the character requires a special shape (e.g., the currency symbol “ $\text{\textcircled{C}}$ ”), there is no way to fake it if that glyph does not exist in the font.

Nevertheless, for text symbols (that do not participate in hyphenation) the \LaTeX model for character encoding supports automatic mechanisms for fetching glyphs from different fonts so that such characters if missing in the current font get typeset — provided a suitable additional font containing them is available, of course.

Unicode engines

The situation in Unicode engines is quite different, because fonts for these engines can contain arbitrarily many characters. This is why in those engines \LaTeX normally uses only a single font encoding (TU), and instead of passing through an LICR representation, the UTF-8 characters represent themselves and do not change their behavior if the output encoding is changed. For example, the input string `Grüße` correctly generates “Grüße” if a Unicode font is used, but if we try

```
\fontencoding{OT1}\fontfamily{cmr}\selectfont  Grüße
\fontencoding{T1}\fontfamily{cmr}\selectfont    Grüße
```

in such an engine, the result would be

Gre GrüsSe

because the characters “ü” and “ß” have the Unicode numbers 00FC and 00DF, respectively, and in OT1 there are not any glyphs in slots greater than 007F (and thus neither character is typeset) and in T1 the “ü” happens to be in its Unicode slot, but “ß” is not, so we get a wrong glyph typeset.

However, if LICR representations are used in the input, e.g., `\“u` or `\ss`, they are interpreted correctly in all engines so that old documents work correctly when processed.

9.9.2 L^AT_EX's internal character representation (LICR)

In this section we cover the LICR concepts in some more depth. Technically speaking, text characters are represented internally by L^AT_EX in one of three ways, each of which is discussed in the following sections.

Representation as characters

If pdfT_EX is used, then only a small number of characters are represented by “themselves”; for example, the Latin A is represented as the character “A”. Characters represented in this way are shown in Table 9.21 on page 755. They form a subset of visible ASCII, and inside T_EX all of them are given the category code of “letter” or “other”. Some characters from the visible ASCII range are not represented in this way, either because they are part of the T_EX syntax¹ or because they are not present in all fonts. If one uses, for example, “<” in text, the current font encoding determines whether one gets < (T1) or perhaps a j (OT1) in the printout.²

Unicode engines

In contrast to pdfT_EX nearly all characters are represented by themselves in Unicode engines: essentially all UTF-8 characters except for those that are used by T_EX for syntax purposes.

Representation with character sequences

T_EX's internal ligature mechanism supports the generation of new characters from a sequence of input characters. While this is actually a property of the font, some such sequences have been explicitly designed to serve as input shortcuts for characters that are otherwise difficult to type with most keyboards. Only a very few characters generated in this way are considered to belong to L^AT_EX's internal representation. These include the en-dash and em-dash, which are generated by the ligatures -- and ---, and the opening and closing double quotes, which are generated by ‘ ‘ and ’ ’ (for the latter people sometimes use the single character " , but this is incorrect because it may produce a straight double quote, i.e., "). While most fonts also implement ! ‘ and ? ‘ to generate j and i, this feature is not universally available in all fonts. For this reason *all* such characters have an alternative internal representation as a command (e.g., \textendash or \textexclamdown).

Unicode engines

Because this form of representation has been available for basically every font usable with pdfT_EX, it has also been implemented for Unicode engines (technically through some engine-specific code when loading fonts as it is not an OpenType font feature).

¹The L^AT_EX syntax knows a few more characters, such as *[] . They play a dual rôle, also being used to represent the characters in straight text. Sometimes problems arise trying to keep the two meanings apart. For example, a] within an optional argument is possible only when it is hidden by a set of braces; otherwise, L^AT_EX thinks the optional argument has ended.

²This describes the situation in text. In math “<” has a well-defined meaning: “generate a less than relation symbol”.

Representation as “font-encoding-specific” commands

The other way to represent characters internally in \LaTeX (and this covers the majority of characters when \pdfTeX is used) is with special \LaTeX commands (or command sequences) that remain unexpanded when written to a file or when placed into a moving argument. These special commands are sometimes referred to as “font-encoding-specific commands” because their meaning depends on the font encoding current when \LaTeX is ready to typeset them. Such commands are declared using special declarations, as discussed below. They usually require individual definitions for each font encoding. If no definition exists for the current encoding, either a default is used (if available) or an error message is presented to the user.

Technically, when the font encoding is changed at some point in the document, the definitions of the encoding-specific commands do not change immediately, because that would mean changing a large number of commands on the spot. Instead, these commands have been implemented in such a way that they notice, once they are used, if their current definition is no longer suitable for the font encoding in force. In such a case they call upon their counterparts in the current font encoding to do the actual work.

The set of “font-encoding-specific commands” is not fixed, but rather implicitly defined to be the union of all commands defined for individual font encodings. Thus, by adding new font encodings to \LaTeX , new “font-encoding-specific commands” might emerge.

Unicode engines

With Unicode engines most characters are transparently handled, so encoding-specific commands are normally not needed; it is nevertheless possible to use them in the input. This makes it easy to reuse documents, originally written for \pdfTeX , in Unicode engines.

9.9.3 Input encodings

Since 2015 the default input encoding for \LaTeX is UTF-8 unless explicitly changed in the preamble using the `inputenc` package. This means that in \pdfTeX all UTF-8 characters that can be typeset using the loaded fonts can nowadays be entered in the source document in their natural UTF-8 form, e.g., as “ü” or “ß”, and there is no need to use the LICR representations `\u` or `\ss` for them. This is technically achieved in \pdfTeX by mapping the UTF-8 characters to their corresponding LICR objects using `\DeclareUnicodeCharacter` declarations.

```
\DeclareUnicodeCharacter{hex-number}{LICR-object}
```

Unusual  argument syntax

This declaration maps a Unicode number (represented as a *hex-number* without a preceding “”) to an *LICR-object*. For example,

```
\DeclareUnicodeCharacter{00A3}{\textsterling}
\DeclareUnicodeCharacter{011A}{\v E}
\DeclareUnicodeCharacter{2031}{\textpertenthousand}
```

Unicode characters in the range of 0000 to 007F (i.e., the ASCII part of Unicode) cannot be declared with this command: if you try, L^AT_EX responds with an error message.

In theory, there should be only a single unique bidirectional mapping between the two name spaces so that all such declarations could be already available when L^AT_EX starts. In practice, the situation is a little more complicated. For one, it is not sensible to automatically provide the whole table, because that would require a huge amount of T_EX's memory. Additionally, there are many Unicode characters for which no LICR object exists (so far), and conversely some LICR objects have no equivalents in Unicode.¹ This problem is solved in L^AT_EX by loading only those Unicode mappings that correspond to the encodings used in a particular document (as far as they are known) and responds to any other request for a Unicode character with a suitable error message. It then becomes your task to either provide the right mapping information or, if necessary, load an additional font encoding.

For each output encoding, there should exist a file `<encoding>enc.dfu` containing all necessary mapping declarations (like those above) that correspond to this particular encoding. When an encoding is loaded with `fontenc`, this file is read in, and afterwards its declarations are available.

Because different font encodings often provide to a certain extent the same characters, it is quite common for declarations for the same Unicode character to be found in different `.dfu` files. It is, therefore, very important that these declarations in different files be identical (which in theory they should be anyway, but...). Otherwise, the declaration loaded last survives, which may be a different one from document to document.²

Of course, `\DeclareUnicodeCharacter` can also be used in the preamble if a mapping is missing or needs changing for some reason.

Legacy 8-bit input encodings

To process files stored in one of the legacy 8-bit input encodings L^AT_EX offers the package `inputenc`. Once this package is loaded (with or without options), the two declarations `\DeclareInputText` and `\DeclareInputMath` for mapping 8-bit input characters to LICR objects become available. Their usage should be confined to input encoding files, packages, or, if necessary, to the preamble of documents. Input encoding files use the name of the encoding in lowercase letters and the extension `.def`, e.g., `latin1.def`.

Because documents today are stored by default in UTF-8, there is seldom a need for using `inputenc`, and we refer to the package documentation for technical details of how input encoding files are set up or altered through the above commands.

¹This is perhaps a surprising statement, but simply consider that, for example, accent commands like `\`` combined with some other character form a new LICR object, such as `\`d` (whether sensible or not). Many such combinations are not available in Unicode.

²So anyone who wants to provide a new `.dfu` file for some encoding that was previously not covered should carefully check the existing definitions in `.dfu` files for related encodings. Standard files provided with `inputenc` are guaranteed to have uniform definition — they are, in fact, all generated from a single list that is suitably split up. A full list of currently existing mappings can be found in the file `utf8enc.dfu`.

9.9.4 Output encodings

As we learned earlier, output encodings define the mapping from the LICR to the glyphs (or constructs built from glyphs) available in the fonts used for typesetting. These mappings are referenced inside \LaTeX by two- or three-letter names (e.g., OT1 or T2A). We say that a certain font is in a certain encoding if the mapping corresponds to the positions of the glyphs in the font in question. So what are the exact components of such a mapping?

*Pass-through
characters*

Characters internally represented by ASCII characters are simply passed on to the font. In other words, \TeX uses the ASCII code to select a glyph from the current font. For example, the character “A” with ASCII code 65 results in typesetting the glyph in position 65 in the current font. This is why \LaTeX requires that fonts for text contain all such ASCII letters in their ASCII code positions, because there is no way to interact with this basic \TeX mechanism (other than to disable it and do everything “manually”). Thus, for visible ASCII, a one-to-one mapping is implicitly present in all output encodings.

Unicode engines

In the case of the TU encoding used by Unicode engines, essentially all UTF-8 letters are passed on to the font. However, the other means of referring to glyphs (i.e., sequences of characters or the font-encoding-specific commands discussed below) are also supported.

*Characters
represented by
ASCII sequences*

Characters internally represented as sequences of ASCII characters (e.g., “--”) are handled as follows: when the current font is first loaded, \TeX is informed that the font contains a number of so-called ligature programs. These define certain character sequences that are not to be typeset directly but rather to be replaced¹ by some other glyphs from the font (the exact position of each replacement glyph is font dependent and not important otherwise). For example, when \TeX sees “--” in the input (i.e., ASCII code 45 twice), a ligature program might direct it to use the glyph in position 123 instead (which then would hold the glyph “-”). No interaction with this mechanism is possible. Some such ligatures are present for purely aesthetic reasons and may or may not be available in certain fonts (e.g., `ff` generating “ff” rather than “ff”). Others are supposed to be implemented for a certain encoding (e.g., “---” producing an `\emdash`).

*Characters
represented as font-
encoding-specific
commands*

Nevertheless, the bulk of the internal character representation consists of “font-encoding-specific” commands. They are mapped using the declarations described below. All declarations have the same structure in their first two arguments: the font-encoding-specific command (or the first component of it, if it is a command sequence), followed by the name of the encoding. Any remaining arguments depend on the type of declaration.

Thus, an encoding XYZ is defined by a collection of declarations all having the name XYZ as their second argument. Of course, to be of any use, some fonts must be encoded in that encoding. In fact, the development of font encodings is normally done the other way around — namely, someone starts with an existing font and then

¹The actions carried out by a font ligature program can, in fact, be far more complex, but for the purpose of our discussion here this simplified view is appropriate. For an in-depth discussion, see Knuth’s paper on virtual fonts [93].

provides appropriate declarations for using it. This collection of declarations is then given a suitable name, such as OT1. In the next section, we take the font `ec-lmr10`, shown in Table 9.22 on page 763, whose font encoding is called T1 in L^AT_EX, and build appropriate declarations to access the glyphs from a font encoded in this way. The blue characters in this table are those that have to be present in the same positions in every text encoding, because they are transparently passed through T_EX.

Declarations for output encoding files

Like input encoding files, output encoding files are identified by the extension `.def`. However, the base name of the file is slightly more structured: the name of the encoding in lowercase letters, followed by the letters `enc` (e.g., `t1enc.def` for the T1 encoding).

Such files should contain only the declarations described in the current section. Because output encoding files might be read several times by L^AT_EX, it is particularly important to adhere to this rule strictly and to refrain from using, for example, `\newcommand`, which prevents reading such a file multiple times!

For identification purposes an output encoding file should start with a `\ProvidesFile` declaration describing the nature of the file. For example:

```
\ProvidesFile{t1enc.def}[2001/06/05 v1.94 Standard LaTeX file]
```

To be able to declare any encoding-specific commands for a particular encoding, we first have to make this encoding known to L^AT_EX. This is achieved via the `\DeclareFontEncoding` declaration. At this point¹ it is also useful to declare the default substitution rules for the encoding with the help of the command `\DeclareFontSubstitution`; both declarations are described in detail in Section 9.8.3 starting on page 747.

```
\DeclareFontEncoding{T1}{}{}
\DeclareFontSubstitution{T1}{cmr}{m}{n}
```

Having introduced the T1 encoding in this way to L^AT_EX, we can now proceed with declaring how font-encoding-specific commands should behave in that encoding.

```
\DeclareTextSymbol{LICR-object}{encoding}{slot}
```

Perhaps the simplest form of declaration is the one for text symbols, where the internal representation can be directly mapped to a single glyph in the target font. This is handled by the `\DeclareTextSymbol` declaration, whose third argument — the font position — can be given as a decimal, hexadecimal, or octal number. For example,

```
\DeclareTextSymbol{\ss}{T1}{255}
\DeclareTextSymbol{\AE}{T1}{'306} % font position as octal number
\DeclareTextSymbol{\ae}{T1}{"E6}  % ... as hexadecimal number
```

¹This should happen in the encoding `(enc)enc.def` file and *not* in a font `.fd` file!

declare that the font-encoding-specific commands `\ss`, `\AE`, and `\ae` should be mapped to the font (decimal) positions 255, 198, and 230, respectively, in a T1-encoded font. As mentioned earlier, it is safest to use decimal notation in such declarations, even though octal or hexadecimal values are often easier to identify in glyph charts like the one on the next page. Mixing them like we did in the example above is certainly bad style. All in all, there are 49 such declarations for the T1 encoding.

```
\DeclareTextAccent{LICR-accent}{encoding}{slot}
```

Often fonts contain diacritical marks as individual glyphs to allow the production of accented characters by combining such a diacritical mark with some other glyph. Such accents (as long as they are to be placed on top of other glyphs) are declared using the `\DeclareTextAccent` command; the third argument *slot* is the position of the diacritical mark in the font. For example,

```
\DeclareTextAccent{"}{T1}{4}
```

defines the “umlaut” accent. From that point onward, an internal representation such as `\"a` has the following meaning in the T1 output encoding: typeset “ä” by placing the accent in position 4 over the glyph in position 97 (the ASCII code of the character a). In fact, such a declaration implicitly defines a huge range of internal character presentations — that is, anything of the type `\"⟨base-glyph⟩`, where *⟨base-glyph⟩* is something defined via `\DeclareTextSymbol` or any ASCII character belonging to the LICR, such as “a”.

Even those combinations that do not make much sense, such as `\"P` (i.e., pilcrow sign with umlaut ¶) conceptually become members of the set of font-encoding-specific commands in this way. There are a total of 11 such declarations in the T1 encoding.

```
\DeclareTextComposite
    {LICR-accent}{encoding}{simple-LICR-object}{slot}
```

The glyph chart on the facing page contains a large number of accented characters as individual glyphs — for example, “ä” in position '344 octal. Thus, in T1 the encoding-specific command `\"a` should not result in placing an accent over the character “a” but instead should directly access the glyph in that position of the font. This is achieved by the declaration

```
\DeclareTextComposite{"}{T1}{a}{228}
```

which states that the encoding-specific command `\"a` results in typesetting the glyph 228, thereby disabling the accent declaration above. For all other encoding-specific commands starting with `\"`, the accent declaration remains in place. For example, `\"b` produces a “b̈” by placing an accent over the base character b.

The third argument, *simple-LICR-object*, should be a single letter, such as “a”, or a single command, such as `\j` or `\oe`. There are 110 such composites declared for the T1 encoding.

	'0	'1	'2	'3	'4	'5	'6	'7	
'00x	`	'	^	~	..	"	°	˘	"0x
'01x	˘	–	•	˙	˚	,	‹	›	
'02x	“	”	„	«	»	—	—		
'03x	o	ı	j	ff	fi	fl	ffi	ffl	"1x
'04x	□	!	"	#	\$	%	&	'	
'05x	()	*	+	,	-	.	/	"2x
'06x	0	1	2	3	4	5	6	7	
'07x	8	9	:	;	<	=	>	?	"3x
'10x	@	A	B	C	D	E	F	G	
'11x	H	I	J	K	L	M	N	O	"4x
'12x	P	Q	R	S	T	U	V	W	
'13x	X	Y	Z	[\]	^	—	"5x
'14x	‘	a	b	c	d	e	f	g	
'15x	h	i	j	k	l	m	n	o	"6x
'16x	p	q	r	s	t	u	v	w	
'17x	x	y	z	{		}	~	-	"7x
'20x	Ă	Ą	Ć	Č	Ď	Ě	Ę	Ğ	
'21x	Ł	Ł	Ł	Ń	Ň	Đ	Ů	Ř	"8x
'22x	Ř	Ś	Š	Ş	Ť	Ţ	Ů	Ű	
'23x	Ÿ	Ž	Ž	Ž	IJ	İ	đ	§	"9x
'24x	ă	ą	ć	č	ď	ě	ę	ğ	
'25x	í	ı	ı	ń	ň	ŋ	ó	ı	"Ax
'26x	ř	ś	š	ş	ť	ţ	ů	ű	
'27x	ÿ	ž	ž	ž	ij	i	ı	£	"Bx
'30x	À	Á	Â	Ã	Ä	Å	Æ	Ç	
'31x	È	É	Ê	Ë	Ì	Í	Î	Ï	"Cx
'32x	Ð	Ñ	Ò	Ó	Ô	Õ	Ö	Œ	
'33x	Ø	Ù	Ú	Û	Ü	Ý	Þ	ß	"Dx
'34x	à	á	â	ã	ä	å	æ	ç	
'35x	è	é	ê	ë	ì	í	î	ï	"Ex
'36x	ð	ñ	ò	ó	ô	õ	ö	œ	
'37x	ø	ù	ú	û	ü	ý	þ	ß	"Fx
	"8	"9	"A	"B	"C	"D	"E	"F	

Characters marked in *blue* need to be present (in the same positions) in every text encoding, because they are transparently passed through T_EX.

Table 9.22: Glyph chart for a T1-encoded font (ec-lmr10)

```
\DeclareTextCompositeCommand
  {LICR-object}{encoding}{simple-LICR-object}{code}
```

Although not used for the T1 encoding, there also exists a more general variant of `\DeclareTextComposite` that allows arbitrary code in place of a slot position. This is, for example, used in the OT1 encoding to lower the ring accent over the “A” compared to the way it would be typeset with T_EX’s `\accent` primitive. The accents over the “i” are also implemented using this form of declaration:

```
\DeclareTextCompositeCommand{\`}{OT1}{i}{\@tabacckludge`i}
\DeclareTextCompositeCommand{\^}{OT1}{i}{\^i}
```

What have we not covered for the T1 encoding? A number of diacritical marks are not placed on top of other characters but are placed somewhere below them. There is no special declaration form for such marks, as the actual placement usually involves low-level T_EX code. Instead, the generic `\DeclareTextCommand` declaration can be used for this purpose.

```
\DeclareTextCommand{LICR-object}{encoding}[num][default]{code}
```

For example, the “underbar” accent `\b` in the T1 encoding is defined with the following wonderful piece of prose:

```
\DeclareTextCommand{\b}{T1}[1]
  {\hmode\bgroup\o@lign{\relax#1\crrc\hidewidth\sh@ft{29}%
  \vbox to.2ex{\hbox{\char9}\vss}\hidewidth}\egroup}
```

Without going into detail about what the code precisely means, we can see that the `\DeclareTextCommand` is similar in structure to `\newcommand`. That is, it has an optional *num* argument denoting the number of arguments (one here), a second optional *default* argument (not present here), and a final mandatory argument containing the code in which it is possible to refer to the argument(s) using `#1`, `#2`, and so on. T1 has four such declarations, for `\b`, `\c`, `\d`, and `\k`.

`\DeclareTextCommand` can also be used to build font-encoding-specific commands consisting of a single control sequence. In this case it is used without an optional argument, thus defining a command with zero arguments. For example, in T1 there is no glyph for a % sign, but there exists a strange little “o” in position ‘30, which, if placed directly behind a %, gives the appropriate glyph. Thus, we can write

```
\DeclareTextCommand{\textperthousand}{T1}{\%\char 24 }
\DeclareTextCommand{\textpertenthousand}{T1}{\%\char 24\char 24 }
```

This discussion has now covered all commands that are needed to declare the font-encoding-specific commands for a new encoding. As mentioned earlier, only these commands should appear in encoding definition files.

Output encoding defaults

What happens if an encoding-specific command is used for which there is no declaration in the current font encoding? In that case, one of two things might happen: either L^AT_EX has a default definition for the LICR object, in which case this default is used, or the user gets an error message stating that the requested LICR object is unavailable in the current encoding. There are several ways to set up defaults for LICR objects.

```
\DeclareTextCommandDefault{LICR-object}[num][default]{code}
```

The `\DeclareTextCommandDefault` command provides the default definition for an *LICR-object* that is to be used whenever there is no specific setting for the object in the current encoding. Such default definitions can, for example, fake a certain character. For instance, `\textregistered` has a default definition in which the character is built from two others, like this:

```
\DeclareTextCommandDefault{\textregistered}{\textcircled{\scshape r}}
```

Technically, the default definitions are stored as an encoding with the name “?”. While you should not rely on this fact, because the implementation might change in the future, it means that you cannot declare an encoding with this name.

```
\DeclareTextSymbolDefault{LICR-object}{encoding}
```

In most cases, a default definition does not require coding but simply directs L^AT_EX to pick up the character from some encoding in which it is known to exist. The L^AT_EX kernel, for example, contains a large number of default declarations that all point to the TS1 encoding. Consider the following declaration:

```
\DeclareTextSymbolDefault{\texteuro}{TS1}
```

The `\DeclareTextSymbolDefault` command can, in fact, be used to define the default for any LICR object without arguments, not just those that have been declared with the `\DeclareTextSymbol` command in other encodings.

```
\DeclareTextAccentDefault{LICR-accent}{encoding}
```

A similar declaration exists for LICR objects that take one argument, such as accents (which gave this declaration its name). This form is again usable for any LICR object with one argument. The L^AT_EX kernel, for example, contains quite a number of declarations of the type:

```
\DeclareTextAccentDefault{"}{OT1}
\DeclareTextAccentDefault{\t}{OML}
```

This means that if the `\` is not defined in the current encoding, then use the one

from an OT1-encoded font. Likewise, if you need a tie accent, pick up one from OML¹ if nothing better is available.

```
\ProvideTextCommandDefault{LICR-object}[num][default]{code}
```

With the `\ProvideTextCommandDefault` declaration a different kind of default can be “provided”. As the name suggests, it does the same job as the declaration `\DeclareTextCommandDefault`, except that the default is provided only if no default has been defined before. This is mainly used in input encoding files to provide some sort of trivial defaults for unusual LICR objects. For example:

```
\ProvideTextCommandDefault{\textonequarter}{\ensuremath{\frac{1}{4}}}  
\ProvideTextCommandDefault{\textcent}{\TextSymbolUnavailable\textcent}
```

The first declaration provides an approximate glyph; in the second, the command `\TextSymbolUnavailable` generates an error message that the symbol is unavailable in the current encoding. Packages can then replace such definitions with declarations pointing to real glyphs.

Using `\Provide..` instead of `\Declare..` ensures that a better default is not accidentally overwritten if the input encoding file is read.

```
\UndeclareTextCommand{LICR-object}{encoding}
```

In some cases an existing declaration needs to be removed to ensure that a default declaration is used instead. This task can be carried out by the command `\UndeclareTextCommand`. For example, the `textcomp` package used to remove the definitions of `\textdollar` and `\textsterling` from the OT1 encoding because not every OT1-encoded font actually has these symbols.²

```
\UndeclareTextCommand{\textsterling}{OT1}  
\UndeclareTextCommand{\textdollar}{OT1}
```

Without this removal, the new default declarations to pick up the symbols from TS1 would not be used for fonts encoded with OT1.

```
\UseTextSymbol{encoding}{LICR-object}  
\UseTextAccent{encoding}{LICR-object}{simple-LICR-object}
```

The action hidden behind the declarations `\DeclareTextSymbolDefault` and `\DeclareTextAccentDefault` is also available for direct use. Assume, for example, that the current encoding is U. In that case,

```
\UseTextSymbol{OT1}{\ss}  
\UseTextAccent{OT1}{\'}{a}
```

¹OML is a math font encoding, but it contains this text accent mark.

²This is one of the deficiencies of the old TeX encodings; besides missing accented glyphs, they are not even identical from one font to another.

has the same effect as entering the code below. Note in particular that the “a” is typeset in encoding U — only the accent is taken from the other encoding.

```
\fontencoding{OT1}\selectfont\ss}
\fontencoding{OT1}\selectfont'\fontencoding{U}\selectfont a}}
```

Declarations for the `tuenc.def` file

Unicode engines

For the Unicode encoding TU used in Unicode engines there are additional declarations available. The encoding is implicit, because it is normally TU. For special applications it can be altered by changing `\UnicodeEncodingName`.

```
\DeclareUnicodeAccent{LICR-accent}{slot}
```

This is similar to `\DeclareTextAccent`, but instead of using the `\accent` command of T_EX to position the accent on top of a following base character, it places the accent after it. This is the correct approach if the accent is a Unicode “combining character”. It is then the task of the font to combine both in the correct way.

```
\DeclareUnicodeComposite{LICR-accent}{base-character}{slot}
```

This is a wrapper around `\DeclareTextCompositeCommand`. It first tests if the declared composite exists as a single glyph in the current font (which may or may not be the case) and if so uses the composite *slot*. Otherwise, it falls back to the default definition for the *LICR-accent* in TU.

```
\DeclareUnicodeSymbol{LICR-cmd}{slot}
```

This is a simple wrapper around `\DeclareTextSymbol` with the encoding made implicit but otherwise no extra processing.

```
\DeclareUnicodeCommand{LICR-cmd}{definition}
```

This is another wrapper; this time for `\DeclareTextCommand` with the encoding made implicit, i.e., syntactic sugar.

A listing of standard LICR objects

Table 9.23 provides a comprehensive overview of the L^AT_EX internal representations available with the three major encodings for Latin-based languages: OT1 (the original T_EX text font encoding), T1 (the L^AT_EX standard encoding, also known as Cork encoding), and LY1 (an alternate 8-bit encoding proposed by Y&Y). In addition, it shows all LICR objects declared by TS1 (the L^AT_EX standard text symbol encoding) historically provided by loading the `textcomp` package but nowadays available by default.

The first column of the table shows the LICR object names alphabetically sorted, indicating which LICR objects act like accents. The second column shows a glyph representation of the object.

The third column describes whether the object has a default declaration. If an encoding is listed, it means that by default the glyph is being fetched from a suitable font in that encoding; `constr.` means that the default is produced from low-level TeX code; if the column is empty, it means that no default is defined for this LICR object. In the last case a “Symbol unavailable” error is returned when you use it in an encoding for which it has no explicit definition. If the object is an alias for some other LICR object, we list the alternative name in this column.

Columns four through seven show whether an object is available in the given encoding. Here **X** means that the object is natively available (as a glyph) in fonts with that encoding, **O** means that it is available through the default for all encodings, and `constr.` means that it is generated from several glyphs, accent marks, or other elements. If the default is fetched from TS1, the LICR object is also always available but depending on the current font family, it might have a suboptimal representation; see Section 9.5.6 on page 694 for details.

Unicode engines

All font-encoding-specific commands are available in the TU encoding.

Table 9.23: Standard LICR objects

LICR Object	Glyph	Default from	OT1	T1	LY1	TS1
ABC..XYZ (Uppercase letters)	ABC..XYZ		X	X	X	
abc..xyz (Lowercase letters)	abc..xyz		X	X	X	
0123..9 (Digits)	0123..9		X	X	X	X

This picture of Sebastian was taken 2007 in Cinque Terre.

I dedicate this edition to all my friends in the $\text{T}_{\text{E}}\text{X}$ world and in particular to the memory of my good friend Sebastian Rahtz (1955–2016), with whom I spent many happy hours discussing parenting, literature, \LaTeX , and other important aspects of life [146].

Foreword, Part II

I'm back! Readers who have already read the first part of this comprehensive third edition of *The L^AT_EX Companion* may recall that I wrote the Foreword to that book. Those who have not seen that piece might want to start there to find my perspective on this unique resource, which I was proud to publish in its first two editions. You will also see there my praise for its authors: An incredible amount of work goes into these Companions, sorting and compiling for every L^AT_EX user what is most useful to know, and what should be avoided, defining thereby the current state of the system. If you are serious about learning and using L^AT_EX to format your writing, you could not be better advised than to keep both these new volumes close at hand.

One passing reference I made in my first Foreword, given the reaction to it in some quarters, bears immediate attention: digital rectal examinations. If you missed that reference, you probably are wondering how it could possibly relate to L^AT_EX typesetting. Some of the people asked to review the Foreword were apparently equally puzzled. In context, I think that the example made a good point, but the reviewers, for whatever reason, seemed unable to get the procedure out of their mind. As a result, they missed my broader observation about the use of L^AT_EX in surprisingly diverse fields, and in unusual places. If only those reviewers could have seen the initial draft, in which I described in greater detail — well, never mind; that is all behind us now!

I actually have very little more to say in this second Foreword beyond what I said in the first, except to emphasize that, especially if you are new, or relatively new, to L^AT_EX, you probably should begin with the first of the two volumes that comprise this revision. Honestly, I think that the only reason Frank asked, or allowed, me to write it was to maintain a certain symmetry, each book thus having an apparent beginning and end, even if, logically, they're really one book in the guise of two. Given the growth in L^AT_EX use, and the ongoing development of contributions to the system

itself, I see future authors, likewise intent on being definitive, projecting a yet-unknown number of volumes.

With little otherwise to relate, you might at least be interested to know that I offered Frank cover ideas for the new books — too late, he informed me, and I think I heard a sigh of relief. One idea suggested a parody of Leda and the Swan. It pictured a bespectacled swan hunched over a computer trying to resolve some onetime typesetting issue, while an obviously bored, half-naked Leda lay nearby on a luxurious bed, hoping eventually to give birth to \LaTeX (not sure how to fit Leslie into that story). I know, given the swan's divinity, why the need for help with typesetting — or any interest in writing, for that matter? I guess I recalled the large graffiti I saw years ago on a Metro station wall in Paris: “God is studying French, and having trouble with the subjunctive.”

Anyway, I suspect Frank was concerned that potential users might think that \LaTeX is hard to learn and use — which it is not. Rather, it is just so rich with tools and techniques, and so many are available, you simply need help in knowing which are the most valuable — the very purpose of this revision. Just flip through the pages to see what I am talking about! Perhaps Frank was also concerned that people would imagine that the swan had become a new \LaTeX mascot. There have already been, what, lions, ducks, frogs — and do you remember the first Companion, known as the doggie book (proof that my cover ideas work)? Now we see there is a hummingbird.

So I proposed a second cover, a scene that might suggest the origins and nature of *The \LaTeX Companion* as an indispensable aid to a successful and more pleasurable typesetting experience. Picture, then, another snowy Alpine scene (as first illustrated in the aforementioned doggie book), this time with an old lion and lioness, seen from the back, relaxing in adjacent bathtubs. A hummingbird is seen perched on a rescue keg lying in the snow, under the banner, “ \LaTeX IS HERE”, or, like *Seinfeld* characters seeking serenity, “ \LaTeX NOW!”. Receding pawprints add a nostalgic touch. As with the swan cover, of course, given the timing, I had to ask Frank to consider this second idea for the next edition — and this time, I am sure I heard a scream.

I had better end there and let you get into the content that truly makes the third edition a necessary addition to every \LaTeX user's library. There is only so much that a mythical swan, revitalized lions, and, yes, digital rectal examinations can do for you — well, the swan and the lions, in any case.

Peter S. Gordon
Publishing Partner (Ret.)

Author note from Frank: I cannot believe I approved these Forewords! ☺

Preface, Part II

Divide each difficulty into as many parts
as is feasible and necessary to resolve it.

René Descartes (1595–1650)

Taking Descartes’s advice to heart, we decided to split this edition of *The L^AT_EX Companion* into two parts of roughly a thousand pages each. Thus, we are now at the midpoint in describing the fascinating features of today’s L^AT_EX and we start with a chapter on text and symbol fonts, which is completely new — ten years ago nearly none of these fonts could have been used with L^AT_EX at all. The same is true for Chapter 12 on math font setups, the discussions of `mathtools`, `biblatex`, `upmendex`, new developments in `babel`, the new features of the L^AT_EX format covered in Appendix A, and various other new packages discussed in the upcoming chapters.

Otherwise, given that this is really just the second part of “one book in the guise of two”, as Peter put it in his Foreword, there is nothing new to reveal if you have read the Preface to the first part.

Thus, instead of repeating anything from there, all we are going to do is to repeat the section on conventions used in this book, because that is probably helpful to have close at hand if you have the second part open on your desk.

Frank Mittelbach

CHAPTER 10

Text and Symbol Fonts

10.1 Overview	2
10.2 Samples of larger font families	11
10.3 Humanist (Oldstyle) serif fonts	36
10.4 Garalde (Oldstyle) serif fonts.	38
10.5 Transitional/Neoclassical serif fonts.	46
10.6 Didone (Modern) serif fonts	60
10.7 Slab serif (Egyptian) fonts.	64
10.8 Sans serif fonts.	67
10.9 Monospaced (typewriter) fonts	88
10.10 Historical and other fonts	97
10.11 Fonts supporting Latin and polytonic Greek.	106
10.12 Fonts supporting Latin and Cyrillic.	110
10.13 The \LaTeX world of symbols	113

When we wrote the first edition of the *\LaTeX Companion* in 1994, the section on available text fonts for \LaTeX was a few pages long and listed a handful of font families. Not because they were best in class, but because that was all that was available including those of a somewhat dubious quality. Basically when typesetting with \TeX in those days, one could use any font as long as it was called Computer Modern.

A decade later the situation finally started to change, and it was in theory possible to use any font available in Type 1 format [1] — but only after somewhat extensive work preparing the necessary support files needed by \TeX , in particular the font metric files (`.tfm`) and usually virtual font files (`.vf`) that reencoded the fonts to put the glyphs into the positions expected by the \TeX engine. Providing these was not magic, especially after the appearance of the `fontinst` program¹ by Alan Jeffrey, Rowland

¹This is actually a \TeX file that, when processed and given the right configuration data, produced the necessary helper files in human-readable format. In a further step those had to be converted by external programs to the binary format used by \TeX .

McDonnell, and Lars Hellström, but it took time and effort (even if necessary only once per font) and a good understanding of the underlying mechanisms. Thus, the number of available text fonts for use with \TeX compared to other programs remained severely restricted. The second edition of the book again covered all that was freely available for \TeX users, which amounted to fewer than two dozen font families. Of course, the CTAN archive already then contained some further support packages for a few commercial fonts. They were not included because the packages were useless unless you owned the particular family.

But with the third edition I faced a problem. With Unicode engines you can use essentially any freely or commercially available font by simply specifying it in the `fontspec` setup of your document. But also for the `pdf \TeX` engine, font support exploded due to two factors: first the number of freely available fonts on the Web in either Type 1 [1], TrueType [8], or OpenType [127] format grew enormously, and second a few individuals like Marc Penninga, the author of `autoinst`, and Bob Tennent, Michael Sharpe, and a few others¹ took the time to prepare configuration files for Marc's `autoinst` program and with the necessary further adjustments and documentation produced packages that made a huge number of those freely usable fonts available to the \TeX community at large.

My initial thought was to select only a few of the high-quality free fonts and largely ignore the rest — with just a mention that you find more possibilities in your \TeX installation and on CTAN. But while working through all the font packages on CTAN to make a selection, I realized how difficult it is to hunt for them and that most likely any family not described in an overview remains unnoticed by the majority of users. Furthermore, while in the early days most free fonts were of a somewhat dubious quality, that too has now changed quite impressively for the better.

So in the end I decided to continue the tradition of offering a fairly comprehensive overview² about today's freely available fonts for \TeX so that you can make an informed selection by just skimming this chapter and comparing the different possibilities and only then look further at the package documentation of the fonts you have chosen. You may also want to take a look at the online font catalogue maintained by Palle Jørgensen [77].

10.1 Overview

*General font
availability*

All fonts described in this chapter are freely available and with a few exceptions are included in the major \TeX distributions such as \TeX Live or `MiK \TeX` so that you can start using them directly. We made two exceptions and also included the commercially available Cambria fonts as well as the Lucida font families that we use in this book. The Cambria fonts, while under a proprietary license, ship as part of Windows and

¹All package authors are acknowledged next to their work and listed in the index. There are too many to enumerate here. However, Bob and Michael are the ones who produced the major part of the work, which I think deserves an explicit acknowledgment.

²For the first time restricted to only high-quality or otherwise (for some reason) interesting fonts. A heartfelt thanks to Adam Twardoch who helped me a lot with his knowledge and expertise to select the high-quality fonts from the huge number of freely available fonts today.

Office products and are therefore widely available without the need for buying an additional license. They offer excellent math support and for that alone are worth a closer look. The Lucida families are sold by the T_EX Users Group (TUG) at a special price for members of TUG and several other user groups.¹

In the open source world, “free” is a widely debated word, and some fonts are just not “free enough” to be included in free software distributions, because their license is somewhat restrictive, typically either forbidding modifications of the fonts (which is most likely not any issue for the readers of this book) or disallowing commercial usage. The latter refers to actions such as selling them or distributing them as part of a commercial system — none of the licenses of the fonts we cover prohibit the free use of the fonts even if the result, say, a book like this, is then sold. Thus, this should not pose a problem either, but of course, you should be aware that fonts you need to install “manually” have a special license, and you better check what it says if you intend to do anything with it other than simply typesetting your texts.

Omitting high-quality fonts because of license restrictions (even if very minor) is a sensible approach, as it means that the users of the distribution can rely on the fact that everything contained is covered by one of the major free licenses and that there are no restrictions on use and only well-known ones on modification; e.g., most L^AT_EX software uses the L^AT_EX Project Public License (LPPL), GNU Public License (GPL), or any other of the few major open source licenses.

But of course, it puts an additional burden on the user, as they have to manually install the fonts (besides checking the license requirements). Fortunately, there is an easy way to integrate such font packages into your installation. At the T_EX Users Group website a script by Reinhard Kotucha is provided. It is a simple matter of downloading the `install-getnonfreefonts` installer from <https://www.tug.org/fonts/getnonfreefonts/> and processing it on the command line (in a Windows, macOS, or Linux terminal window) using

```
texlua install-getnonfreefonts
```

As this is a Lua program and `texlua` is part of the standard distributions, this works on any operating system, provided your user has write access to the distribution directories. After this you have the program `getnonfreefonts` available on your system, and you can invoke it with lines such as

```
getnonfreefonts --sys --help      # see the help info or  
getnonfreefonts --sys --lsfonts  # list all available fonts or  
getnonfreefonts --sys luximono   # (re)install a fonts package or  
getnonfreefonts --sys --all      # (re)install all available fonts
```

The line first displays the program usage information and the available options; the second gives you an overview about the currently supported fonts and their

¹The set includes matching serif, sans serif, and typewriter families; a full set of fonts for use in math; and several specialized fonts; see Table 10.11 on page 22 for an overview. They can be used with all T_EX engines if both Type 1 and OpenType versions are ordered, which you can do at <https://tug.org/store/lucida/order.html>.

state on your installation; the third installs or reinstalls such a font (or more if you add additional font names); and the final one installs or updates all supported font packages (which are eleven in total at the moment). Instead of `--sys`, you can use `--user`, in which case the installation is done in the user's T_EX tree instead of the system-wide one. However, except in a few special cases, this is *the wrong thing to do*, so please read <https://tug.org/texlive/scripts-sys-user.html> first if you are considering using `--user`, because of its possibly undesirable side effects.

10.1.1 Notes on the font samples

All font families in this chapter are exhibited using the same example text to allow for easy comparison and at the same time to show many details and possible limitations of the fonts. The standard setup uses the following text:

Palatino 10pt/12.4pt
(qp1) *TeX Gyre Pagella* With a price of £148, **almost anything** can be found **FLOATING IN**
FIELDS. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve*
vis-à-vis the dæmonic *phoenix's official rôle* in fluffy soufflés?

In the margin we show the common name of the font (*Palatino*), the font size and the leading used (*10/12.4pt*), the NFSS family name to refer to it in parentheses (qp1), and finally with gray background the OpenType or TrueType name to use with Unicode engines (*TeX Gyre Pagella*). Depending on the length of the font names, this may be split differently over up to four lines.

The text is not typeset justified but slightly ragged right (still allowing hyphenation as one can see in a few of the later samples; e.g., on page 34). This is done so that the word spaces are not (or only minimally) altered from their default width. Most examples are set in 10/12pt, which is the default in most document classes, but sometimes we use a larger leading and/or a smaller or larger font size to account for the look and feel of the family.

The example text attempts to show different aspects of the font while still being concise (otherwise this chapter would be even longer). It contains some **bold** text, some **BOLD AND NONBOLD SMALL CAPITALS**, a *slanted word*, and a *few words in italics*. Above, these words are all typeset in blue. In the real samples they would be in black, unless the corresponding shape or series either is not available or is faked.

For instance, most families do not have both an italic and an oblique/slanted shape. Sometimes it is missing, but quite often the oblique shape is really just an alias for italics (or vice versa), which is fairly easy to see if you look at the shape of the “a” in “*naïve*” and “*official*” and compare it to “can” in the first line. Regardless of whether the slanted or italic shape is missing or aliased, it is shown in blue.

The bold text is normally shown in blue only if the series is missing altogether; the exception is the Concrete family where it is faked (by aliasing it to the bold typeface of a different font family, which is a somewhat questionable approach).

When the SMALL CAPS TEXT is shown in blue, half of the time it is because there is simply no such shape in the family and in the other half because the small capitals are faked using a scaled-down version of the uppercase letters. As explained on

Family	Series	Shapes	Typeface Examples
<i>⟨official font family name⟩</i>		<i>⟨font name (or names)⟩</i>	<i>(Encodings: ⟨list of supported font encodings⟩)</i>
<i>⟨NFSS family⟩</i>	<i>⟨series value(s)⟩</i>	<i>⟨shape value(s)⟩</i>	Font sample <i>with several</i> DIFFERENT SHAPES, weights , and/or widths (<i>but not all possibilities</i>)
<i>⟨related official font family name⟩</i>		<i>⟨font name (or names)⟩</i>	<i>(Encodings: ⟨list of supported font encodings⟩)</i>
<i>⟨NFSS family⟩</i>	<i>⟨series value(s)⟩</i>	<i>⟨shape value(s)⟩</i>	Font sample <i>with several</i> DIFFERENT SHAPES, weights , and/or widths

Supported figure styles for ⟨font family⟩ are ⟨list of figure styles⟩.

Bold extended weights (bx) exist as an alias for bold medium (b) if not explicitly listed.

*The **font names** with gray background are for use with the fontspec package in Unicode engines.*

Table 10.1: Structure of the font family classification tables

page —I 654 this approach gives inferior results — sometimes still acceptable, but usually not really. In other words, such fonts do not allow for using `\textsc` or only in an emergency.

But not only are different shapes shown in the example, the text also contains a number of diacritics, several special characters, and also most of the common f-ligatures such as ffi, fl, and ffl so you can see how they are typeset.

Finally, you should pay special attention to the number 148 in the first line. Whenever supported by the family, these digits are typeset as oldstyle numerals, and many fonts support this style (Palatino/Pagella above, for example, does not). Thus, if they are typeset as lining numbers, then the font does not support alternative number styles. If they are shown as oldstyle numbers, then this is usually adjustable through options to the support package or by changing the suffix of the family name if you use NFSS commands directly; see the next section.

10.1.2 Notes on the font family tables

In addition to the sample text, we show for each font family a table that contains the necessary information to select a font from that family in a document using the NFSS conventions. These tables are always identically structured; a sample table is shown as Table 10.1.

We show the *⟨official font family name⟩* followed by the *⟨font name or names⟩* that you need to use when accessing the family in a Unicode engine using fontspec. In the remainder of the line we then list the supported encodings, e.g., OT1, T1, etc. The next lines show the NFSS classification, i.e., the NFSS *⟨family⟩* and supported *⟨series⟩* and *⟨shape⟩* values, followed by a short text sample exhibiting some of the series/shape combinations (but usually not all).

If the font family consists of several distinctive designs, e.g., a serif, a sans serif, or a monospaced design, then this structure is repeated for the related font families as often as necessary.

We do not list (bx)
in tables

Series or shape values that are given in parentheses are faked in one way or the other. For example, (it) means the family has no real italics shape, and the oblique shape is used as a substitute, or vice versa if you see (sl). What we do not show in any table is (bx). The extended bold series is nearly always implemented as an alias to the medium bold series, but showing that in all tables takes up a lot of unnecessary space. In other words, in all tables you should mentally add (bx) next to every b series, unless the series list contains bx already, which means there is a real difference between bold medium (b) and bold extended (bx).

At the bottom of the table there may be some table notes. If the family supports several figure styles (e.g., oldstyle numbers or table numbers), we list them here. Any other pertinent information for this family is given there as well.

NFSS font family
naming conventions

If the *NFSS family* name consists of a few apparently random letters (like qpl for Pagella), it is a clear indication that the \LaTeX support files for this family got created a long time ago when packing a lot of information into a few bytes was essential and file names needed to conform to the 8+3 rule for DOS and Windows systems; see [16] for the description of that scheme.

However, these days the majority of *NFSS family* names are quite uniformly constructed from the *official font family name*¹ (typically in mixed case with spaces dropped), e.g., FiraSans or NotoSansMono followed by a suffix starting with a hyphen that indicates the figure style. This is nice because it is easy to remember, provides direct feedback, and allows one to quickly change a font from lining figures to oldstyle tabular figures, etc., when using NFSS commands directly.

- LF This font uses lining figures, i.e., ones that all have the same height similar to capitals in the font. The glyph width may vary.
- TLF This font has lining figures of identical width. This makes them suitable for tabulating numbers (which explains the name “table figures”).
- OsF This font has oldstyle figures of different heights and depths and possibly different widths.
- TOsF This font has oldstyle figures with identical widths suitable for tables.

There are two further suffixes for fonts not intended for direct typesetting but as support for implementing the commands `\textin` and `\textsu` discussed below:

- Sup This font contains superior digits, punctuations, and letters, often only an incomplete set, e.g., *abdeilmnorst* to support 1st, 2nd, etc. With the help of this special figure style, the command `\textsu` is implemented.
- Inf This font contains inferior glyphs, usually only digits and some punctuations. With the help of this special figure style, the command `\textin` is implemented.

¹Unfortunately, that is not always the case. Some of the freely available OpenType fonts have license restrictions that already require a name change when only the font format is changed to Type 1 (as needed by pdf \TeX). You therefore sometimes find crippled names in the tables of this chapter; e.g., instead of Merriweather, we get *Merriwthr-OsF* as the NFSS family name — a pity, but it cannot be helped.

The *NFSS family* name in the table normally shows the `-LF` or `-TLF` suffix. If the family supports other figure styles, then they are mentioned in a table note.

Unicode engines

Most font tables list TU as one of the supported encodings. This means that the font family can be (easily) used with Unicode engines, such as X_YTeX or LuaTeX. If this encoding is missing, one should normally use that family only with pdfTeX.

Many tables also list the LY1 encoding, which is an alternative to L^AT_EX's standard T1 encoding. It omits a few uncommon glyphs available with T1, which has the advantage that it therefore contains a few free slots. In some families these slots are then filled with additional ligatures available in the OpenType version of the font that would otherwise be inaccessible if the font is used with pdfTeX.

*Extra ligatures when
using LY1 encoding*

10.1.3 Font support packages

As mentioned earlier, the bulk of the font support packages has been provided by a few individuals, and because of this, the majority of the packages are very similar in nature and provide identically named options for the same tasks in most circumstances. Thus, instead of adding a list of every option or command to the description of each of the more than 120 font packages, we give an overview here so that you know what to expect. For further details you then have to consult the package documentation, but in most cases this overview will hopefully suffice.

Please also note that many of the packages, in particular those by Bob Tennent, provide compatibility between the different processing engines; i.e., they successfully hide the differences between NFSS as used by pdfTeX and fontspec needed in the Unicode engines X_YTeX or LuaTeX.

Package naming conventions

Not so consistent are, unfortunately, the package names. While they usually have a clear relationship to the font family they support, you will find all sort of variants, from all lowercase with or without hyphens to mixed-case package names. Often this is due to the age of a package and to changes in how file names for support files got generated by fontinst or autoinst, and it is nothing that can easily be altered after the fact.

Figure style options

If font families support different figure style variants, then these are selectable in nearly all packages through the following set of options (each of which has a short name and a long name):

<code>lining</code> (<code>lf</code> or <code>nf</code>)	or	<code>oldstyle</code> (<code>osf</code>)	Select lining or oldstyle figures.
<code>proportional</code> (<code>pf</code>)	or	<code>tabular</code> (<code>tf</code>)	Select proportional or table figures.

They can (and may have to) be combined, e.g., `oldstyle,tabular` would internally request the font family with the `-TOSF` suffix in its name.

*Support for different
figure styles within
the document*

Packages for fonts that support more than one such figure style usually also implement commands to access different styles of numerals within the document. The commands are `\textfigures` (oldstyle), `\liningfigures`, `\tabularfigures` (identical width), and `\proportionalfigures`. They all expect one argument in which you can place the number to typeset. For example, if you have selected a family with the `-OsF` suffix (oldstyle numerals), then `\liningfigures` would switch temporarily to the font with the `-LF` suffix (if that exists as well).

Font scaling, weight, and width selection

Many packages also allow you to scale the fonts up or down by providing a scaling factor so that you can ensure that they become visually compatible with other fonts used. In most cases the option `scaled` or `scale` can be used, but sometimes only `scale` is provided.

The more modern packages often provide options to select the weight to be used as the default. Which option names are available then depends on what weights are offered by the family, but the names as such are usually a subset of the following list: `thin`, `ultralight`, `extralight`, `light`, `regular`, `medium`, `semibold`, `bold`, `ultrabold`, `heavy`, `black`, or `extrabold`. These option names reflect what has been used by the font designer as the weight name, so if the extra-bold weight is called `heavy`, then that is used as an option name. Sometimes packages also support short forms like `sb` for `semibold`, etc. For details you have to consult the individual package documentation.

Some families offer condensed versions, and in that case the support packages normally support the option `condensed` to select that variant as the default.

Changes to `\rmdefault`, `\sfdefault`, and friends

Packages supporting a single font family normally ensure that the family is automatically used. This is done by changing `\rmdefault` when it is a serif font, `\sfdefault` when it is a sans serif font, and `\ttdefault` if it is a monospaced design.

This means that a serif font automatically becomes the document default font, as that is determined by `\familydefault`, which, if unchanged, simply calls `\rmdefault`. However, some serif fonts are normally not intended to be used for a whole document. For example, Cinzel is suitable only for displays, because it contains only uppercase letters. Its support package therefore provides only commands such as `\textcinzel` for selecting the font but leaves `\rmdefault` untouched unless you give it the option `default`. For some reason this option is also needed with the `gfsbodoni` package even though the font is a perfectly reasonable document font and could have been set up automatically.

Since you may want to set up a sans serif font as the default font for your document, packages that load such families usually support the option `sfdefault`. If given, this option changes `\familydefault` to point to the sans serif family. A few packages call this option `default` instead.

So while there is some overall consistency, there are also a few packages that use the option names differently. Exceptions are explicitly listed with the packages.

Multifamily support

If a package sets up several font families in parallel, e.g., a sans serif and a monospaced family, then this can be very convenient, but it is not always appropriate. To support a selective setup, such packages usually offer the options `rm`, `sf`, or `tt` as appropriate so that one can request that only the roman (serif) and/or the sans serif and/or the typewriter family is set up instead.

Such packages may also prefix other option names with `rm`, `sf`, or `tt` to denote that they should apply only to that particular family setup. For example, `sfsf` would state that the sans serif family should get oldstyle numbers, but this convention is not implemented very often.

Some packages have their own naming scheme for such options, so if the above names do not work with one of the packages discussed in Section 10.2, consult their documentation to see what they provide instead.

Commands defined by font packages

Some of the older font support packages provide only fairly limited features, e.g., changing `\rmdefault` or `\sfdefault` and maybe offering a `scaled` option. However, with more recently developed packages you usually also get a number of document commands defined. We give a short overview of what might be available; the details vary from package to package, and you have to read the relevant package documentation for this.

Many packages add commands to access the font family that they support, in addition to, or as an alternative to, making it available via `\textrm` or `\textsf`, etc. In most cases the command names use the following convention: `\text{<pkg-name>}` with one argument and `\<pkg-name>` for the declaration form that switches to the font. For example, the `cinzel` package offers `\textcinzel` and `\cinzel`.

Support for additional \text.. commands

Roughly fifty packages support superior figures and about twenty also support inferior figure styles. This is shown in the font tables by listing `-Sup` or `-Inf` as supported figure styles. If so, the commands to access these glyphs are normally `\textsu` and `\textin` or as declarations `\sufigures` and `\infigures`. If available, these command usually produce much better results than L^AT_EX's generic `\textsuperscript` and `\textsubscript` commands, as those commands simply take the current font, use it in a smaller size, and raise or lower the result. For comparison here is text in *Alegreya* (see page 11) showing both methods:

Support for superior and inferior glyphs

10-1-1

	<code>\usepackage{Alegreya}</code>	
Catch ₂₂ in Room ¹³	<code>Catch\textin{22}</code>	<code>in Room\textsu{13}</code> <code>\par</code>
Catch ₂₂ in Room ¹³	<code>Catch\textsubscript{22}</code>	<code>in Room13</code>

The problem with both commands or the declarations is that they normally unconditionally switch to the package font, so if you load two packages that both define them, the last one loaded wins.

There are sometimes a number of other commands or options available with individual packages, but there is little consistency across the whole set. So once you

have selected a particular set of font families for your document, it might be worth reading the documentation to see if there is anything else not covered here.

10.1.4 Direct use of the fonts (without a package)

Using a font support package is often convenient, but it is seldom really necessary, and in some cases it is actually counterproductive. For example, most font packages install the family as a default of some sort, e.g., as the document sans serif family (`\sfdefault`). But if you want to use that font for only a special effect, then you have to undo that kind of setup or make sure to load all support packages in the right order so that part of their configuration gets undone by the next package (if possible).

Fortunately, the font classification tables are enough to directly use any font exhibited in this chapter. All you have to do is to place the relevant data from the tables into the appropriate NFSS commands, e.g., `\fontfamily`, `\fontseries`, `\fontshape`, or `\usefont`, or use them for changing the document defaults, e.g., `\rmdefault`, `\sfdefault`, and so on.

In the next example we set up Fira Sans with lining figures (`-LF`) as the sans serif document font and then use Alegreya with oldstyle figures (`-OsF`) in ultra-bold at 42 points (without any leading) for a splashing headline (using `\usefont`). We then change the size to `\tiny` and the font to `\sffamily`. That means the text would still be in ultra-bold (which is available in Fira-Sans; see Table 10.5 on page 14), but we want a strong contrast, so we go for extra-light via `\fontseries{el}`. We can omit the `\selectfont` as that is implicitly done by `\sffamily`.

Alegreya- Ultra 42

A tiny light Fira Sans 42

```
\renewcommand\sfddefault{FiraSans-LF}
\centering
\fontsize{42pt}{42pt}%           Select a size
\usefont{T1}{Alegreya-0sF}{ub}{n}% Select a font
Alegreya-Ultra~42                %           Go

\tiny\sfontseries{el}\sffamily    %           Change
A tiny light Fira Sans 42
```

10-1-2

Unicode engines

When typesetting using one of the Unicode engines, the procedure is slightly different, because with `fontspec` only the medium and bold series are set up automatically. Therefore, something like ultra-bold or extra-light is not available out of the box and thus cannot be requested in the way we did in the previous example without first doing some setup work using the `FontFace` key or the `\newfontface` command of `fontspec`. For example:

```
\setsansfont{Fira Sans}[FontFace={el}{n}{FiraSans-ExtraLight.otf}]
\newfontface{AlegreyaHeading}{Alegreya-Black.otf}
```

How to find the correct font file names — starting with the data from the font classification tables in this chapter — is described at length in Section 9.6, starting on page 705.

Family	Series	Shapes	Typeface Examples
<i>Alegreya</i>	Alegreya (Encodings: T1, TS1, OT1, LGR, LY1, and TU)		
Alegreya-LF	m, sb, b, eb, ub	n, it, (sl), sc, scit, (scsl)	Alegreya <i>italic</i> , bold , and SMALL CAPS
<i>Alegreya Sans</i>	Alegreya Sans (Encodings: T1, TS1, OT1, LGR, LY1, and TU)		
AlegreyaSans-LF	el, l, m, sb, b, eb, ub	n, it, (sl), sc, scit, (scsl)	Alegreya Sans in ultra-bold and thin

Supported figure styles for *Alegreya* and *Alegreya Sans* are -LF, -OsF, -TLF, -T0sF, -Sup, and -Inf.

Table 10.2: Classification of the Alegreya font families

10.2 Samples of larger font families

We start by discussing the freely available bigger families in alphabetical order, i.e., those that offer matching serif, sans serif, and monospaced designs (or at least two of them). We already covered L^AT_EX’s standard families Computer Modern and Latin Modern in Section 9.5.1 on page 1684 in the previous chapter, so they are not repeated here. Samples for all of them (including CM and LM fonts) are later repeated in the sections devoted to serif, sans serif, and typewriter fonts, to allow for easy comparison to other fonts that have similar characteristics.

10.2.1 Alegreya

The Humanist typeface Alegreya, designed by Juan Pablo del Peral, is intended for body text but also works well in display sizes. One of its characteristic features is the widening of its stems towards the top. It is offered in five weights, upright, italics, and Small Caps, and has a matching sans serif Alegreya Sans.

L^AT_EX support for all engines is provided by the *Alegreya* and *AlegreyaSans* packages by Bob Tennent with the typical options such as `scaled`, `oldstyle`, etc.

With a price of £148, **almost anything** can be found FLOATING IN **FIELDS**.
 — ¿But aren’t Kafka’s Schloß & Æsop’s Œuvres often *naïve* vis-à-vis the
 dæmonic *phœnix’s official rôle* in fluffy soufflés?

Alegreya 10pt/12pt
 (Alegreya-OsF) **Alegreya**

Here is a sample of Alegreya Sans equally well equipped with weights and shapes. Just like its serified counterpart it offers all standard font faces in even more weights, including small capitals in each of them. It also has true italics, though there is no oblique/slanted font face — for this italics are substituted as elsewhere:

cmtl	m	n, sl	CM Bright Typewriter Light and <i>oblique</i>

Table 10.3: Classification of the Computer Modern Bright font families

10.2.2 CM Bright — A design based on Computer Modern Sans

The Computer Modern Bright (CM Bright) fonts by Walter Schmidt (1960–2021) are based on the METAFONT sources of Computer Modern Sans. This family of sans serif fonts is designed to serve as a legible body font. It comes in three weights with matching typewriter and math fonts, including the AMS symbols. L^AT_EX support for the pdfL^AT_EX engines is provided through the package `cmbright`. A sample page with mathematics is shown in Figure 12.42 on page 290.

Unicode engines

The fonts exist only as METAFONT sources and in Type 1 format (in T1 or OT1 encoding) and are therefore not really suitable for Unicode engines.

In the example below we show semi-bold (sb) instead of using the default bold extended series, as this is a good combination when typesetting in CM Bright.

CM Bright 10pt/12pt (cmbr)
— no OpenType —

Œuvres often naïve vis-à-vis the dæmonic *phoenix's official rôle* in fluffy soufflés?

10.2.3 DejaVu — A fork of Bitstream Vera

Bitstream Vera is a freely available set of typefaces in TrueType format designed by Jim Lyles from Bitstream. It consists of slab serif, sans serif, and monospace fonts in two weights. The monospaced font is suitable for technical work with a clear distinction of often similar characters. The sans serif font is the default font used by Python's Matplotlib library for producing plots.

The Vera families were released with a license that permits changes, and as a result several projects used Vera as a basis. The DejaVu project was initiated by

Family	Series	Shapes	Typeface Examples
<i>DejaVu Serif</i>	DejaVu Serif	(Encodings: T1, TS1, T2A, T2B, T2C, OT1, X2, LGR, and TU)

Table 10.4: Classification of the DejaVu (Vera) font families

Štěpán Roh with the aim to provide a wider range of characters while maintaining the original look and feel through the process of collaborative development.

For \LaTeX , there has been support for the original Vera fonts for a long time under the name Bera fonts, but this covered only the Latin character encoding T1. More recently Pavel Farář provided pdf \TeX support for the DejaVu families (which offers additional shapes and also covers Greek and Cyrillic) through the packages `DejaVuSerif`, `DejaVuSans`, `DejaVuSansCondensed`, and `DejaVuSansMono`. All packages support the option `scaled`, which is helpful if the fonts are combined with other families. There also exists the package `dejavu` that simply calls all three packages in turn.

Unicode engines

For Unicode engines you can instead use the package `dejavu-otf` by Herbert Voß, which provides the necessary `fontspec` support and also sets up the matching math fonts developed in Poland by \TeX Gyre. For available options refer to the package documentation. An example page with mathematics is shown in Figure 12.41 on page 289.

With a price of £148, **almost anything** can be found **Floating In Fields**. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phoenix's official rôle* in fluffy soufflés?

10.2.4 Fira fonts

The Fira fonts have been designed by Erik Spiekermann and Ralph du Carrois for the Firefox OS. The Humanist sans serif typeface Fira Sans is available in seventeen weights of which a suitable subset has been set up for use with L^AT_EX. The accompanying monospaced font Fira Mono is available in three weights, offers oblique (and faked italics), but does not offer Small Caps shapes.

L^AT_EX support for all engines is provided by the packages FiraSans and FiraMono by Bob Tennent with the typical options such as scaled, oldstyle, etc.

Fira Sans 10pt/12pt
(FiraSans-OsF) **Fira Sans**

(GandhiSans-OsF)
Gandhi Sans

10.2.6 Go fonts

Designed by Kris Holmes and Charles Bigelow for the Go project, the Go font families consist of a humanistic sans serif font in three weights and a matching monospaced, slap serif font available in two weights.

Family	Series	Shapes	Typeface Examples
<i>Go Sans</i>	Go Sans	(Encodings: T1, TS1, OT1, LY1, and TU)	
Go-TLF	m	n, it, (sl), sc, scit, (scsl)	Go Sans regular, <i>italic</i> , and <i>SMALL CAPS ITALICS</i>
	sb, b	n, it, (sl)	Go Sans semi-bold <i>and bold italic</i>
<i>Go Mono</i>	Go Mono	(Encodings: T1, TS1, OT1, LY1, and TU)	
GoMono-TLF	m, b	n, it, (sl)	Go Mono regular <i>and bold italic</i>

The supported figure style of the Go Sans and Go Mono fonts is -TLF.

Table 10.7: Classification of the Go font families

Both families have very distinctive forms for zero, capital O, lowercase l, digit one, and capital I, making them very suitable for displaying computer code without the danger of misinterpretations. \LaTeX support for all engines is provided by the packages GoSans and GoMono by Bob Tennent.

<i>Go Sans 10pt/12pt</i> (Go-TLF) Go Sans	With a price of £148, almost anything can be found FLOATING IN Fields . — ¿But aren't Kafka's Schloß & Æsop's Œuvres often <i>naïve</i> vis-à-vis the dæmonic <i>phœnix's official rôle</i> in fluffy soufflés?
<i>Go Mono 9pt/11.5pt</i> (GoMono-TLF) Go Mono	With a price of £148, almost anything can be found Floating In Fields . — ¿But aren't Kafka's Schloß & Æsop's Œuvres often <i>naïve</i> vis-à-vis the dæmonic <i>phœnix's official rôle</i> in fluffy soufflés?

10.2.7 Inria fonts

The Inria families are free fonts designed by the Black foundry for the Inria research institute in France. Offered are a serif and sans serif design in three weights with matching italics. For `\slshape` the italics are substituted; Small Caps are not available. \LaTeX support for the pdf \TeX engine is provided by the packages InriaSerif and InriaSans by Nicolas Markey.

Unicode engines

For Unicode engines use the fontspec package to set up the fonts.

<i>Inria Serif 10pt/12pt</i> (InriaSerif-OsF) Inria Serif	With a price of £148, almost anything can be found Floating In Fields . — ¿But aren't Kafka's Schloß & Æsop's Œuvres often <i>naïve</i> vis-à-vis the dæmonic <i>phœnix's official rôle</i> in fluffy soufflés?
<i>Inria Sans 10pt/12pt</i> (InriaSans-OsF) Inria Sans	With a price of £148, almost anything can be found Floating In Fields . — ¿But aren't Kafka's Schloß & Æsop's Œuvres often <i>naïve</i> vis-à-vis the dæmonic <i>phœnix's official rôle</i> in fluffy soufflés?

Family	Series	Shapes	Typeface Examples
<i>Inria Serif</i>	Inria Serif	(Encodings: T1, TS1, OT1, LY1, and TU)	
InriaSerif-LF	l, m, b	n, it, (sl)	Inria Serif regular and bold italic
	l, m, b	tl, tlit (tlsl)	Also some nonstandard Heavy Shapes
<i>Inria Sans</i>	Inria Sans	(Encodings: T1, TS1, OT1, LY1, and TU)	
InriaSans-LF	l, m, b	n, it, (sl)	Inria Sans regular and bold italic
	l, m, b	tl, tlit (tlsl)	Also some nonstandard Heavy Shapes

Supported figure styles of the Inria Serif and Inria Sans fonts are -LF, -OsF, -TLF, -TosF, and -Sup. Inria Code is offered with -TLF and -TosF.

Table 10.8: Classification of the Inria font families

10.2.8 Kp (Johannes Kepler) fonts

The Kp family of typefaces has been designed by Christophe Caignaert in the first two decades of the 21st century. It was inspired by Hermann Zapf’s (1918–2015) Palatino. Recently Daniel Flipo produced OpenType versions of the fonts, so now they can be used with all engines.

The fonts support both oldstyle and lining numbers. To get oldstyle numerals with pdf_TEX, you need to append osn to the base family name shown in Table 10.9 on the next page; e.g., use jkpxosn. Alternatively, it is possible to select oldstyle numerals as well as two further glyph variations: a swash uppercase Q and rare (historical) ligatures. This is done by appending os instead, and it gives you output such as

Queer, faſt, ſtrange, and ſatisfying aſtions!

It is also possible to select a “very oldstyle” with vos, which is like os but additionally uses a long “f” instead of the normal “s” as well as a special “ft” ligature by default. When you typeset with pdf_TEX, you then get the “short s” through the ligature s=:

Queer, faſt, ftſrange, and faſtifying aſtions!
(written as ...satis=ſfying actions=! this time)

A further differentiator is the support for either petite capitals (the default) or somewhat larger small capitals by appending k to the family name:

PETITE CAPITALS compared to LARGER SMALL CAPITALS

Finally, it is also possible to prevent the use of the usual f-ligatures by appending f, which then gives you

fi ffi ff ffl instead of the usual fi ffi ff ffl.

Family	Series	Shapes	Typeface Examples
<i>Kp Roman</i>	KpRoman	(Encodings: T1, TS1, OT1, and TU)	
jkpx	l, m, sb, sbx, b, bx	n, it, sl, sc, scsl	Light, regular, <i>slanted</i> , <i>italic</i> , semi bold , bold , bold extended & SMALL CAPS with lining numerals 123... (for oldstyle numerals see note)
jkpl	m, b, bx	n, it, sl, sc, scsl	Light, <i>slanted</i> , <i>italic</i> , bold , bold extended & SMALL CAPS with lining numerals 123... (see note)
<i>Kp Sans</i>	KpSans	(Encodings: T1, TS1, OT1, and TU)	
jkpss	m, b, bx	n, (it), sl, sc, scsl	Regular, <i>slanted</i> , bold , bold extended & SMALL CAPS with lining numerals 123... (see note)
<i>Kp Typewriter</i>	KpMono	(Encodings: T1, TS1, OT1, and TU)	
jkptt	m, b	n, (it), sl	Regular, <i>slanted</i> & bold

The NFSS family names shown above are base names. If used with pdfTeX, the fonts use different family names to distinguish oldstyle numerals from lining numerals and the use or absence of special ligatures. See the explanation in the text on how to select the appropriate family names.

Table 10.9: Classification of the Kp font families

The different suffixes can be combined in the following way:

`<base family name><k or missing><f or missing><osn, os, vos or missing>`

For example, jkpxkos gives you larger small capitals as well as all ligatures and oldstyle numbers. There are a few restrictions, though: using f together with os or vos makes little sense, so that is not supported. The typewriter family never has f-ligatures and does not offer small caps, so neither f nor k is available with jkptt. Further explicit examples are shown in the text samples.

Unicode engines

Note that with Unicode engines you use the feature sets of fontspec instead of playing around with different NFSS family names.

Part of this meta family is a full set of matching math fonts that include all math symbols and alphabets from L^AT_EX as well as those from the AMS fonts. Examples with mathematical content are shown in Figures 12.6 to 12.8 on pages 266–267 and for Kepler Sans in Figure 12.47 on page 293.

To use the Kp fonts for both text and math you can use the support package kpfonts (by Christophe Caignaert), when typesetting with pdfTeX, or the package kpfonts-otf (by Daniel Flipo), when using a Unicode engine.

Both packages offer a large number of options that let you select various font features, e.g., light, oldstylenums, oldstyle, largesmallcaps, and many more. You can also use it to only set up text fonts or some of the text fonts with nomath,

onlyrm, nott, and a few more. How to make use of the Kp math fonts, and the support options for them, is covered in Chapter 12.

With a price of £148, **almost anything** can be found FLOATING IN FIELDS. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often naïve vis-à-vis the dæmonic *phænix's official rôle* in fluffy soufflés?

Kp Roman in oldstyle
10pt/12pt
(jkpxos) **KpRoman**

The light face saves about 10% of toner. It prints fine but may be less suited if viewed mainly on screens. Metrically it is identical to the normal weight font (if you keep all other font features identical), so you should not experience different line or page breaks if you change your mind at some point. The only restriction is that unlike the jkpx family it offers only two weights and not four.

With a price of £148, **almost anything** can be found FLOATING IN FIELDS. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often naïve vis-à-vis the dæmonic *phænix's official rôle* in fluffy soufflés?

Kp Roman light 10pt/12pt
(jkpl) **KpRoman**

The Sans family is shown below with the f-ligatures turned off. As with most sans typefaces, italics are really just oblique shapes with otherwise identical design.

With a price of £148, **almost anything** can be found FLOATING IN FIELDS. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often naïve vis-à-vis the dæmonic *phænix's official rôle* in fluffy soufflés?

*Kp Sans without f-ligatures
but larger small capitals*
10pt/12pt
(jkpsskf) **KpSans**

One of the interesting aspects of the Kp typewriter font is that you can have it with oldstyle numerals through the osn. Because typewriter fonts have no ligatures, using the os suffix gives you only the swash Q in addition (as a double-wide character), which is fairly pointless, and getting “long s” in a typewriter font is also questionable.

With a price of £148, **almost anything** can be found *Floating In Fields*. -- ¿But aren't Kafka's Schloß & Æsop's Œuvres often naïve vis-à-vis the dæmonic *phænix's official rôle* in fluffy soufflés?

*Kp Typewriter with oldstyle
numerals 10pt/12pt*
(jkpttosn) **KpMono**

10.2.9 Libertinus — A fork of Linux Libertine and Biolinum

Linux Libertine, designed by Philipp H. Poll, is a transitional serif typeface inspired by 19th century book type and is intended as a replacement for the Times font family. It is available in three weights, each with italics and small capitals. Philipp also designed a complementary humanist sans serif face named Linux Biolinum and a matching monospaced font Linux Libertine Mono.

Work on the fonts ceased in 2003, and afterwards a number of forks appeared that continued the development under new names. Interesting from a L^AT_EX perspective is Libertinus by Khaled Hosny, who also added supporting math fonts. Package support

Family	Series	Shapes	Typeface Examples
<i>Libertinus Serif</i>	Libertinus Serif	(Encodings: T1, TS1, T2A, T2B, T2C, OT1, LGR, LY1, and TU)	
LibertinusSerif-LF	m, sb, b	n, it, (sl), sc, scit, (scsl)	Regular, <i>italic</i> , semi-bold , bold , and SMALL CAPS <i>ITALIC</i>
<i>Libertinus Serif Display</i>	Libertinus Serif Display	(Encodings: T1, TS1, T2A, T2B, T2C, OT1, LGR, LY1, and TU)	
LibertinusSerifDisplay-LF	m	n	Only one weight and shape
<i>Libertinus Sans</i>	Libertinus Sans	(Encodings: T1, TS1, T2A, T2B, T2C, OT1, LGR, LY1, and TU)	
LibertinusSans-LF	m, sb, b	n, it, (sl), sc, scit, (scsl)	Regular, <i>italic</i> , semi-bold , bold , and SMALL CAPS <i>ITALIC</i>
<i>Libertinus Mono</i>	Libertinus Mono	(Encodings: T1, TS1, OT1, LY1, and TU)	
LibertinusMono-TLF	m, b	n, (it), sl	Regular, <i>oblique</i> , bold

Supported figure styles for Libertinus Serif, Serif Display, and Sans are -LF, -OsF, -TLF, -T0sF, and -Sup.
Libertinus Mono is offered with -LTF and -Sup.

Table 10.10: Classification of the Libertinus font families

for this fork¹ is provided through the `libertinus` package by Bob Tennent and Herbert Voß. The package offers options to set up all families or individual ones, scale some of them, select oldstyle figures, etc.

Unicode engines

The Libertinus math fonts are currently supported only by Unicode engines; see Figure 12.23 on page 277 for a sample page. There is, however, also support through Michael Sharpe’s `newtxmath` package, which offers a Libertine version in math, as shown in Figure 12.22 on page 277.

Libertinus Serif 10pt/12pt
(LibertinusSerif-OsF)
Libertinus Serif

With a price of £148, **almost anything** can be found FLOATING IN **FIELDS**. — ¿But aren’t Kafka’s Schloß & Æsop’s Œuvres often *naïve* vis-à-vis the dæmonic *phænix’s official rôle* in fluffy soufflés?

Libertinus Sans 10pt/12pt
(LibertinusSans-OsF)
Libertinus Sans

With a price of £148, **almost anything** can be found FLOATING IN **FIELDS**. — ¿But aren’t Kafka’s Schloß & Æsop’s Œuvres often *naïve* vis-à-vis the dæmonic *phænix’s official rôle* in fluffy soufflés?

Because the monospaced font often appears to be rather large, you may want to use it scaled down.

¹The original fonts are also supported under L^AT_EX through the packages `libertine` and `biolinum`, but for new projects using `libertinus` is the better choice.

With a price of £148, **almost anything** can be found **Floating In Fields**. – ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phœnix's official rôle* in fluffy soufflés?

Libertinus Serif

10.2.10 Lucida fonts

The Lucida extended family of typefaces has been designed by Charles Bigelow and Kris Holmes. Besides being popular choices in computer operating systems, because of their screen legibility, the fonts are also widely used for scientific and technical publishing. Lucida Bright, Lucida Sans, and Lucida Math are the main typeface families used for this book. They are commercial, so you have to buy them, but for a high-quality printout that requires full support for all of L^AT_EX's math capabilities, they are an attractive choice.¹ Table 10.11 on the next page lists all Lucida text² families that are sold as a set by T_EX Users Group. As you will notice, there are some differences in coverage between Type 1 fonts for use with pdfT_EX and Opentype fonts for use with the Unicode engines. Lucida Bright, Lucida Sans, Lucida Sans Typewriter, Lucida Blackletter, Lucida Casual, Lucida Calligraphy, and Lucida Handwriting are available for all engines (though the Opentype versions of the fonts have a far larger glyph coverage, because they are not restricted to 256 glyphs). However, there are also a number of typefaces that are available only in Type 1 for pdfT_EX or only in OpenType format for X_YT_EX or LuaT_EX.

All Lucida font families share common design principles and are intended to be mixed and matched in arbitrary (possibly surprising) ways. In particular, Lucida Bright, Lucida Sans, and Lucida Sans Typewriter are meant to be used in unison, and this is possible in all engines. For pdfT_EX there is the package `lucidabr` that also sets up Lucida Math for you — sample pages with mathematics are shown in Figures 12.24 to 12.26 on pages 278–279. If you want only the text fonts, then altering `\rmdefault`,

¹However, most freestanding math examples in this book are *deliberately not* set in Lucida Math but in Computer Modern Math, because that is what most people are used to seeing. The look and feel is noticeably different between the two, and I wanted the examples to resemble the typical T_EX look with respect to formulas. For the same reason, Latin Modern Typewriter is used for typesetting command names and code.

²The math fonts, which are also part of the set, are covered in Chapter 12.

Family	Series	Shapes	Typeface Examples

Oldstyle numerals as a default are implemented as a second, differently named font family in pdf_T_EX. If you use the hlh family (with lining numerals), you can get them through \oldstylenums. Some of the font families are available only in Type 1 format (for pdf_T_EX); others are available only in OpenType format for Unicode engines (X_T_T_EX or Lua_T_EX).

Table 10.11: Classification of the Lucida font families

`\sfdefault`, or `\ttdefault` is all that is needed as long as you remember to also change the font encoding to T1 or LY1, because none of the fonts is available in OT1.

Unicode engines

In Unicode engines you have to set up the fonts yourself using `fontspec` and `unicode-math`; suitable `.fontspec` files are provided.

10-2-1

With a price of £148, **almost anything** can be found FLOATING IN **FIELDS**. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phænix's official rôle* in fluffy soufflés?

Lucida Bright 9pt/12pt
(hlh) **Lucida Bright OT**

If you prefer oldstyle numerals by default and you typeset with pdfT_EX, use `hlhj` as the family name. With the Unicode engines apply `Numbers=OldStyle` in your `fontspec` declarations instead.

10-2-2

With a price of £148, **almost anything** can be found **Floating In Fields**. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phænix's official rôle* in fluffy soufflés?

Lucida Sans 9pt/12pt
(hls) **Lucida Sans OT**

With a price of £148, **almost anything** can be found **Floating In Fields**. -- ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phænix's official rôle* in fluffy soufflés?

Lucida Sans Typewriter 9pt/12pt
(hlst) **Lucida Sans Typewriter OT**

As you will have observed, the Lucida fonts appear to be rather large (even if set at 9pt, as we did in the above example), and it is important to give them enough leading so that they do not appear cramped. In the book we used an even smaller measure¹ of 8.5pt/11.7pt, which works fine; i.e., it is possible to scale them noticeably down while maintaining a balanced and pleasing look. With pdfT_EX, the method to produce such downscaling is to define the command `\DeclareLucidaFontShape` — the documentation coming with the fonts explains how.

If you prefer a matching typewriter font with serifs, you can use Lucida Typewriter if you typeset with pdfT_EX.

With a price of £148, **almost anything** can be found **Floating In Fields**. -- ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phænix's official rôle* in fluffy soufflés?

Lucida Typewriter 9pt/12pt
(hlct) —no OpenType—

Notice that Lucida Typewriter runs considerably wider than its sans serif counterpart. However, if you place both side by side, you see that their x-heights match. If

¹This is the reason why these examples are not done in-line, but externally. If in-line as most other typeface examples, the fonts would have picked up the scale used for the body fonts of the book.

you use a Unicode engine, then Lucida Typewriter is not available, but there are two further sans serif typewriter alternatives: Lucida Console and Lucida Grande Mono.

Lucida Console 9pt/12pt
(— only OpenType —)
Lucida Console DK

with a price of £148, **almost anything** can be found
Floating In Fields. — ¿But aren't Kafka's Schloß
& Æsop's Œuvres often *naïve* vis-à-vis the dæmonic
phænix's official rôle in fluffy soufflés?

10-2-3

Lucida Grande Mono
9pt/12pt
(— only OpenType —)
Lucida Grande Mono DK

With a price of £148, **almost anything** can be found
Floating In Fields. — ¿But aren't Kafka's Schloß
& Æsop's Œuvres often *naïve* vis-à-vis the dæmonic
phænix's official rôle in fluffy soufflés?

10-2-4

On first glance you may not see any difference, given that both fonts have the same running length and are nearly identical in design. But if you look carefully, you can see that the uppercase letters of Lucida Grande Mono are noticeably taller than those of Lucida Console and that some characters have subtle differences, e.g., the bottoms of the “l” or the italic “i” are rounded in Lucida Grande Mono, while they are straight in Lucida Console.

The “DK” in their names stands for Donald Knuth, who, in a reply to [20], asked for an alternate “squarish” design for O and Q in Lucida Console [98] to make them easier distinguishable from the digit 0. Charles Bigelow acted on his request [21] and produced special versions of his fonts that are available only through TUG. They use Don’s suggested letter forms by default, but also allow you to activate the default designs through the feature set ss01 (which also changes to a slashed zero), and it is also possible to combine the squared O with the slashed zero as shown in the third line of the example. The alternate designs are available in both typefaces.

Q	O	I	l	0	1	1	<code>\usepackage{fontspec}</code>	
Q	O	I	l	0	1	1	<code>\LARGE</code>	
Q	O	I	l	0	1	1	<code>\fontspec{Lucida Console DK}[]</code>	Q O I l 0 1 1 \par
Q	O	I	l	0	1	1	<code>\fontspec{Lucida Console DK}[RawFeature=ss01]</code>	Q O I l 0 1 1 \par
Q	O	I	l	0	1	1	<code>\fontspec{Lucida Console DK}[Numbers=SlashedZero]</code>	Q O I l 0 1 1

10-2-5

The set of Lucida fonts also contains a number of special font faces. Lucida Fax, as the name implies, was originally developed for use in fax transmissions and is very legible in bad reading conditions. This makes it a great choice for small print, e.g., in footnotes (as long as you do not need small capitals). Below we exhibit it in 7pt:

(hlx) Lucida Fax 7pt/9pt
— no OpenType —

With a price of £148, **almost anything** can be found **Floating In Fields.** — ¿But aren't
Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phænix's official rôle*
in fluffy soufflés?

The other four fonts — Lucida Casual, Calligraphy, Handwriting, and Blackletter — all exist in only one weight and only one or two variants, upright and italics. They are

Family	Series	Shapes	Typeface Examples
<i>Merriweather</i>	Merriweather	(Encodings: T1, TS1, OT1, LY1, and TU)	
Merriwthr-OsF	l, m, b, ub	n, it, (sl)	Regular, light, <i>italic</i> , bold , and ultra-bold
<i>Merriweather Sans</i>	Merriweather Sans	(Encodings: T1, TS1, OT1, LY1, and TU)	
MerriwthrSans-OsF	l, m, b, eb	n, it, (sl)	Sans regular, light, <i>italic</i> , bold , and extra-bold

Figure styles are -OsF and -Sup.

Table 10.12: Classification of the Merriweather font families

thus useful only in special circumstances, but all of them can be freely mixed with other Lucida variants.

With a price of £148, *almost anything* can be found *Floating In Fields*. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phœnix's* official rôle in fluffy soufflés?

Lucida Casual 9pt/12pt
(hlcn) — no OpenType —

Both Lucida Calligraphy and Lucida Handwriting appreciate extra leading:

With a price of £148, almost anything can be found Floating In Fields. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phœnix's* official rôle in fluffy soufflés?

Lucida Calligraphy 9pt/13pt
(hlce)
Lucida Calligraphy OT

With a price of £148, almost anything can be found Floating In Fields. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phœnix's* official rôle in fluffy soufflés?

Lucida Handwriting 9pt/13pt
(hlcw)
Lucida Handwriting OT

With pdfTeX, Lucida Blackletter should be primarily used for individual letters in math. As a text typeface (while properly kerned) it is missing the “long s” in that engine, which is needed for setting historically correct type. However, when using one of the Unicode engines, it is available in its appropriate Unicode position U+017F.

With a price of £148, *almost anything* can be found *floating In fields*. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phœnix's* official rôle in fluffy soufflés?

Lucida Blackletter 9pt/12pt
(hlcf)
Lucida Blackletter OT

10.2.11 Merriweather fonts

Designed by Eben Sorkin for Adobe, Merriweather features a large x-height and open letterforms, making it very readable at small sizes. The companion sans serif design Merriweather Sans is semi-condensed. Both families are offered in four weights with

Family	Series	Shapes	Typeface Examples
<i>Droid Serif</i>	Droid Serif	(Encodings: T1, TS1, T2A, T2B, T2C, OT1, LGR, and TU)	
droidserif	m, b	n, it, sl, ui	Serif regular, <i>slanted</i> , <i>italic</i> , bold , and upright italics
<i>Droid Sans</i>	Droid Sans	(Encodings: T1, TS1, T2A, T2B, T2C, OT1, LGR, and TU)	
droidsans	m, b	n, sl, (it)	Sans regular, <i>oblique</i> , bold , and <i>bold oblique</i>
<i>Droid Mono</i>	Droid Sans Mono	(Encodings: T1, TS1, T2A, T2B, T2C, OT1, LGR, and TU)	
droidsansmono	m	n, sl, (it)	Mono regular and <i>oblique</i>

Table 10.13: Classification of the Google Droid font families

upright and italic shapes. Note that Merriweather has ultra-bold (ub), while the Sans has a somewhat lighter extra-bold (eb) series.

LaTeX support for all engines is provided through the package merriweather by Bob Tennent, which offers various options to set up different aspects of the fonts.

<i>Merriweather 9pt/12pt</i> (Merriwthr-OsF) Merriweather	With a price of £148, almost anything can be found FLOATING IN FIELDS . — ¿But aren’t Kafka’s Schloß & Æsop’s Œuvres often <i>naïve</i> vis-à-vis the dæmonic <i>phænix’s official rôle</i> in fluffy soufflés?
<i>Merriweather Sans 9pt/12pt</i> (MerriwthrSans-OsF) MerriweatherSans	With a price of £148, almost anything can be found FLOATING IN FIELDS . — ¿But aren’t Kafka’s Schloß & Æsop’s Œuvres often <i>naïve</i> vis-à-vis the dæmonic <i>phænix’s official rôle</i> in fluffy soufflés?

10.2.12 Google’s Noto and Droid fonts

The Noto family of fonts are Google’s attempt to eventually provide glyph coverage for all languages and scripts defined by the Unicode standard. Right now it consists of more than 100 individual fonts with a total of nearly 64000 characters covering most (though clearly not all, given that Unicode 14 has more than twice the number of defined characters) scripts in their entirety.¹ Besides the goal of full coverage, Noto is designed to provide visual harmony across multiple languages/scripts (e.g., compatible heights and stroke thicknesses) allowing the different Noto fonts to be easily used together.

<i>Noto is normally preferable over Droid</i>	The Latin, Greek, and Cyrillic glyphs in the Noto fonts are derived from the Droid family designed by Steve Matteson — an earlier commission by Google for the Android operating system. They are in fact the Droid fonts, but with additional weights, real small capitals, a greater glyph coverage (e.g., full polytonic Greek), and some errors corrected.
---	--

¹When computer programs, such as browsers, cannot represent glyphs because they are missing in the current font, they often display a little rectangle. These rectangles got nicknamed “tofu” in some circles, and Noto aims to remove the tofu from the Web, hence the name **No tofu**.

To use Droid with the pdfTeX engine, the packages `droid`, `droidmono`, `droidsans`, and `droidserif` by Mohamed El Morabity are available. Except for `droid`, the packages accept the option `scaled` to specify a scale factor when loading individual fonts.

Unicode engines

For Unicode engines you have to set up Droid using the `fontspec` package. But if you use such an engine, then Noto is the better choice, as it simply offers more extensive glyph support and additional weights and shapes throughout.

TeX support for Noto for all engines is provided through the packages `noto`, `noto-mono`, `noto-sans`, and `noto-serif` by Bob Tennent, which support the typical options such as `scaled` or `oldstyle` as well as some special ones to access the huge number of weights offered by the Noto families.¹ The condensed faces have their own support packages `notocondensed` (for Serif and Sans) and `notocondensed-mono`. Because of their size, the condensed fonts are not automatically included in the TeX Live distribution but need a simple manual installation. Follow the instructions at <https://contrib.texlive.info/> for that or download the package from CTAN.

Note that because of their size, the Noto condensed faces need a manual installation

The Droid fonts do not support `\scshape`, whereas Noto has real small capitals that look rather nice. This means that one should normally prefer Noto over Droid unless oblique shapes in addition to italics are needed as those are offered only by Droid. For comparison we show both Droid Serif and Noto Serif below so that you can study the differences:

With a price of £148, **almost anything** can be found **Floating In Fields**. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phœnix's official rôle* in fluffy soufflés?

Droid Serif 10pt/12pt
(droidserif) Droid Serif

With a price of £148, **almost anything** can be found **FLOATING IN FIELDS**. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phœnix's official rôle* in fluffy soufflés?

Noto Serif 10pt/12pt
(NotoSerif-OsF) Noto Serif

The Noto families are available in four running lengths: besides a regular version, there exist three condensed versions that can easily be made the default by using the package `notocondensed` and passing the options `semicondensed`, `condensed`, or `extracondensed`. You can also request a condensed version for only Noto Serif or Sans through `rm` and `sf` or prevent that Noto Sans Mono is used with `nott`. As usual, several other options and commands exist for specialized requirements. Below are the condensed variants of the Serif family — notice how we gradually get more and more words into the lines:

With a price of £148, **almost anything** can be found **FLOATING IN FIELDS**. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phœnix's official rôle* in fluffy soufflés?

Noto Serif (option
semicondensed) 10pt/12pt
(NotoSerif-OsF) Noto Serif Semi Condensed

¹ Noto is one of the few families that supports a huge number of the NFSS series combinations, as it has weights from ultra-light to extra-bold and three compressed versions on top of the regular one; see Tables 10.14 and 10.15 on pages 28–29 for the full setup.

Family	Series	Shapes	Typeface Examples
<i>Noto Serif</i>	<i>Noto Serif</i> (Encodings: T1, TS1, T2A, T2B, T2C, OT1, LGR, LY1, and TU)		
NotoSerif-LF	ul, el, l, sl, m, sb, b, eb, ub	n, it, (sl), sc, scit, (scsl)	Serif regular, <i>italic</i> , bold , and SMALL CAPS

	NotoSansMono-TLF	ul, el, l, sl, m, sb, b, eb, ub	n, sc Sans Mono regular, thin, bold , and black
	Noto Sans Mono Semi Condensed	ulsc, elsc, lsc, slsc, sc, sb, bsc, ebsc, ubsc	n, sc Sans Mono semi-condensed, thin, bold , and black
	Noto Sans Mono Condensed	ulc, elc, lc, slc, c, sb, bc, ebc, ubc	n, sc Sans Mono condensed, thin, bold , and black
	Noto Sans Mono Extra Condensed	ulec, elec, lec, slec, ec, sbec, bec, ebec, ubec	n, sc Sans Mono extra-condensed, thin, bold , and black

Supported figure styles of the SansMono are -TLF and -Sup.

Table 10.15: Classification of the Google Noto font families (cont.)

Here we exhibit all sans serif width variants with their different running lengths from regular down to extra-condensed.

With a price of £148, **almost anything** can be found FLOATING IN **FIELDS**. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phænix's official rôle* in fluffy soufflés?

With a price of £148, **almost anything** can be found FLOATING IN **FIELDS**. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phænix's official rôle* in fluffy soufflés?

With a price of £148, **almost anything** can be found FLOATING IN **FIELDS**. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phænix's official rôle* in fluffy soufflés?

With a price of £148, **almost anything** can be found FLOATING IN **FIELDS**. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phænix's official rôle* in fluffy soufflés?

Noto Sans 10pt/12pt
(NotoSans-OsF) *Noto Sans*

Noto Sans (option semicondensed) 10pt/12pt
(NotoSans-OsF) *Noto Sans Semi Condensed*

Noto Sans (option condensed) 10pt/12pt
(NotoSans-OsF) *Noto Sans Condensed*

Noto Sans (option extracondensed) 10pt/12pt
(NotoSans-OsF) *Noto Sans Extra Condensed*

The Noto Serif and Sans families both have matching math fonts, which are exhibited in Figure 12.38 on page 287 (Noto Serif) and Figure 12.50 on page 295 (Noto Sans). They have been prepared by Michael Sharpe.

Noto Sans Mono is also offered in four different running lengths, and if you want to use one of the condensed faces together with some other font families, use notocondensed-mono for setup. These condensed versions are a great choice if you have tight spacing requirements as even the extra-condensed version is very readable.

Noto Sans Mono 9pt/12pt
(NotoSansMono-TLF)
Noto Sans Mono

With a price of £148, **almost anything** can be found
FLOATING IN **FIELDS**. – ¿But aren't Kafka's Schloß &
Æsop's Œuvres often naïve vis-à-vis the dæmonic phoenix's
official rôle in fluffy soufflés?

For comparison here is the extra-condensed version of Noto Sans Mono, which shows that you can save quite a lot of space when using it:

*Noto Sans Mono (option
extracondensed) 9pt/12pt*
(NotoSansMono-TLF)
Noto Sans Mono
Extra Condensed

With a price of £148, **almost anything** can be found FLOATING IN
FIELDS. – ¿But aren't Kafka's Schloß & Æsop's Œuvres often naïve
vis-à-vis the dæmonic phoenix's official rôle in fluffy soufflés?

However, Noto Sans Mono has neither italics nor oblique shapes, but it does offer different weights, which is perhaps more important. Droid Sans Mono on the other hand has no bold but offers italics. Thus, which to deploy depends on your use case.

Droid Mono 9pt/12pt
(droidsansmono)
Droid Sans Mono

With a price of £148, **almost anything** can be found
Floating In **Fields**. – ¿But aren't Kafka's Schloß &
Æsop's Œuvres often naïve vis-à-vis the dæmonic phoenix's
official rôle in fluffy soufflés?

10.2.13 IBM Plex

The IBM Plex families have been developed by Mike Abbink at IBM in collaboration with Bold Monday and others with the intention to represent the IBM Brand spirit. Each family is offered in eight different weights with upright and italic shapes. Small capitals are not supported, and \slshape is aliased to italics.

IBM Plex Serif was inspired by Bodoni and Janson and incorporates oldstyle and Didone design aspects. IBM Plex Sans is a grotesque sans serif typeface with a design that was inspired by Franklin Gothic. It also exists in a condensed version offering all weights and shapes and can thus be used as a drop-in replacement for the regular sans serif. The letter forms of IBM Plex Mono upright are based on Plex Sans, while its italic shape was inspired by an italic typeface used on IBM's Selectric typewriter (one with a typeball).

LaTeX support for all engines is provided by the packages plex-serif, plex-sans, and plex-mono by Bob Tennent with the usual options for selecting the weights or a scaling factor (scaled).

Family	Series	Shapes	Typeface Examples
<i>IBM Plex Serif</i>	IBM Plex Serif (Encodings: T1, TS1, OT1, LY1, and TU)		
IBMPlexSerif-TLF	ul, el, l, m, sb, b	n, it, (sl)	IBM Plex Serif, <i>italic</i> , bold , and light
<i>IBM Plex Sans</i>	IBM Plex Sans, IBM Plex Sans Condensed (Encodings: T1, TS1, OT1, LY1, and TU)		
IBMPlexSans-TLF	ul, el, l, sl, m, sb, b ulc, elc, lc, slc, c, sbc, bc	n, it, (sl)	IBM Plex Sans, <i>italic</i> , bold , light, and thin Condensed Sans <i>italic</i> , bold , light, and thin
<i>IBM Plex Mono</i>	IBM Plex Mono (Encodings: T1, TS1, OT1, LY1, and TU)		
IBMPlexMono-TLF	ul, el, l, sl, m, sb, b	n, it, (sl)	IBM Plex Mono, <i>italic</i> , and bold

Supported figure styles of the IBM Plex fonts are -TLF and -Sup.

Table 10.16: Classification of the IBM Plex font families

With a price of £148, almost anything can be found Floating In Fields . — ¿But aren't Kafka's Schloß & Æsop's Œuvres often <i>naïve</i> vis-à-vis the dæmonic <i>phænix's official rôle</i> in fluffy soufflés?	<i>Plex Serif 10pt/12pt</i> (IBMPlexSerif-TLF) IBM Plex Serif

10.2.14 PT fonts

Paratype PT fonts have been designed by Alexandra Korolkova with assistance from Olga Umpeleva and Vladimir Yefimov. They consist of a humanistic sans serif, a serif, and a monospaced font all available in regular and bold weights. All fonts offer a wide glyph range and thus are capable of typesetting text in most Latin and Cyrillic languages.

Family	Series	Shapes	Typeface Examples
<i>PT Serif</i>	PT Serif	(Encodings: T1, TS1, T2A, T2B, T2C, OT1, and TU)	
PTSerif-TLF	m, b	n, it, sl	PT Serif regular, <i>slanted</i> , <i>italic</i> , bold , and <i>bold italic</i>
<i>PT Sans</i>	PT Sans	(Encodings: T1, TS1, T2A, T2B, T2C, OT1, and TU)	
PTSans-TLF	m, b	n, it, (sl)	PT Sans regular, <i>italic</i> , bold , and <i>bold italic</i>
	c, bc	n	PT Sans narrow and narrow bold
<i>PT Sans Narrow</i>	PT Sans Narrow	(Encodings: T1, TS1, T2A, T2B, T2C, OT1, and TU)	
PTSansNarrow-TLF	m, b	n, sl	PT Sans Narrow, <i>oblique</i> , bold , and <i>bold oblique</i>
<i>PT Serif Caption</i>	PT Serif Caption	(Encodings: T1, TS1, T2A, T2B, T2C, OT1, and TU)	
PTSerifCaption-TLF	m	n, it, sl	PT Serif Caption, <i>italic</i> , <i>slanted</i> , bold , and <i>bold italic</i>
<i>PT Sans Caption</i>	PT Sans Caption	(Encodings: T1, TS1, T2A, T2B, T2C, OT1, and TU)	
PTSansCaption-TLF	m, b	n, sl	PT Sans Caption, <i>oblique</i> , bold , and <i>bold oblique</i>
<i>PT Mono</i>	PT Mono	(Encodings: T1, TS1, T2A, T2B, T2C, OT1, and TU)	
PTMono-TLF	m, b	n, sl	PT Mono regular, <i>oblique/slanted</i> , bold , and <i>bold oblique</i>

Table 10.17: Classification of the Paratype PT font families

Most of the slanted shapes are mechanically generated and are therefore of a somewhat lesser quality; however, when used only occasionally, they should work well enough.

Support for the pdfTeX engine is provided by Pavel Farář through the paratype bundle that contains the packages PTSerif, PTSerifCaption, PTSans, PTSansCaption, PTSansNarrow, and PTMono. All of them support the option `scaled` to specify a scale factor when loading individual fonts and set the corresponding family up as the default serif, sans serif, or typewriter font.

Unicode engines

For Unicode engines you have to set them up using the `fontspec` package.

PT Serif 10pt/12.6pt
(PTSerif-TLF) **PT Serif**

With a price of £148, **almost anything** can be found **Floating In Fields**. — ¿But aren’t Kafka’s Schloß & Æsop’s Œuvres often *naïve* vis-à-vis the dæmonic *phœnix’s official rôle* in fluffy soufflés?

PT Sans 10pt/12.6pt
(PTSans-TLF) **PT Sans**

With a price of £148, **almost anything** can be found **Floating In Fields**. — ¿But aren’t Kafka’s Schloß & Æsop’s Œuvres often *naïve* vis-à-vis the dæmonic *phœnix’s official rôle* in fluffy soufflés?

Family	Series	Shapes	Typeface Examples
<i>Quattrocento</i>	Quattrocento	(Encodings: T1, TS1, OT1, LY1, and TU)	
Quattro-LF	m, b	n, (it), sl	Quattrocento regular, <i>oblique</i> , bold , and <i>bold oblique</i>
<i>Quattrocento Sans</i>	Quattrocento Sans	(Encodings: T1, TS1, OT1, LY1, and TU)	
QuattroSans-LF	m, b	n, (it), sl	Quattrocento Sans regular, <i>oblique</i> , bold , and <i>bold oblique</i>

Supported figure styles for the Quattrocento families are -LF and -Sup.

Table 10.18: Classification of the Quattrocento font families

The monospaced family has oblique shapes but not italics nor any small capitals:

With a price of £148, **almost anything** can be found **Floating In Fields**. – ¿But aren't Kafka's Schloß & Æsop's Œuvres often naïve vis-à-vis the dæmonic *phænix's official rôle* in fluffy soufflés?

PT Mono 8pt/10pt
(PTMono-TLF) PT Mono

PT Sans also exists in a narrow version for documents that have tight spacing requirements. Note, however, that for this version no italic shape has been set up.

With a price of £148, **almost anything** can be found **Floating In Fields**. – ¿But aren't Kafka's Schloß & Æsop's Œuvres often naïve vis-à-vis the dæmonic *phænix's official rôle* in fluffy soufflés?

PT Sans Narrow 10pt/12.6pt
(PTSansNarrow-TLF)
PT Sans Narrow

Finally, both PT Serif and PT Sans have a Caption variant for typesetting in small type, e.g., credentials or captions in small size, hence the name.

With a price of £148, **almost anything** can be found **Floating In Fields**. – ¿But aren't Kafka's Schloß & Æsop's Œuvres often naïve vis-à-vis the dæmonic *phænix's official rôle* in fluffy soufflés?

PT Serif Caption 7pt/10pt
(PTSerifCaption-TLF)
PT Serif Caption

Note, however, that with PT Serif Caption there is no bold weight, and with PT Sans Caption you do not get any italics (`\textsl` works, though).

With a price of £148, **almost anything** can be found **Floating In Fields**. – ¿But aren't Kafka's Schloß & Æsop's Œuvres often naïve vis-à-vis the dæmonic *phænix's official rôle* in fluffy soufflés?

PT Sans Caption 7pt/10pt
(PTSansCaption-TLF)
PT Sans Caption

10.2.15 Quattrocento

Quattrocento, designed by Pablo Impallari, is a typeface with wide and open letterforms and a large x-height, making it very legible at small sizes. It is offered in two weights and upright and oblique shapes. Quattrocento Sans is the matching sans serif design.

L^AT_EX support for all engines is provided through the `quattrocento` package by Bob Tennent, which sets up one or both families based on options.

Quattrocento 9pt/11pt
(`Quattro-LF`)
`Quattrocento`

With a price of £148, **almost anything** can be found [Floating In Fields](#). —
¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic
phœnix's official rôle in fluffy soufflés?

Quattrocento Sans 9pt/11pt
(`QuattroSans-LF`)
`Quattrocento Sans`

With a price of £148, **almost anything** can be found [Floating In Fields](#). —
¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic
phœnix's official rôle in fluffy soufflés?

10.2.16 Google Roboto families

Roboto, designed by Christian Robertson for Google, is a neo-grotesque sans serif typeface. It has been used as the operating system font for Android since 2011 (replacing Droid) and several of Google's web applications, which contributed to its growing popularity. The companion monospaced font is Roboto Mono. Roboto is offered in six weights and three condensed cuts and Roboto Mono in five weights each time with upright and oblique shapes. Roboto Slab is a slab serif font based on Roboto. It comes in four weights but only in upright shape.

L^AT_EX support for all engines is provided by Bob Tennent through the packages `roboto` and `roboto-mono` supporting the usual options, such as `scaled`, various figure styles, and weight selections.

Roboto 10pt/12pt
(`Roboto-OfF`) `Roboto`

With a price of £148, **almost anything** can be found **FLOATING IN FIELDS**. —
¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic
phœnix's official rôle in fluffy soufflés?

To use the Roboto Condensed font as the default sans serif font in your document you can pass the option `condensed` to the `roboto` package. Alternatively, you can select it individually through the `c` font series.

Roboto (option condensed)
10pt/12pt (Roboto-OfF)
`Roboto Condensed`

With a price of £148, **almost anything** can be found **FLOATING IN FIELDS**. —
¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic
phœnix's official rôle in fluffy soufflés?

Note that the Small Caps in both Roboto Mono and Roboto Slab make no distinction between upper and lowercase as you can see below:

Roboto Mono 9pt/12pt
(`RobotoMono-TLF`)
`Roboto Mono`

With a price of £148, **almost anything** can be found **FLOATING IN FIELDS**. —
¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phœnix's official rôle* in fluffy soufflés?

Family	Series	Shapes	Typeface Examples
<i>Roboto</i>	Roboto, Roboto Condensed	(Encodings: T1, TS1, OT1, LGR, LY1, and TU)	
Roboto-LF	el, l, m, sb, b, eb	n, (it), sl, sc, (scit), scsl	Roboto regular, <i>oblique</i> , bold , and SMALL CAPS OBLIQUE
	lc, c, bc	n, (it), sl, sc, (scit), scsl	Condensed, <i>oblique</i> , bold , and light
<i>Roboto Slab</i>	Roboto Slab	(Encodings: T1, TS1, OT1, LGR, LY1, and TU)	
RobotoSlab-TLF	el, l, m, b	n	Roboto Slab regular, <i>thin</i> , and bold
<i>Roboto Mono</i>	Roboto Mono	(Encodings: T1, TS1, OT1, LGR, LY1, and TU)	
RobotoMono-TLF	el, l, m, sb, b	n, it, (sl), sc, scit, (scsl)	Roboto Mono <i>oblique</i> , SMALL CAPS , and bold

Supported figure styles for Roboto and Roboto Condensed are -LF, -OsF, -TLF, and -T0sF. Roboto Mono and Roboto Slab offer only -TLF figures. LGR is not fully provided: the families offer only monotonic Greek. Roboto Mono's italic shape is in reality oblique. Also note that in the sc shape all letters have the same height.

Table 10.19: Classification of the Roboto font families

With a price of £148, **almost anything** can be found **FLOATING IN FIELDS**. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phoenix's official rôle* in fluffy soufflés?

Roboto Slab Serif (option `rm`)
10pt/13pt
(RobotoSlab-TLF)
Roboto Slab

To set up the Roboto Slab font as the default roman font, pass the option `rm` to the `roboto` package. It does not happen automatically as you may want to combine Roboto Sans with some other serif font.

10.2.17 Adobe Source Pro

Adobe's Source Serif Pro, designed by Frank Griefßhammer, is a typeface inspired by the work of Pierre-Simon Fournier. The companion sans serif font Source Sans Pro and the monospaced Source Code Pro were designed by Paul D. Hunt. Source Sans Pro is inspired by typefaces by Morris Fuller Benton (1872–1948), such as Franklin Gothic, but with larger x-height and Humanist-influenced italics. The italics for Source Code Pro got added later by Teo Tuominen.

L^AT_EX support for all engines is provided by Silke Hofstra through the three packages `sourceserifpro`, `sourcesanspro`, and `sourcecodepro`; for options see the package documentation.

With a price of £148, **almost anything** can be found **FLOATING IN FIELDS**. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phoenix's official rôle* in fluffy soufflés?

Source Serif Pro 10pt/12pt
(SourceSerifPro-OsF)
Source Serif Pro

Family	Series	Shapes	Typeface Examples
<i>Adobe Source Serif Pro</i>	Source Serif Pro	(Encodings: T1, TS1, OT1, LY1, and TU)	
SourceSerifPro-LF	el, l, m, sb, b, k	n, it, (sl), sc	Source Serif Pro regular and bold italic
<i>Adobe Source Sans Pro</i>	Source Sans Pro	(Encodings: T1, TS1, OT1, LY1, and TU)	
SourceSansPro-LF	el, l, m, sb, b, k	n, it, (sl), sc	Source Sans Pro regular and bold italic
<i>Adobe Source Code Pro</i>	Source Code Pro	(Encodings: T1, TS1, T2A, T2B, T2C, OT1, LY1, and TU)	
SourceCodePro-TLF	el, l, m, mb, sb, b, k	n, it, (sl)	SourceCodePro and bold italic

Supported figure styles of the Source Serif Pro and Source Sans Pro fonts are -LF, -OsF, -TLF, -TOf, and -Sup. Source Code Pro supports only -TLF, -TOf, and -Sup and the Cyrillic encodings only in upright shape but not in italics! k (black) is a nonstandard series name for eb (extra bold) or in some families for ub (ultra bold).

Table 10.20: Classification of the Adobe SourceCode font families

<i>Source Sans Pro 10pt/12pt</i> (SourceSansPro-OsF) Source Sans Pro	With a price of £148, almost anything can be found FLOATING IN FIELDS . — ¿But aren't Kafka's Schloß & Æsop's Œuvres often <i>naïve</i> vis-à-vis the dæmonic <i>phœnix's</i> official rôle in fluffy soufflés?
<i>Source Code Pro 9pt/11pt</i> (SourceCodePro-TLF) Source Code Pro	With a price of £148, almost anything can be found Floating In Fields . — ¿But aren't Kafka's Schloß & Æsop's Œuvres often <i>naïve</i> vis-à-vis the dæmonic <i>phœnix's</i> official rôle in fluffy soufflés?

10.3 Humanist (Oldstyle) serif fonts

Historically, Humanist or Renaissance typefaces are the earliest fonts following the Blackletter types used by Gutenberg and other early printers. They mimic Latin handwriting and started to appear in the middle of the 15th century in places like Venice and Florence. Primarily they are very calligraphic in nature, which shows in the strongly leftward axis most apparent in the bowls of characters and the lowercase o but often also in an angled e. Other defining characteristics include a small x-height and a fairly low contrast between thick and thin strokes.

Of course, Humanist typefaces do not need to come from that time period: modern designers also picked up the concepts and produced original designs in the Humanist spirit. Centaur, for example, was designed in 1916, and below we show the recent Coelacanth inspired by it.

Few fonts in that style are freely available, but the selection widens considerably if you also look at commercially sold ones. All commercial fonts can be used with Unicode engines with the help of the fontspec package, assuming that you buy the OpenType or TrueType versions. Using them with pdfTeX is less straightforward — you need to take a look at the autoinst program for that.

Family	Series	Shapes	Typeface Examples
<i>Coelacanth</i>	Coelacanth	(Encodings: T1, TS1, OT1, LY1, and TU)	
Coelacanth-LF	m	n, it, (sl), sc, scit, (scsl)	Coelacanth regular, <i>italic</i> , and SMALL CAPS
	el, l, sb, b, eb	n, (it), sc	Thin, light, semi-bold, bold , and heavy

Supported figure styles for Coelacanth are -LF, -0sF, -TLF, and -T0sF. Italic shape is always medium weight!

Table 10.21: Classification of the Coelacanth font family

In the following sections we show three free high-quality typefaces that have been set up for use with L^AT_EX. None of them has oblique shapes (italics are substituted if you ask for them), but that is not surprising because slanted or oblique is a more recent invention and not really in spirit with such typefaces.

10.3.1 Alegreya

Alegreya has a matching sans serif design. Both families are described on page 11, and their NFSS classifications are in Table 10.2 on the same page.

With a price of £148, **almost anything** can be found FLOATING IN **FIELDS**.
 — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the
 dæmonic *phænix's official rôle* in fluffy soufflés?

Alegreya 10pt/12pt
 (Alegreya-0sF)
 Alegreya Sans

10.3.2 Coelacanth

Designed by Ben Whitmore, Coelacanth is inspired by the classic Centaur Type design of Bruce Rogers (1870–1957). It is one of the few Humanist serif families freely available for use with L^AT_EX. The family provides six weights. However, the italics are available only in medium weight and are used unchanged in other weights as well in the L^AT_EX setup. Support for all engines is provided through the package coelacanth by Bob Tennent.

With a price of £148, **almost anything** can be found FLOATING IN **FIELDS**.
 — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the
 dæmonic *phænix's official rôle* in fluffy soufflés?

Coelacanth 10pt/12pt
 (Coelacanth-0sF)
 Coelacanth

10.3.3 fbb — A version of Cardo

Cardo is a Humanist font by David J. Perry that is based on a Venetian type from the 15th century, which was also used as the basis for Monotype's commercial Bembo family. It was developed as part of the Medieval Unicode Font Initiative.

Family	Series	Shapes	Typeface Examples
<i>Cardo</i>	<code>fbf</code> , <i>Cardo</i>	(Encodings: T1, TS1, OT1, LY1, and TU)	
<code>fbf-LF</code>	<code>m</code> , <code>b</code>	<code>n</code> , <code>it</code> , <code>(sl)</code> , <code>sc</code> , <code>scit</code> , <code>(scsl)</code>	Cardo regular, <i>italic</i> , bold , <i>bold italic</i> , <small>SMALL CAPS</small> , <small><i>SMALL CAPS ITALIC</i></small> and <small><i>SMALL CAPS ITALIC BOLD</i></small>

Supported figure styles for *fbf* are `-LF`, `-OfF`, `-TLF`, `-TOsF`, `-Sup`, and `-Inf`.

Table 10.22: Classification of *fbf* (Cardo) font family

Unicode engines

The font is freely available on the Web in TrueType format (but not included in standard T_EX distributions in that form). It contains more than 3 000 glyphs and ligatures covering many modern, classical, and medieval languages. It also supports other rather specialized applications such as historical Greek music notation, phonetic alphabets, and much more. In this form it is available only for Unicode engines.

Starting from the Cardo font, Michael Sharpe produced a version under the name “fbf” but with many modifications, e.g., adding bold italic, Small Caps, and different figure styles. However, his fonts provide only a more restricted glyph set, but still a set of roughly 1 000 characters each. Support for pdfT_EX is provided through the package *fbf*, which accepts typical options such as `scaled` for a scale factor, `oldstyle`, `lining`, etc. You can also supply the option `altP` to use the historically correct open form of “P” instead of the more modern closed rendering “P” usually used — a tiny but interesting detail.

Unicode engines

For Unicode engines a `fontspec` configuration file is provided.

Cardo 10pt/12pt
(`fbf-OfF`) *fbf* With a price of £148, **almost anything** can be found FLOATING IN **FIELDS**. — ¿But aren’t Kafka’s Schloß & Æsop’s Œuvres often *naïve* vis-à-vis the dæmonic *phænix’s official rôle* in fluffy soufflés?

10.4 Garalde (Oldstyle) serif fonts

Named after two influential type designers from the period, Claude Garamond (1499–1561) and Aldus Manutius (1449–1515), Garalde fonts first appeared at the end of the 15th century. There is now less calligraphic influence because typesetting began to be viewed as different from writing. Still, we do have a tilted axis in many characters, but it is subtler and less obvious than in Humanist typefaces. The serifs become more carefully formed and on ascenders more wedge shaped. Characters are designed more proportionally, and there is now a greater contrast between thick and thin strokes.

Family	Series	Shapes	Typeface Examples
<i>Accanthis</i>	<code>Accanthis</code>	(Encodings: T1, TS1, OT1, LY1, and TU)	
<code>AccanthisADFStdNoThree-LF</code>	m, b	n, it, (sl)	Accanthis regular, <i>italic</i> , bold , and <i>bold italic</i>
<i>The supported figure style for Accanthis is -LF.</i>			

Table 10.23: Classification of the Accanthis Font family

Generally speaking we start to see more refinement and details in the characters, in parts surely augmented by the improving skills of the punch cutters of that time. Another difference is the crossbar on the e, which is now fully straight while in Humanist typefaces it was typically sloped.

The number of free high-quality Galalde typefaces prepared for use with \LaTeX is still fairly small; below we show most of them.

10.4.1 Accanthis

The Accanthis family by Hirwen Harendal, which also incorporates some aspects of Humanist fonts (e.g., the tilted e), is suitable as an alternative to fonts such as Garamond, Galliard, and similar Galalde designs. It is offered in two weights with upright and italic characters. \LaTeX support for all engines is provided through the package `accanthis` by Bob Tennent. The option `scaled` lets you select a scaling factor.

With a price of £148, **almost anything** can be found [Floating In Fields](#). — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phoenix's official rôle* in fluffy soufflés?

[Accanthis 10pt/12pt](#)
(`AccanthisADFStdNoThree-LF`)
`Accanthis ADF Std No3`

10.4.2 GFS Artemisia

GFS Artemisia is a slightly calligraphic general-purpose typeface designed by Takis Katsoulidis. \LaTeX support for pdf \TeX is provided through the package `gfsartemisia`, which sets the font up as `\rmdefault` and uses the `txfonts`¹ for formulas. Alternatively, with the package `gfsartemisia-euler` it uses the `euler` package instead. Besides Latin languages, the family fully supports polytonic Greek.

With a price of £148, **almost anything** can be found [FLOATING IN Fields](#). — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phoenix's official rôle* in fluffy soufflés?

[GFS Artemisia 10pt/12pt](#)
(`artemisia`)
`GFS Artemisia`

¹Please note that the `txfonts` have spacing problems and cannot be really recommended; see Section 12.3.4 on page 243 for details. We therefore recommend to use either the `gfsartemisia-euler` package or set up the font manually and add suitable math fonts with the help of the `newtxmath` package.

Family	Series	Shapes	Typeface Examples
<i>GFS Artemisia</i>	GFS Artemisia	(Encodings: T1, OT1, LGR, and TU)	
artemisia	m, b	n, it, sl, sc, sco	Artemisia regular, bold , <i>italic</i> , <i>oblique</i> , and <small>SMALL CAPS OBLIQUE</small>

*The supported figure style for GFS Artemisia is -TLF (but not called this).
Unfortunately, sco is a nonstandard shape name for scsl; thus, low-level shape commands are needed to access it.*

Table 10.24: Classification of the GFS Artemisia font family

Cochineal-LF	m, b	n, it, (sl), sw, sc, scit, (scsl)	Cochineal regular, <i>italic</i> , bold , and <small>SMALL CAPS ITALIC</small>

Supported figure styles for Crimson Pro and Cochineal are -LF, -0sF, -TLF, -T0sF, -Sup, and -Inf.

Table 10.25: Classification of the Crimson Pro/Cochineal font families

10.4.3 Crimson, Crimson Pro, and Cochineal

The Crimson family of fonts has been designed by Sebastian Kosch in the tradition of beautiful Garalde oldstyle typefaces, such as Jan Tschichold’s (1902–1974) Sabon or Robert Slimbach’s Minion. Provided are upright and italic shapes in three weights. The family got extended by Jacques Le Bailly under the name Crimson Pro to cover a total of seven weights from thin to black; also oldstyle figures got added. Support for all TeX engines is provided by Bob Tennent through the package `CrimsonPro`.
Michael Sharpe also extended the Crimson fonts by providing roughly 1500 additional glyphs (including polytonic Greek) so that all glyphs are available in all styles including bold Small Caps and different types of figures (the original Crimson had only lining tabular figures). This extension is distributed as Cochineal fonts, and the L^AT_EX support package is called `cochineal`. Thus, his package is the better choice if you want small capitals or need Greek. The family also has matching mathematical fonts exhibited in Figure 12.2 on page 263.

Cochineal 10pt/12pt

phoenix's official rôle in fluffy soufflés?

Crimson Pro 10pt/12pt
(CrimsonPro-OsF)
Crimson Pro

10.4.4 Cormorant Garamond

Cormorant Garamond, designed by Christian Thalmann, is inspired by Claude Garamond's work but not explicitly based on a particular set of specimens. Its intended usage is that of a display typeface, which is quite visible if set in normal body size because it then appears to be extremely light. Here is an example of regular and light weights at 20 points:

Cormorant Garamond
20pt/24pt
(CormorantGaramond-OsF)
Cormorant Garamond

Cormorant Garamond regular and light

Compare this to the following example showing the regular weight at ten points. In this setting, it appears to be extremely light.

Cormorant Garamond

;But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic
phoenix's official rôle in fluffy soufflés?

ℒ_{AT}_EX support for all engines is available with the `CormorantGaramond` package by Bob Tennent providing the usual options such as `scaled` or `oldstyle`, etc.

10.4.5 EB Garamond

EB Garamond, designed by Georg Duffner and Octavio Pardo, is one of the revivals of the fonts designed by Claude Garamond (1499-1561). The source for the letterforms is a scan of a text known as the “Egenolff-Berner specimen”, composed in the 16th century by Conrad Berner at the Egenolff print office, showing Garamond's roman

Family	Series	Shapes	Typeface Examples
<i>EBGaramond</i>	EBGaramond	(Encodings: T1, TS1, OT1, LY1, and TU)

phænix’s official rôle in fluffy soufflés?

10.4.6 Garamond Libre

The Garamond Libre fonts are an extended fork by D. Benjamin Miller from fonts originally developed by George Douros. They are another Garamond revival with the roman face following Claude Garamond’s (1499–1561) original design. The italics are from a 16th-century engraver too — not Garamond’s (no specimens have survived) but that of Robert Granjon (1513–1589). The upright Greek that is included in the OpenType fonts follow a design by Firmin Didot (1764–1836), while the Greek italics are based on a design by Alexander Wilson (??–1784).

The fonts include support for Latin, Greek, and Cyrillic scripts, and if used with Unicode engines, you can also use the full IPA alphabet, Byzantine musical symbols, and various other glyphs that the limited font support with pdfT_EX can not or only rudimentary provide.

L^AT_EX support for all engines is provided through the package garamondlibre by Bob Tennent. The package supports the usual options implemented by Bob; e.g., scaled lets you select a scaling factor, osf makes oldstyle numerals the default, etc.

With a price of £148, **almost anything** can be found FLOATING IN FIELDS.
— ¿But aren’t Kafka’s Schloß & Æsop’s Œuvres often *naïve* vis-à-vis the
dæmonic *phænix’s official rôle* in fluffy soufflés?

Garamond Libre offers Swash glyphs²: the nw shape gives you Swash upright and

¹<https://image.linotype.com/files/pdf/specimen.pdf>

²Not sure I would use them, at least not in upright shape — they do not seem to blend in well.

Family	Series	Shapes	Typeface Examples
<i>Garamond Libre</i>	Garamond Libre	(Encodings: T1, TS1, OT1, LY1, LGR, T2A, T2B, T2C, and TU)	
GaramondLibre-LF	m, b	n, it, (sl), sc, scit, (scsl)	Libre Garamond regular, <i>italic</i> , bold & <i>italic</i>
	m, b	nw, sw	Libre Garamond Swash upright and <i>Swash italics</i>

Supported figure styles for Garamond Libre are -LF, -OsF, -Sup, and -Inf.

Table 10.28: Classification of the Garamond Libre fonts

sw Swash italics; e.g., the next example is made by starting it with `\fontshape{nw}` `\selectfont`. Note that there is no `scnw`, so we get normal small caps.

With a price of £148, **almost anything** can be found **FLOATING IN FIELDS**.
 — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the
 dæmonic phoenix's official rôle in fluffy soufflés?

*Garamond Libre Swash
(shape nw) 10pt/12pt
(GaramondLibre-OsF)
Garamond Libre*

`\fontshape{sw}\selectfont` gets you Swash italics, but for short phrases or individual letters or words you can alternatively use `\textsw` to access them.

With a price of £148, **almost anything** can be found **FLOATING IN FIELDS**.
 — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the
 dæmonic phoenix's official rôle in fluffy soufflés?

*Garamond Libre Swash
(shape sw) 10pt/12pt
(GaramondLibre-OsF)
Garamond Libre*

If you know that you have an italic and upright Swash face (sw and nw) but no small caps Swash (scsw), consider adding the following rule to your document:

```
\DeclareFontShapeChangeRule{sw}{sc}{scsw}{nw}
```

This directs NFSS to switch to the upright Swash face if `scsw` is unavailable instead of switching to `sc`; see the discussion on page [→I 735](#). If we apply that, then the first line of the example text changes to

With a price of £148, **almost anything** can be found **Floating In Fields**. —

which is arguably better than getting straight small capitals without Swash.

10.4.7 URW Garamond No. 8

In the first quarter of the last century the Stempel Type Foundry released a Garamond adaption for hot-metal typesetting that has remained popular since. URW Garamond No. 8 is a freeware version based on this design and contributed by URW++ to the Ghostscript project under the AFP license. Because of this license, it is not automatically included in most T_EX distributions but can be easily installed using the `getnonfreefonts` script. The design has relatively short descenders, allowing it to be used with little leading.

Family	Series	Shapes	Typeface Examples
<hr/>			
URW Garamond No. 8 — no OpenType — (Encodings: T1 and TS1)			
ugm	m, b	n, it, (sl)	Roman, <i>italic</i> , bold , and <i>bold italics</i>
Garamondx GaramondNo8 (Encodings: T1, TS1, LY1, and TU)			
zgmj	m, b	n, it, (sl), sc, scit, (scsl)	Roman, <i>italic</i> , bold , and SMALL CAPS <i>ITALICS</i>
zgmj			ditto, but with 1234...9 oldstyle figures

URW Garamond No. 8 supports only lining figures in its original freeware release.
Garamondx supports lining and oldstyle figures (family name zgmj).

Table 10.29: Classification of the URW Garamond No. 8 font family

To use the font with pdf \TeX simply set `\rmdefault` to `ugm` or select that family explicitly, but note that the \LaTeX support files are offered only for the T1 encoding.

URW Garamond No. 8 10pt/12pt (ugm) — With a price of £148, **almost anything** can be found Floating In Fields.
— ¿But aren’t Kafka’s Schloß & Æsop’s Œuvres often *naïve* vis-à-vis the dæmonic phoenix’s official rôle in fluffy soufflés?

If you look closely, the fonts are missing some of the f-ligatures; e.g., you get “ff” instead of “fff”. These ligatures are missing in the Stempel Garamond as well, so their absence is not surprising. However, that and the missing small capitals limit the usefulness of the otherwise nice font.

So in 2006 Gaël Varoquaux produced an updated version of the fonts that included oldstyle figures, a first attempt at providing small capitals, a swash Q, and some kerning improvements.

Michael Sharpe used that version as a starting point for his reworking of URW Garamond No. 8 fonts, completely redoing the Small Caps shapes and making further improvements. \LaTeX support for his version is provided through the package `garamondx` and because of the AFP license of the original fonts also has to be manually installed using `getnonfreefonts`. Besides `scaled` and `osf`, the package supports special options such as `swashQ` to make the swash Q the default. Alternatively, you can get individual swash Qs with the command `\swashQ` that we use in the example below. A typesetting sample with matching mathematical fonts is shown in Figure 12.4 on page 264.

Table 10.30: Classification of the Gentium Plus font family

by Khaled Hosny to TrueType. In this format the family can, for example, be downloaded from <https://garamond.org/urw/> and set up using fontspec. The TrueType fonts also support small capitals, a full set of f-ligatures, and oldstyle figures.

10.4.8 Gentium Plus

Gentium is an award-winning design by Victor Gaultney with the aim to produce readable, high-quality publications. It supports a wide range of Latin- and Cyrillic-based alphabets as well as full support for polytonic and monotonic Greek.

ℒ_{TeX} support for the pdf_{TeX} is provided through the package `gentium` that makes the font the `\rmdefault` and also supports the option `scaled`.

Unicode engines

For Unicode engines you have to set up your own fontspec declaration.

With a price of £148, **almost anything** can be found FLOATING IN **FIELDS**. — ¿But aren’t Kafka’s Schloß & Æsop’s Œuvres often *naïve* vis-à-vis the dæmonic *phœnix’s official rôle* in fluffy soufflés?

Gentium Plus 10pt/12pt
(gentium) **Gentium Plus**

10.4.9 Kp (Johannes Kepler) Roman

Kp Roman is inspired by Palatino and has matching sans serif and monospaced designs and a full set of math fonts. When used with pdf_{TeX}, certain features, such as special ligatures or oldstyle numerals (shown below), can be activated by altering the family name as described on page 17; you can find the description of all three families and their NFSS classifications in Table 10.9 on page 18. If used with Unicode engines, the features can be activated through the typical feature sets as supported by fontspec. Examples with mathematics are shown in Figures 12.6 to 12.8 on pages 266–267.

With a price of £148, **almost anything** can be found FLOATING IN **FIELDS**. — ¿But aren’t Kafka’s Schloß & Æsop’s Œuvres often *naïve* vis-à-vis the dæmonic *phœnix’s official rôle* in fluffy soufflés?

qpl	m, b	n, it, (sl), sc, scit, (scsl)	Palatino regular, <i>italic</i> , bold , and Small Caps

Table 10.31: Classification of the Pagella (Palatino) family from the T_EX Gyre distribution

10.4.10 Palatino (T_EX Gyre Pagella)

Palatino, designed by Hermann Zapf (1918–2015), is one of the most widely used typefaces today [26]. You can feel the brush that created it, which gives it a lot of elegance. Although originally designed as a display typeface, due to its legibility, Palatino soon gained popularity as a text face as well.

T_EX Gyre Pagella shown here is based on the URW Palladio L version of the font family (which is set up with the T_EX Gyre `tgpagella` package). Typesetting samples with matching math fonts are shown in Figures 12.10 to 12.13 on pages 269–270.

With a price of £148, **almost anything** can be found FLOATING IN FIELDS. — ¿But aren’t Kafka’s Schloß & Æsop’s Œuvres often *naïve* vis-à-vis the dæmonic *phœnix’s official rôle* in fluffy soufflés?

10.5 Transitional/Neoclassical serif fonts

The Humanist and Garalde fonts discussed above are also often collectively referred to as Oldstyle fonts, and the Didone designs that we show in the next section are also known as Modern. In-between we have fonts classified as Transitional or Neoclassical that first appeared in the late 17th century.

There is no longer a calligraphic influence, and the letter axis is now nearly, if not completely, vertical. The weight difference between the thickest and thinnest points shows an even higher contrast compared to Garalde designs. The serifs are now (nearly) horizontal and less bracketed, and overall details become very refined. In this section we show roughly a dozen high-quality transitional designs, some of which are revivals of famous types of that period; others are new designs in the transitional style.

10.5.1 Antykwa Poltawskiego

The Antykwa Poltawskiego fonts (originally named “Antykwa Polska”) were designed in the 1920s by typographer Adam Półtawski with special shapes for frequent letters in the Polish language. For a long time it has been the major text type for musical publications in Poland.

Unicode engines

For Unicode engines you need to set up the font using `fontspec` declarations.

Family	Series	Shapes	Typeface Examples
<i>Antykwa Poltawskiego</i>	<i>Antykwa Poltawskiego</i>	(Encodings: T1, TS1, T5, OT1, OT4, LY1, and TU)	
antp	l, m, sb, b	n, it, (sl), sc, scit, (scsl)	Light, regular, semi-bold, bold , <i>italic</i> , and <small>SMALL CAPS ITALICS</small>
<i>Antykwa Poltawskiego Light</i>	<i>Antykwa Poltawskiego Light</i>	(Encodings: T1, TS1, T5, OT1, OT4, LY1, and TU)	
antpl	m, sb, b, eb	n, it, (sl), sc, scit, (scsl)	Regular, semi-bold, bold , extra-bold , <i>italic</i> , and <small>SMALL CAPS ITALICS</small>

The series specifications in *Antykwa Poltawskiego Light* are shifted by one weight with respect to *Antykwa Poltawskiego*; e.g., *m* in *Antykwa Poltawskiego* becomes *sb* in *Antykwa Poltawskiego Light*.

Table 10.32: Classification of the Antykwa Poltawskiego font family

ℒ_{TeX} support for pdf_{TeX} is provided through the package `antpol` by Janusz Marian Nowacki (1951–2020). The standard weight can be selected through the options `regular` (default) or `light`.

10.5.2 BaskervilleF and Libre Baskerville

Libre Baskerville is a revival of John Baskerville’s (1706–1775) typeface, designed by Pablo Impallari and Rodrigo Fuenzalida as a font family optimized for web usage. It is based on the American Type Founder’s Baskerville from 1941, but with a taller x-height, wider counters, and somewhat less contrast, making it work well for reading on computer screens. ℒ_{TeX} support for all engines is available with the `librebaskerville` package by Bob Tennent. There are matching math fonts by Michael Sharpe; see page 271.

- With a price of £148, **almost anything** can be found Floating In Fields.

— ¿But aren’t Kafka’s Schloß & Æsop’s Œuvres often *naïve* vis-à-vis the dæmonic *phoenix*’s official rôle in fluffy soufflés?
- Libre Baskerville* 9pt/12pt
(LibreBskvl-LF)
Libre Baskerville

The web optimization of Libre Baskerville means that it is less suited for traditional printing. For this reason Michael Sharpe created a variant version under the name BaskervilleF mostly by hollowing out the interiors of the Libre Baskerville

Family	Series	Shapes	Typeface Examples
<i>Libre Baskerville</i>	Libre Baskerville	(Encodings: T1, TS1, OT1, LY1, and TU)

(qbk) TeX Gyre Bonum

10.5.5 Cambria

Cambria is a commercial transitional serif typeface designed by Jelle Bosma with contributions from Steve Matteson and Robin Nicholas. It has even spacing and proportions, is intended to be used for body text, is especially suitable for small print, and displays well on low-resolution screens. This makes it, together with the fact that it offers extensive support for Latin, Greek, Cyrillic, Armenian, IPA symbols, and a full collection of math symbols, a very versatile solution for typesetting documents for consumption on screen as well as on paper.

Commissioned by Microsoft, it is shipped as part of the Windows operating system as well as in several Office products for different platforms. Thus, while the font requires a license for use, many users will have this license if they work on

Family	Series	Shapes	Typeface Examples
Cambria	Cambria	(Encodings: TU)	
—	m, b	n, it, (sl), sc, scit, (scsl)	Only for Unicode engines; see Example 10-5-1 below.

Supported figure styles are lining and oldstyle, selectable through fontspec’s Numbers key.

Table 10.36: Classification of the Cambria family

Windows or because they own a product that installs the font. Because of this and its excellent math capabilities, we decided to include it in the collection even though it is available only for Unicode engines and has the license restrictions.

Unicode engines

There is no support for pdfTeX, only for Unicode engines. Lining figures are the default figure style, but oldstyle figures are supported as well. Below we have selected them through the fontspec feature Numbers=OldStyle.

A larger example of the mathematical typesetting capabilities is shown in Figure 12.18 on page 274.

10-5-1

10.5.6 Bitstream Charter

Bitstream Charter is an original design by Matthew Carter based on the characters of Pierre-Simon Fournier, intended to work well on low-resolution devices; hence, it contains squared serifs and avoids excessive use of curves and diagonals. It is useful for many applications, including books and manuals. Charter was contributed by Bitstream to the X consortium.

Basic L^AT_EX support for the pdfTeX engine is provided through the package charter, but these days it is much better to use the package XCharter by Michael Sharpe as it offers improved small capitals, oldstyle, superior figures, and the typical options of a modern font package. Mathematical typesetting with matching fonts is shown in Figure 12.19 on page 275.

Unicode engines

For Unicode engines, a fontspec configuration is provided.

Table 10.38: Classification of the Charis SIL family

10.5.7 Charis SIL — A design based on Bitstream Charter

Charis SIL (developed by SIL International) is a transitional typeface that is closely based on the design of Bitstream Charter. However, its glyphs were completely redrawn with significant differences in serif structure, proportions, diacritics, and other characteristics, which can be easily seen if you compare the previous and the following sample. The font offers support for Latin and Cyrillic, and, if used with a Unicode engine, offers many additional glyphs including a full set of IPA symbols. \LaTeX integration is provided through the CharisSIL package by Bob Tennent.

The unusual si shape name selects Small Caps italics (normally this is called scit).

Table 10.40: Classification of the Literaturnaya font family

10.5.12 Literaturnaya — A favorite in the days of the USSR

Based on a design by Hermann Berthold from 1899, Literaturnaya was designed around 1940 by Anatolii Shchukin. Towards the end of the last century a digital version was developed by Lyubov Kuznetsova. The family was predominately used in the USSR and other socialist countries and was the standard Cyrillic typeface there in the period between 1950 and 1990. After the cold war it got more and more displaced by the then popular Times New Roman and is nowadays rarely seen.

TeX support files are provided by Vladimir Volovich. To make the font the default roman typeface, load his literat package (no options). The fonts are not part of the standard distributions but can be installed with getnonfreefonts.

Unicode engines

TrueType versions of the family are freely available on the Web, but they are not distributed through CTAN, so you have to install them yourself and then use fontspec if you want to use the family with a Unicode engine.

With a price of £148, **almost anything** can be found FLOATING IN FIELDS. — ¿But aren’t Kafka’s Schloß & Æsop’s Œuvres often naïve vis-à-vis the dæmonic *phœnix*’s official rôle in fluffy soufflés?

Literaturnaya 10pt/12pt
(tli) — no OpenType —

10.5.13 Lucida Bright

Lucida Bright is a modern design, but according to its designer Charles Bigelow, “[...] its inner forms are based on writing styles of the Italian Renaissance, and its sophisticated detailing is reminiscent of printing types of the French Enlightenment. It can be classified as a ‘Transitional’ or ‘Reale’ style of typeface, like the 18th century designs of Baskerville or Fournier”. They show, however, in my opinion aspects of Didone and even tend towards slap serif in parts — which just proves that classification in few categories is difficult.

The Lucida Bright fonts have matching sans and monospaced designs and a full set of math fonts. The families are described together in Section 10.2.10 on page 21, and the NFSS classification is given in Table 10.11 on page 22. They are the fonts we have used for this book, except that we have set them even smaller than the typeface

10.5.16 New Century Schoolbook (T_EX Gyre Schola)

The New Century Schoolbook typeface was designed at the beginning of the 20th century by Morris Fuller Benton (1872–1948) of the American Type Founders. It was created in response to a publisher’s commission that sought a typeface with maximum legibility for elementary schoolbooks. Italics were originally not part of the design; they were added in later revivals by Linotype and ITC.

T_EX Gyre Schola shown here is based on the URW Century Schoolbook L version of the font family (which is set up with the T_EX Gyre tgschola package).

Typesetting with matching mathematical fonts is available for all engines; see Figures 12.20 to 12.21 on page 276 for examples.

With a price of £148, **almost anything** can be found FLOATING IN

(Quattro-LF)
Quattrocento

10.5.20 Times Roman (T_EX Gyre Termes and Tempora)

Times Roman is Linotype's version of Monotype's Times New Roman, which was originally designed under the direction of Stanley Morison (1889–1967) for the *London Times* newspaper. The Adobe font that is built into many PostScript devices uses Linotype's 12-point design.

T_EX Gyre Termes shown here is based on the URW Roman No9 L version of the font family, which is set up with the T_EX Gyre tgtermes package.

Family	Series	Shapes	Typeface Examples
<i>Times Roman</i>	TeX Gyre Termes	(Encodings: T1, TS1, T5, OT1, LY1, and TU)	
qtm	m, b	n, it, (sl), sc, scit, (scsl)	Times Roman, <i>italic</i> , bold , and SMALL CAPS

Table 10.42: Classification of the Termes (Times) family from the T_EX Gyre distribution

Family	Series	Shapes	Typeface Examples
<i>Times Roman</i>	TeXGyreTermesX	(Encodings: T1, TS1, OT1, LY1, and TU)	
ntxlf	m, b	n, it, (sl), sc, scit, (scsl)	Times Roman, <i>italic</i> , bold , and SMALL CAPS with 12345
ntxosf	m, b	n, it, (sl), sc, scit, (scsl)	Times Roman, <i>italic</i> , bold , and SMALL CAPS with 12345

The family offers normal and larger Small Caps, but a selection can be made only through the newtxtext package, and not by changing the NFSS font family name.

Table 10.43: Classification of the Termes (Times) family from the New TX distribution

Times Roman 10pt/12pt
(qtm) TeX Gyre Termes

With a price of £148, **almost anything** can be found FLOATING IN **FIELDS**.
— ¿But aren’t Kafka’s Schloß & Æsop’s Œuvres often *naïve* vis-à-vis the
dæmonic *phænix’s official rôle* in fluffy soufflés?

Michael Sharpe developed a slight modification of the family under the name of TeXGyreTermesX that is used by his newtxtext package. It offers slightly enlarged small capitals (with the option `largesc`) and can set up oldstyle numerals (with the option `osf`). It also alters the positions of dots above *i* and *j* and makes other minor modifications.

Note that while it is possible to select oldstyle numbers by choosing the appropriate NFSS family name, the enlarged small capitals are available only when using the support package (which we did in the next sample behind the scenes).

Times Roman (with options largesc,osf) 10pt/12pt

10.5.22 STIX 2

The Scientific and Technical Information Exchange (STIX) Fonts project, sponsored by several leading scientific and technical publishers, intends to provide a comprehensive font set of mathematical symbols and alphabets under a royalty-free license for electronic and print publications. STIX 2, the current version, is an original design by Ross Mills, John Hudson, and Paul Hanslow of Tiro Typeworks, loosely based on Times New Roman but with a larger x-height.

Family	Series	Shapes	Typeface Examples
STIX 2	STIX Two Text	(Encodings: T1, TS1, OT1, and TU)	
SticksTooText-LF	m, b	n, it, (sl), sc, scit, (scsl)	STIX 2 regular, <i>italic</i> , bold , and SMALL CAPS

Supported figure styles for STIX 2 fonts are -LF, -OsF, -TLF, -T0sF, -Sup, and -Inf.

Table 10.46: Classification of the STIX 2 font family

ℒ_{TeX} support for the pdf_{TeX} engine is provided through the `stickstootext`¹ package by Michael Sharpe. It accepts the typical options such as `scaled` or `osf` but also others related to STIX’s math support; see the package documentation for details. Typesetting examples involving mathematics are shown in Figure 12.30 on page 282 (pdf_{TeX}) and Figure 12.31 on page 282 (Unicode engines).

Unicode engines

The STIX fonts also include text glyphs for Latin, Greek, and Cyrillic as well as IPA symbols, but these are available only with Unicode engines.

With a price of £148, **almost anything** can be found FLOATING IN **FIELDS**. — ¿But aren’t Kafka’s Schloß & Æsop’s Œuvres often *naïve* vis-à-vis the dæmonic *phoenix’s official rôle* in fluffy soufflés?

10.5.23 Utopia (Heuristica, Erewhon, and Linguistics Pro)

Utopia, designed by Robert Slimbach, combines the vertical stress and pronounced stroke contrast of 18th century Transitional types with contemporary innovations in shape and stroke details.

Andrey V. Panov extended the Utopia font family under the name Heuristica by adding additional accented glyphs, additional figure styles, and small capitals for the regular weight. The ℒ_{TeX} support for pdf_{TeX} is provided by Michael Sharpe through the package `heuristica` with options like `scaled`, `osf`, and others.

Unicode engines

For Unicode engines a `fontspec` specification file is provided.

Utopia 9.6pt/12pt
(Heuristica-T0sF)
Heuristica

With a price of £148, **almost anything** can be found FLOATING IN **Fields**. — ¿But aren’t Kafka’s Schloß & Æsop’s Œuvres often *naïve* vis-à-vis the dæmonic *phoenix’s official rôle* in fluffy soufflés?

Michael also extended the Heuristica family further by adding small capitals in all weights and real slanted shapes. He also changed the oldstyle design somewhat

¹This is indeed the package name: there is also a `stix2`, but that offers only very basic support.

Family	Series	Shapes	Typeface Examples
Heuristica	Heuristica	(Encodings: T1, TS1, T2A, T2B, T2C, LY1, and TU)	
Heuristica-TLF	m	n, it, (sl), sc	Heuristica regular, <i>italic</i> , and SMALL CAPS SHAPES
	b	n, it, (sl)	Heuristica bold and <i>bold italic</i> but no Small Caps
Erewhon	Erewhon	(Encodings: T1, TS1, T2A, T2B, T2C, LY1, and TU)	
erewhon-LF	m, b	n, it, sl, sc	Erewhon regular, <i>italic</i> , <i>slanted</i> , bold , and SMALL CAPS
Linguistics Pro	Linguistics Pro	(Encodings: T1, TS1, T2A, T2B, T2C, T3, TS3, OT1, LGR, LY1, and TU)	
LinguisticsPro-LF	m, b	n, it, (sl), sc	Linguistics Pro in <i>italic</i> , bold , and SMALL CAPS

Supported figure styles for Heuristica are TLF, -T0sF, -Sup, and -Inf.
Supported figure styles for Erewhon are LF, -0sF, -TLF, -T0sF, -Sup, and -Inf.
Linguistics Pro is available only in -LF and -0sF.

Table 10.47: Classification of the Utopia family and its forks

and scaled down the fonts by 6% to match the original Utopia font sizes. His version is named Erewhon, and the support package is erewhon. Compare it to the previous example.

With a price of £148, **almost anything** can be found FLOATING IN
FIELDS. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis
the dæmonic *phoenix's official rôle* in fluffy soufflés?

Utopia 10pt/12pt
(erewhon-T0sF) erewhon

A different extension of the original Utopia is Linguistics Pro by Stefan Peev. It is of special interest if you need to combine Latin, polytonic Greek, and/or Cyrillic, as it offers modern Bulgarian letterforms and with Unicode engines also traditional forms for the Russian language (available through the OpenType Stylistic Set 01). Otherwise they are more or less identical to Heuristica with a slightly wider running length. It also offers IPA symbols.

L^AT_EX support for all engines is provided by Bob Tennent through the package linguisticspro, which accepts the option scaled.

With a price of £148, **almost anything** can be found FLOATING IN
Fields. – ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis
the dæmonic *phoenix's official rôle* in fluffy soufflés?

Linguistics Pro 9.6pt/12pt
(LinguisticsPro-0sF)
LinguisticsPro

Michael Sharpe prepared matching math fonts that work well with all of the Utopia variants; see Figure 12.32 on page 283 for an example page. There is also the Fourier-GUTenberg bundle by Michel Bovani, which too is based on Adobe Utopia and offers full support for math, especially in the French style. For text, the fonts have a glyph coverage similar to Heuristica, which is why they are not covered here, but only briefly in Chapter 12 on math fonts.

10.6 Didone (Modern) serif fonts

Fonts classified as Didone or Modern (with Modern referring to a period starting in the second half of the 18th century) take the Transitional design ideas even further and introduce new aspects. The name is coined from the surnames of two very famous type designers of the period: Firmin Didot (1764–1836) and Giambattista Bodoni (1740–1813).

Stroke contrast now becomes even more pronounced, with heavy parts getting even heavier and light strokes being reduced to hairlines. The weight axis is now completely vertical. The counters (the partially enclosed, somewhat rounded space in characters such as a, c, e, f, s, etc.) often become very tight. Serifs are very abrupt, narrow, and unbracketed with a nearly constant stroke width. While we have seen in Transitional fonts that some character terminals start looking more like droplets, Didone fonts often show pronounced ball terminals, either full circles or heavier teardrops.

Below we show a handful of high-quality Didone designs that have been set up for use with pdf \TeX and can be used as alternatives to \LaTeX 's bread and butter family Computer Modern (which too is a Didone design). Most have equally good coverage in terms of different shapes (compared to CM) but often offer more weights — in the case of the Noto families this amounts to a truly impressive number of possible alternatives.

10.6.1 Computer Modern Roman / Latin Modern Roman

Donald Knuth's Computer Modern, the first fonts available for \TeX , are classical Didone designs, and so are the derived Latin Modern fonts. Together with their matching sans serif and monospaced companions and the matching math fonts, they enable you to typeset any kind of document using a single consistent “design”. For many years these have been the fonts that most people had to use and even nowadays usually still use (after all, they work out of the box) — so much that seeing COMPUTER MODERN TYPEFACES became a synonym for “was produced with \LaTeX ” and vice versa.¹ You can find the description of these families in Section 9.5.1 and their NFSS classifications in Tables 9.5 and 9.6.

Latin Modern Roman

10pt/12pt (l μ r)

Latin Modern Roman

With a price of £148, **almost anything** can be found FLOATING IN **Fields**. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often naïve vis-à-vis the dæmonic *phænix's official rôle* in fluffy soufflés?

Unicode engines

For Unicode engines only there is also the New Computer Modern OpenType family of fonts by Antonis Tsolomitis. Its aim is to augment Computer Modern and enable typesetting in many more scripts and languages. See Figure 12.36 on page 286 for an example of its math typesetting quality.

¹I hope that this chapter proves that this is an unwarranted prejudice and that we are long past the stage that using \LaTeX means “you can use any font you like as long as it is called Computer Modern”.

Family	Series	Shapes	Typeface Examples

<i>Supported figure styles for Libre Bodoni are -TLF, -Sup, and -Inf.</i>			

Table 10.49: Classification of the Libre Bodoni font family

10.6.2 GFS Bodoni

GFS Bodoni was designed by Takis Katsoulidis based on the work of the famous 18th century Italian type cutter Giambattista Bodoni (1740–1813). \LaTeX support is provided through the package `gfsbodoni`, which defines the command `\textbodoni` to access the font selectively. If loaded with the option `default`, GFS Bodoni is also made the roman default font. Besides Latin languages, the family fully supports polytonic Greek.

With a price of £148, **almost anything** can be found **Floating In Fields**. — ¿But aren’t Kafka’s Schloß & Æsop’s Œuvres often *naïve* vis-à-vis the dæmonic *phænix*’s *official rôle* in fluffy soufflés?

GFS Bodoni 10pt/12pt
(`bodoni`) **GFS Bodoni**

10.6.3 Libre Bodoni

Designed by Pablo Impallari and Rodrigo Fuenzalida, the Libre Bodoni fonts are based on the 19th century Morris Fuller Benton (1872–1948)’s Bodoni ATF design. Note that this family appears to be already quite dark in its medium weight. \LaTeX support for all engines is available with the `LibreBodoni` package by Bob Tennent.

With a price of £148, **almost anything** can be found **Floating In Fields**. — ¿But aren’t Kafka’s Schloß & Æsop’s Œuvres often *naïve* vis-à-vis the dæmonic *phænix*’s *official rôle* in fluffy soufflés?

Libre Bodoni 10pt/12pt
(`LibreBodoni-TLF`)
Libre Bodoni

Not that there is anything wrong with Computer or Latin Modern, but as you can see, there are many beautiful designs out there, and they are usually just a package load away.

Supported figure styles for Theano Didot are -TLF and -T0sF.

Table 10.51: Classification of the Theano Didot font family

10.6.4 GFS Didot

In 1805 the famous French type cutter Firmin Didot (1764–1836) designed a new Greek typeface influenced by the neoclassical ideals of that time that, after arriving in Greece, became widely popular and was used for all kinds of publications until the last decades of the 20th century.

GFS Didot is a new design from 1994 by Takis Katsoulidis based on Didot’s original work. Unfortunately the Latin alphabet added into the font cannot be recommended because it contains very inconsistently designed characters, and the fact that it is partly inspired by Hermann Zapf’s (1918–2015) Palatino does not help. It also means that it is no longer a pure Didone design but shows a mixture of oldstyle and modern aspects. Thus, while the font provides a valuable polytonic Greek alphabet, you should match it with a different font for typesetting in Latin; i.e., do not use the gfsdidot support package because that makes the Latin font the default. A much better alternative for classical texts is Theano Didot described in the next section.

GFS Didot 10pt/12pt
(udidot) GFS Didot

With a price of £148, **almost anything** can be found FLOATING IN **Fields**. — ¿But aren’t Kafka’s Schloß & Æsop’s Œuvres often naïve vis-à-vis the dæmonic *phœnix*’s *official rôle* in fluffly soufflés?

10.6.5 Theano Didot

The Theano Didot font is one of several fonts designed by Alexey Kryukov from historic samples, in this case, the work of Firmin Didot (1764–1836). Originally meant to be polytonic Greek-only typefaces, Alexey supplemented them with stylistically matching Latin letters (and some of his fonts, though not Theano Didot, also with

Family	Series	Shapes	Typeface Examples
Old Standard	Old Standard	(Encodings: T1, TS1, T2A, T2B, T2C, OT1, LGR,, LY1, and TU)

(TheanoDidot-T0sF)
Theano Didot

10.6.6 Noto Serif

The Noto Serif fonts (an extended version of Droid Serif with well-designed small capitals) have matching sans and monospaced designs. The families are described together on page 26, and the NFSS classification is given in Table 10.14 on page 28. A sample page with matching math fonts is shown in Figure 12.38 on page 287.

With a price of £148, **almost anything** can be found **FLOATING IN FIELDS**. — ¿But aren’t Kafka’s Schloß & Æsop’s Œuvres often **naïve** vis-à-vis the dæmonic **phoenix’s official rôle** in fluffy soufflés?

Noto Serif 10pt/12pt
(NotoSerif-0sF)
Noto Serif

10.6.7 Old Standard

Designed by Alexey Kryukov, Old Standard (revised in 2019 by Robert Alessi) reproduces the printing style of the early 20th century, reviving a specific type of Modern (classicist) style of serif typefaces. The glyph set provided by the font supports type-setting of Old and Middle English, Old Icelandic, Cyrillic (with historical characters, extensions for Old Slavonic and localized forms), Gothic transliterations, critical editions of Classical Greek, Latin, etc.

Unicode engines

However, some of the glyph variants are available only if a Unicode engine is used, because of limitations in the number of glyph slots in Type 1 fonts.

Family	Series	Shapes	Typeface Examples

10.7 Slab serif (Egyptian) fonts

Slab serif fonts got introduced in the 19th century, and perhaps because anything Egyptian was quite popular after Napoleon’s expedition of Egypt, they were popularized as Egyptian Hieroglyph Slab Serif and are these days still sometimes referred to as Egyptian fonts even though there is no real relationship to this country whatsoever.

Family	Series	Shapes	Typeface Examples
<i>Bitter</i>	Bitter	(Encodings: T1, TS1, OT1, LY1, and TU)	
Bttr-TLF	m	n, it, (sl)	Regular and <i>italic shapes</i>
	b	n	Bold has no italics

Table 10.54: Classification of the Bitter font family

Slab serif fonts form a large and varied genre. What they have in common is a fairly heavy weight (especially in fonts for display usage), low contrast between thick and thin strokes, and very prominent unbracketed serifs. Otherwise, many different design concepts are employed by different families. There are geometric designs with minimal stroke differences (like a sans serif font with added serifs), while others are very similar to traditional serif designs but with more prominent serifs.

Slab serif designs intended especially for display usage are usually very bold with exaggerated serifs to get the reader’s attention in posters, etc., by “shouting out loud”. Fonts oriented towards use at body text size or smaller usually show less extreme characteristics and often use only slab serifs to increase legibility but are otherwise close to conventional book type fonts. This is certainly true for the families shown below that are all intended for continuous text.

You can find further slab serif designs in Section 10.9 on monospaced fonts. However, the fonts there are less suited for use in continuous text because all the characters show the same width. They have therefore got their own section.

10.7.1 Bitter

Designed by Sol Matas, Bitter is a contemporary slab serif typeface for text, specially for comfortably reading on computer displays. It has a large x-height and little variation in stroke width and is somewhat darker than the regular weight of most other fonts. L^AT_EX support for all engines is available through the bitter package by Bob Tennent, which supports the option `scaled` for specifying a scale factor.

With a price of £148, **almost anything** can be found **Floating In Fields**. — ¿But aren’t Kafka’s Schloß & Æsop’s Œuvres often *naïve* vis-à-vis the dæmonic *phœnix’s* official rôle in fluffy soufflés?

Bitter 10pt/13pt
(Bttr-TLF) **Bitter**

10.7.2 Concrete Roman

For the text of his book *Concrete Mathematics* [58], Donald Knuth designed a new typeface [94] to go with the Euler mathematics fonts designed by Hermann Zapf (1918–2015) [202]. This font family, called Concrete Roman, was created from the Computer Modern METAFONT sources by supplying different parameter settings.

Family	Series	Shapes	Typeface Examples
<i>Concrete Roman</i> CMU Concrete (Encodings: T1, TS1, OT1, and TU)			
ccr	m	n, it, sl, sc	Concrete Roman medium in <i>italic</i> , <i>slanted</i> , and SMALL CAPS shapes
	c	sl	<i>Concrete Roman condensed slanted (only OT1 and 9pt font size)</i>
	b	n, it	— Not available with pdfTeX, only in Unicode engines —

Table 10.55: Classification of the Concrete font family

L^AT_EX support for the pdfT_EX engine is provided through the package `ccfonts` by Walter Schmidt (1960–2021). The package takes care of small but important typographical details, such as increasing the value of `\baselineskip` slightly because of the darker color of the font. The feature provided by the `exscale` package is available as the package option `exscale`; see Section 9.5.7 on page 704 for details. The `exscale` package itself cannot be used because it is set up to work with only Computer Modern math fonts.

Example pages of mathematical typesetting are shown in Figure 12.39 on page 288 (with Concrete Math) and in Figure 12.40 on page 289 (with Euler fonts).

Note that the font has no bold weight. Instead, the L^AT_EX support file uses Computer Modern bold by default as a substitute, which does not work very well if the fonts are mixed (though it gets emphasized due to the color change).

Concrete Roman 10pt/13pt
(ccr) **CMU Concrete**

With a price of £148, **almost anything** can be found **FLOATING**
In Fields. — ¿But aren’t Kafka’s Schloß & Æsop’s Œuvres often naïve
vis-à-vis the dæmonic *phoenix’s official rôle* in fluffy soufflés?

As an alternative for the missing bold typeface, the `ccfonts` package offers the option `boldsans` to use the semi-bold series of the Computer Modern Sans fonts as a replacement. This means that if used without any further adjustments, headings in standard classes are then typeset using this font series, which actually looks quite nice.

Unicode engines

OpenType fonts of the family for use in Unicode engines do exist. They offer additional characters and also true **bold** and **bold italic** shapes.

The condensed cut is of very limited use because it exists only as a slanted shape in OT1 encoding and 9pt font size. It was produced just for typesetting the marginal comments in Don’s book and was never meant for general use. Still, if you have a similar use case, it might be handy. Below we deliberately asked for condensed slanted at 12pt: watch what happens:

*Concrete Roman condensed
slanted 12pt/14pt*
(ccr) — only OT1 —

With a price of £148, **almost anything** can be found **Floating In**
Fields. — ¿But aren’t Kafka’s Schloß & Æsop’s Œuvres often naïve vis-à-vis the
dæmonic *phoenix’s official rôle* in fluffy soufflés?

10.7.3 DejaVu Serif

DejaVu Serif exists in a regular and a condensed cut and has a matching sans serif and monospaced design. You can find the description of all three families on page 12 and their NFSS classifications in Table 10.4 on page 13.

Unicode engines

For Unicode engines there are matching math fonts, shown in Figure 12.41 on page 289.

With a price of £148, **almost anything** can be found **Floating In Fields**. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phœnix's official rôle* in fluffy soufflés?

(SourceSerifPro-OsF)
Source Serif Pro

10.8 Sans serif fonts

In contrast to the serif font families, we present all sans serif font families in alphabetical order by name. There are, of course, also classification schemes for sans serif fonts, but the distinctions are much hazier and are less useful when trying to find suitable fonts.

Many books on typography discuss how to select a suitable sans serif font to a given serif one, but it depends so much on how the two are used together that we give only a few general rule of thumbs here.

If the sans font is used as part of the body text and is intermixed with the serif font within sentences (as in this book, where we use sans serif for denoting package names, etc.), then it is best if both families have the same flow, i.e., a similar width of individual characters and consequentially a similar running length. In most cases they should also have similar characteristics in x-height, capital height, slope of their italics, etc., so that they blend well with each other.

If you are typesetting using one of the few larger “meta”-families such as Latin Modern or IBM Plex, then this is automatically the case when selecting the corresponding sans serif font from the family.

For many fonts shown in the previous sections, you have to decide on a companion sans serif by yourself — by setting up some typical sample text and studying the results. Sometimes one or the other family needs scaling up or down to achieve a similar x-height; this is why most font packages offer you a `scaled` or `scale` option. For example, here we combine Palatino (T_EX Gyre Pagella) with Quattrocento Sans scaled down to 96% to get matching x-heights.

<p>The dazed brown fox quickly gave 123456789 jumps while counting back- wards from 9 to 1. <i>Then he repeated</i> <i>the exercise!</i></p>	<pre>\usepackage{tgpagella} \usepackage[sf,scaled=.96]{quattrocento} The \textsf{dazed brown} fox quickly gave 123456789 jumps while \textsf{counting backwards} from 9 to 1. \emph{Then he \textsf{repeated} the exercise}!</pre>
--	---

10-8-1

Below we show samples of roughly thirty sans serif designs. A few of them are suitable only for display, but many can be successfully used as the main document font or as a companion to a serif family, depending on your use case. Typically the support packages offer options to set the fonts up either way.

10.8.1 Alegreya Sans

The Alegreya Sans family has a matching serif design (but no monospaced variant). You can find the description of both families on page 11 and the NFSS classification in Table 10.2 on the same page.

Alegreya Sans 10pt/12pt
(AlegreyaSans-Of)

;But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic
phœnix's official rôle in fluffy soufflés?

10.8.2 Arimo

The Arimo family, designed by Steve Matteson, is a sans serif font that is metrically compatible with Arial. It contains the glyphs necessary for typesetting in many languages including Greek and Cyrillic. However, the non-Latin glyphs are accessible

Family	Series	Shapes	Typeface Examples
<i>Arimo</i>	Arimo	(Encodings: T1, TS1, OT1, LY1, and TU)

qag	m	n, (it), sl, sc, (scit), scsl	Avant Garde regular, <i>oblique</i> , bold , and <i>SMALL CAPS</i>

Table 10.57: Classification of the Adventor (Avant Garde) family from the T_EX Gyre distribution

only in Unicode engines at the moment as the support files for pdfT_EX cover only Latin languages. Basic L^AT_EX support for all engines is provided through the package `arimo` by Bob Tennent, which sets up Arimo as `\sfdefault` and offers the usual options such as `scaled` or `sfdefault`.

With a price of £148, **almost anything** can be found [Floating In Fields](#). — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phœnix's official rôle* in fluffy soufflés?

Arimo 10pt/12pt
(Arimo-TLF) **Arimo**

10.8.3 ITC Avant Garde Gothic (T_EX Gyre Adventor)

Avant Garde Gothic was designed by Herb Lubalin and Tom Carnase based on the distinctive logo designed for *Avant Garde* magazine. It is a geometric sans serif type with basic shapes built from circles and lines. It is effective for headlines and short texts, but it needs generous leading. A (commercially available) condensed version that better retains legibility in lengthier texts was designed by Ed Benguiat. The T_EX Gyre Adventor version shown here is based on the URW Gothic L version of the font family.

With a price of £148, **almost anything** can be found [FLOATING IN FIELDS](#). — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phœnix's official rôle* in fluffy soufflés?

ITC Avant Garde Gothic 9pt/13pt
(qag) **TeX Gyre Adventor**

The font family can be set up as the document sans serif font with the help of the T_EX Gyre `tgadventor` package. Like all other T_EX Gyre support packages it provides the options `scale`, `matchlowercase`, and `matchuppercase`, to allow matching font family to other fonts used in the document.

Family	Series	Shapes	Typeface Examples
<i>Cabin</i>	Cabin, CabinCondensed	(Encodings: T1, TS1, OT1, LY1, and TU)

Supported figure styles for Cabin are -TLF and -Sup.

Table 10.58: Classification of the Cabin font family

10.8.4 Cabin

Cabin is a humanist sans serif family designed by Pablo Impallari. It offers four weights with italics and true small capitals. A compatible condensed family is also available. According to the designer, it was inspired by typefaces from Eric Gill (1882–1940) and Edward Johnston, with a touch of modernism.

L^AT_EX support for all engines is available through the package `cabin` by Bob Tennent providing the typical options such as `condensed`, `sfdefault`, `medium`, and others.

Cabin 10pt/12pt

10.8.5 Chivo

Chivo (Spanish for goat) is a Grotesque sans serif font family designed by Héctor Gatti. It offers upright and italic shapes in seven weights from thin (extra-light) to black (ultra-bold). The light and regular weights are usable for body texts, while the bold and black weights are meant for headlines. L^AT_EX support for all engines is provided through the package `Chivo` by Arash Esbati. With the options `thin`, `light`, or `medium` you can change the default sans serif body font, and with `extrabold` or `black` you can request that the black weight be used instead of bold.

10.8.6 Classico — A design based on Optima

Optima, designed by Hermann Zapf (1918–2015) in 1958, is a font family I personally like very much. It is very calligraphic in nature with varying stroke width in the letters and works well as a display face but equally well in body text size for whole documents. It is a bit like an Oldstyle serif design with only implied serifs. In 1998 Zapf in collaboration with KOBAYASHI Akira reworked its design, which was released under the name Optima Nova. As with many fonts by Hermann Zapf (1918–2015) Optima has many admirers and as a result unfortunately many pirate copies (usually of inferior quality) under different names.

If you are using a Macintosh, then Optima (but not Optima Nova) is one of the system fonts, which is lovely as it allows you to use this superb family in a Unicode T_EX engine directly using its TrueType name `Optima`. But this does not work on other operating systems or for pdfT_EX.

Fortunately, there is also the family URW Classico, which is a rework of the original Optima by its designer for the URW foundry. This family is freely usable (though you have to install it yourself via `getnonfreefonts` due to its license restrictions).

L^AT_EX support for all engines is provided through the package `classico` by Bob Tennent providing the options `scaled` to specify a scale factor and `sfdefault` (which I often use) to make this family the default document family. Being a sans serif design the italics are more oblique than true italics, and the small capitals are faked — however, they do not come out too badly because the characters have a varied stroke width.

With a price of £148, **almost anything** can be found **FLOATING IN FIELDS**. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often **naïve** vis-à-vis the dæmonic phoenix's official rôle in fluffy soufflés?

	el, l	n	Clear Sans Light and extra-light (only upright)

Supported figure styles for Clear Sans are -LF and -TLF.

Table 10.61: Classification of the Clear Sans family

10.8.7 Clear Sans

Clear Sans is a design by Daniel Ratighan at Monotype. It was commissioned by Intel, and it is particularly suitable for user interfaces, because it has slightly narrow proportions and unambiguous glyphs; e.g., “I” (uppercase i) has serifs to distinguish it from “l” (lowercase l). Clear Sans is available in three weights with corresponding italics (regular, medium, and bold), plus thin and light upright (without italics).

Basic L^AT_EX support for all engines is provided through the package ClearSans by Bob Tennent, which sets up Clear Sans as `\sfdefault` and offers the usual options such as `scaled`, `sfdefault`, or `medium`. The light and thin weights are made available through `\textsf{sl}` and `\textsf{st}`, respectively.

Clear Sans 10pt/12pt

With a price of £148, **almost anything** can be found [Floating In Fields](#). — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phœnix's official rôle* in fluffy soufflés?

CM Bright 10pt/12pt (cmbr)
— no OpenType —

10.8.9 Cuprum

Cuprum, designed by Ivan Gladkikh (a.k.a. Jovanny Lemonad), is a narrow grotesque sans serif typeface inspired by the works of Miles Newlyn. It is offered in two weights and upright and italic shapes. L^AT_EX support for pdfT_EX is provided through the package `cuprum` by Federico Roncaglia. Somewhat unconventionally, the missing Small Caps shape is aliased to boldface when pdfT_EX is used.

Unicode engines

For Unicode engines you have to set up the font using `fontspec`.

With a price of £148, **almost anything** can be found [Floating In Fields](#). — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phœnix's official rôle* in fluffy soufflés?

Cuprum 10pt/12pt
(cpr) Cuprum

10.8.10 Cyklop

The Cyklop typeface was designed roughly a hundred years ago in a workshop at a type foundry in Warsaw. This sans serif typeface has a highly modulated stroke with vertical stems that are much heavier than horizontal ones. Most characters have thin rectangles as additional counters, which give the unique shape of the characters. The font is available in only one weight — a request for the medium series gives you the same as `\bfseries`.

L^AT_EX support for pdfT_EX is provided through the package `cyklop` by Janusz Marian Nowacki (1951–2020), but that just sets `\rmdefault`, which is not very helpful unless you really want the whole document in this typeface. As the font is mainly of interest for headings and other display material and not for body text, it is probably best to set it up manually as needed.

A Cyklop Heading

Cyklop 17pt/20pt
(cyklop) Cyklop

Family	Series	Shapes	Typeface Examples
Cyklop	Cyklop	(Encodings: T1, TS1, T5, OT1, OT4, LY1, and TU)

10.8.11 DeJaVu Sans

DeJaVu Sans has a matching slab serif and a monospaced design. You can find the description of all three families on page 12 and their NFSS classifications in Table 10.4 on page 13.

<i>DejaVu Sans 9pt/12.5pt</i> (DejaVuSans-TLF) DejaVu Sans	With a price of £148, almost anything can be found Floating In Fields . — ħBut aren’t Kafka’s Schloß & Æsop’s Œuvres often <i>naïve</i> vis-à-vis the dæmonic <i>phænix’s official rôle</i> in fluffy soufflés?
<i>DejaVu Sans Condensed 9pt/12.5pt</i> (DejaVuSansCondensed-TLF) DejaVu Sans Condensed	With a price of £148, almost anything can be found Floating In Fields . — ħBut aren’t Kafka’s Schloß & Æsop’s Œuvres often <i>naïve</i> vis-à-vis the dæmonic <i>phænix’s official rôle</i> in fluffy soufflés?

10.8.12 Fira Sans

Erik Spiekermann’s Fira Sans has a matching monospaced design. This Humanist Sans works great as a body text font with many different weights and also offers polytonic Greek if that is needed. Both families are described on page 14, and their NFSS classifications can be found in Table 10.5.

Unicode engines

Xiangdong Zeng provided matching math fonts; see Figure 12.43 on page 291.

<i>Fira Sans 10pt/13pt</i> (FiraSans-OsF) Fira Sans	With a price of £148, almost anything can be found FLOATING IN FIELDS . — ħBut aren’t Kafka’s Schloß & Æsop’s Œuvres often <i>naïve</i> vis-à-vis the dæmonic <i>phænix’s official rôle</i> in fluffy soufflés?
--	--

10.8.13 Gandhi Sans

The Gandhi Sans fonts have a matching serif family described on page 15. The NFSS classifications are found in Table 10.6.

<i>Gandhi Sans 10pt/12pt</i> (GandhiSans-OsF) Gandhi Sans	With a price of £148, almost anything can be found FLOATING IN FIELDS . — ħBut aren’t Kafka’s Schloß & Æsop’s Œuvres often <i>naïve</i> vis-à-vis the dæmonic <i>phænix’s official rôle</i> in fluffy soufflés?

Family	Series	Shapes	Typeface Examples
<i>GFS Neo-Hellenic</i>	GFS Neo-Hellenic	(Encodings: T1, OT1, LGR, and TU)	
neohellenic	m, b	n, it, sl, sc, sco	Regular, bold , <i>italic</i> , <i>oblique</i> , and <i>SMALL CAPS OBLIQUE</i>

The supported figure style for GFS Neo-Hellenic is -TLF.

Unfortunately, `sco` is a nonstandard shape name for `scsl`; thus, low-level shape commands are needed to access it.

Table 10.64: Classification of the GFS Neo-Hellenic font family

10.8.14 GFS Neo-Hellenic

In 1927 a Greek type called New Hellenic designed by Victor Scholderer (1880–1971) was cut by Lanston Monotype in Britain. GFS Neo-Hellenic is a digitalization based on this design. It offers both true italics and an oblique shape, although the differences are not easy to spot.

LaTeX support is provided through the package `gfsneohellenic` that defines the command `\textneohellenic` to access the font selectively. If loaded with the option `default`, GFS Neo-Hellenic is also made the roman default font. The family is well matched to mathematical fonts from CM Bright, which makes this an option when typesetting with pdfTeX. Besides Latin languages, it fully supports polytonic Greek.

With a price of £148, **almost anything** can be found **FLOATING** **In Fields**. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phœnix's official rôle* in fluffy soufflés?

GFS Neo-Hellenic 10pt/12pt
(neohellenic)
GFS Neohellenic

Unicode engines

In 2018, GFS Neohellenic Math, a matching math font, was commissioned. This font exists only in OpenType format and thus can be used only with Unicode engines. It is made available through the package `gfsneohellenicot`. As a high-quality solution for sans serif text and math, this makes the package very attractive for situations such as presentations; see Figure 12.44 on page 291.

10.8.15 Gillius

The Gillius family of fonts designed by Hirwen Harendal was inspired by Eric Gill's (1882–1940) famous Gill Sans. It is available in medium and condensed width in all faces. LaTeX support for all engines is provided through the packages `gillius` and `gillius2` by Bob Tennent. The option `condensed` lets you use the condensed faces for the whole document.

With a price of £148, **almost anything** can be found **Floating In Fields**. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phœnix's official rôle* in fluffy soufflés?

Gillius 10pt/12pt
(GilliusADF-LF)
Gillius ADF

Family	Series	Shapes	Typeface Examples
<i>Gillius ADF</i>	Gillius ADF	(Encodings: T1, TS1, OT1, LY1, and TU)

Gillius ADF No2 Cond

With a price of £148, **almost anything** can be found **Floating In Fields**. — ¿But aren’t Kafka’s Schloß & Æsop’s Œuvres often *naïve* vis-à-vis the dæmonic *phoenix’s official rôle* in fluffy soufflés?

10.8.16 Helvetica (T_EX Gyre Heros)

Helvetica was originally designed by Max Miedinger (1910–1980) for the Haas foundry of Switzerland, hence the name. It was later extended by the Stempel foundry, with further refinements being made by Mergenthaler Linotype in the United States. Helvetica is purported to be one of the most popular typefaces of all time.

T_EX Gyre Heros shown here is based on the URW Nimbus Sans L version of the font family (which is set up with the T_EX Gyre tgheros package):

Helvetica 10pt/13pt
(qhv) TeX Gyre Heros

With a price of £148, **almost anything** can be found **FLOATING IN FIELDS**. — ¿But aren’t Kafka’s Schloß & Æsop’s Œuvres often *naïve* vis-à-vis the dæmonic *phoenix’s official rôle* in fluffy soufflés?

Family	Series	Shapes	Typeface Examples
<i>Helvetica</i>		TeX Gyre Heros (Encodings: T1, TS1, T5, OT1, LY1, and TU)	
qhv	m, c, b, bc	n, (it), sl, sc, (scit), scsl	Helvetica regular, <i>oblique</i> , bold , and SMALL CAPS
<i>Helvetica Condensed</i>		TeX Gyre Heros Cn (Encodings: T1, TS1, T5, OT1, LY1, and TU)	
qhvc	m, x, b, bx	n, (it), sl, sc, (scit), scsl	Helvetica Narrow regular, <i>oblique</i> , bold , and SMALL CAPS

Table 10.66: Classification of the Heros (Helvetica) family from the T_EX Gyre distribution

The T_EX Gyre Heros Condensed family implements a narrow version of Helvetica. It can be selected through the package option `condensed` or directly via the NFSS family name.

With a price of £148, **almost anything** can be found FLOATING IN **FIELDS**. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phœnix's official rôle* in fluffy soufflés?

Helvetica Condensed

TeX Gyre Heros Cn

10.8.17 Inria Sans

The Inria Sans family has a matching serif design. You can find the description of both families on page 16 and their NFSS classifications in Table 10.8 on page 17.

With a price of £148, **almost anything** can be found Floating In Fields. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phœnix's official rôle* in fluffy soufflés?

Inria Sans 10pt/12pt
(InriaSans-OsF)
Inria Sans

10.8.18 Iwona

Iwona was designed by Małgorzata Budyta for typesetting newspapers and similar periodicals as an alternative version of her Kurier fonts shown below. The difference lies in the absence of ink traps, which typify the Kurier family, e.g., “any” (Kurier) vs. “any” (Iwona). As a result, Iwona runs noticeably shorter even though it has a similar design. The family is offered in five weights and two widths and supports an extended character set including Latin and Cyrillic.

L^AT_EX support for pdfT_EX is provided through the package `iwona` by Janusz Marian Nowacki (1951–2020). The default weight can be changed through `light`, and with `condensed` you can reduce the width. Note that the package installs the family as the document body font, i.e., as `\rmdefault`!

Matching math fonts are available too and can be activated with the option `math`. They cover the basic symbols but not those from `amssymb`, which would keep their shapes if used; see sample pages in Figures 12.45 to 12.46 on page 292.

Family	Series	Shapes	Typeface Examples
<i>Iwona</i>	Iwona	(Encodings: T1, TS1, T2A, T2B, T2C, OT1, OT2, OT4, LY1, and TU)	
iwona	l, m, sb, b, eb lc, c, sbc, bc, ebc	n, it, sc, scit	Regular, bold , <i>italic</i> , and <i>SMALL CAPS ITALICS</i> ... and condensed, bold , <i>italic</i> , and <i>SMALL CAPS ITALICS</i>
<i>Iwona Light</i>	Iwona Light	(Encodings: T1, TS1, T2A, T2B, T2C, OT1, OT2, OT4, LY1, and TU)	
iwonal	m, sb, b, eb, ub c, sbc, bc, ebc, ubc	n, it, sc, scit	Light regular, bold , <i>italic</i> , and <i>SMALL CAPS ITALICS</i> ... and light condensed, bold , <i>italic</i> , and <i>SMALL CAPS ITALICS</i>
<i>Iwona Condensed</i>	Iwona Cond	(Encodings: T1, TS1, T2A, T2B, T2C, OT1, OT2, OT4, LY1, and TU)	
iwonac	l, m, sb, b, eb lx, mx, sbx, bx, ebx	n, it, sc, scit	Condensed regular, bold , <i>italic</i> , and <i>SMALL CAPS ITALICS</i> ... and expanded, bold , <i>italic</i> , and <i>SMALL CAPS ITALICS</i>
<i>Iwona Light Condensed</i>	Iwona Light Cond	(Encodings: T1, TS1, T2A, T2B, T2C, OT1, OT2, OT4, LY1, and TU)	
iwonalc	m, sb, b, eb, ub mx, sbx, bx, ebx, ubx	n, it, sc, scit	Regular, bold , <i>italic</i> , and <i>SMALL CAPS ITALICS</i> ... and expanded, bold , <i>italic</i> , and <i>SMALL CAPS ITALICS</i>

The series specifications in *Iwona Light* are shifted by one weight with respect to *Iwona*; e.g., m in *Iwona* becomes sb in *Iwona Light*. Similarly, the expansion codes are shifted; e.g., bx in *Iwona Condensed* is the same as b in *Iwona*. The slanted shapes (sl, scsl) are accepted but generate a warning and are then replaced by italics (it, scit).

Table 10.67: Classification of the Iwona font family

Unicode engines

For Unicode engines you need to set up the font yourself using fontspec declarations.

Iwona 10pt/12pt
(iwona) **Iwona**

With a price of £148, **almost anything** can be found FLOATING IN **FIELDS**. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phænix's official rôle* in fluffy soufflés?

10.8.19 Kp (Johannes Kepler) Sans

Kp Sans has both a matching serif and monospaced design. When used with pdf \TeX , certain features, such as special ligatures or oldstyle numerals, can be activated by altering the family name as described on page 17; you can find the description of all three families and their NFSS classifications in Table 10.9 on page 18. If used with Unicode engines, the features can be activated through the typical feature sets as supported by fontspec. An example with mathematics is shown in Figures 12.47 on page 293.

With a price of £148, **almost anything** can be found FLOATING IN
FIELDS. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often naïve
vis-à-vis the dæmonic *phænix's official rôle* in fluffy soufflés?

(jkpss) **KpSans**

10.8.20 Kurier

For her diploma in typeface design in 1975 at the Warsaw Academy of Fine Arts, Małgorzata Budyta designed the sans serif typeface Kurier with its characteristic ink traps. The family is offered in five weights and two widths and supports an extended character set including Latin and Cyrillic.

\LaTeX support for pdf \TeX is provided through the package `kurier` by Janusz Marian Nowacki (1951–2020). The default weight can be changed with the option `light`, and with `condensed` you can reduce the width. Note that the package installs the family as the document body font, i.e., as `\rmdefault`!

Matching math fonts can be activated with the option `math`. They cover the basic symbols but not those from `amssymb`, which would keep their shapes if used; see Example 12.48 on page 294.

Unicode engines

For Unicode engines you need to set up the font yourself using fontspec declarations.

Kurier is well suited as a display typeface; the example here shows the light version:

Kurier Light as heading font

Kurier Light 20pt/24pt
(kurierl) **Kurier Light**

For comparison, here are the condensed versions in body text size:

With a price of £148, **almost anything** can be found FLOATING IN FIELDS.

The series specifications in *Kurier Light* are shifted by one weight with respect to *Kurier*; e.g., m in *Kurier* becomes sb in *Kurier Light*. Similarly, the expansion codes are shifted; e.g., bx in *Kurier Condensed* is the same as b in *Kurier*. The slanted shapes (sl, scsl) are accepted but generate a warning and are then replaced by italics (it, scit).

Table 10.68: Classification of the Kurier font family

10.8.21 Latin Modern Sans

You can find the description of the Latin Modern families in Section 9.5.1 and their NFSS classifications in Table 9.6 on page →I 687.

Just like its cousin Computer Modern Sans, this family has no small capitals, and a request to `\textsc` uses Latin Modern Roman instead — a questionable choice, but consistent with the way CM fonts have been set up for decades.

(lmss) [Latin Modern Sans](#)

With a price of £148, **almost anything** can be found **FLOATING IN Fields**. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phoenix's official rôle* in fluffy soufflés?

10.8.22 Lato

Lato is a geometric sans serif design by Łukasz Dziedzic. A few years ago, the family was greatly extended with the help of Adam Twardoch and Botio Nikoltchev to cover more than 3000 glyphs and can now be used to typeset most Latin or Cyrillic-based languages, Greek, and IPA phonetics. It is offered in several weights from hairline to extra-heavy and has upright and italic shapes. `\slshape` is aliased to italics.

ℒ_ṼTeX support for all engines is provided through the package `lato` by Mohamed El Morabity. To set up Lato as the default sans serif font, use `defaultsans`. To set

Family	Series	Shapes	Typeface Examples
<i>Lato</i>	Lato (Encodings: T1, TS1, T2A, T2B, T2C, LGR, OT1, and TU)		
lato-LF	ul, el, l, m, sb, b, eb, ub	n, it, (sl)	Regular, <i>italic</i> , bold , <i>bold italics</i> , ultra-light, extra-light, light, semi-bold, extra-bold , and ultra-bold

LibreFranklin-TLF	ul, el, l, sl, m, sb, b, eb, ub	n, it, (sl)	Regular and <i>italics</i> from <i>thin</i> to ultra

Supported figure styles for Libre Franklin are -TLF and -Sup.

Table 10.70: Classification of the Libre Franklin font family

10.8.25 Lucida Sans

Lucida Sans comes with matching serif and monospaced designs, described together in Section 10.2.10 on page 21. Their NFSS classifications are given in Table 10.11 on page 22. This is the font family used in this book for package names and other items.

Lucida Sans 9pt/12pt
(hls) Lucida Sans OT

With a price of £148, **almost anything** can be found **Floating In Fields**. — ¿But aren’t Kafka’s Schloß & Æsop’s Œuvres often *naïve* vis-à-vis the dæmonic *phœnix’s official rôle* in fluffy soufflés?

10-8-2

10.8.26 Merriweather Sans

Merriweather Sans has a matching serif design. The description of both families is given on page 25 and their NFSS classifications in Table 10.12.

Merriweather Sans 9pt/12pt
(MerriwthrSans-TLF)
MerriweatherSans

With a price of £148, **almost anything** can be found **FLOATING IN FIELDS**. — ¿But aren’t Kafka’s Schloß & Æsop’s Œuvres often *naïve* vis-à-vis the dæmonic *phœnix’s official rôle* in fluffy soufflés?

10.8.27 Mint Spirit

The Mint Spirit family of fonts were originally designed by Hirwen Harendal for use as a system font on a Linux Mint system. The font combines aspects of Universalis, NeoGothis, and Gillius by the same designer and combines it with the appearance of the Ubuntu font family designed by Dalton Maag.

ℒ^AT_EX support for all engines is provided through the packages mintspirit and mintspirit2 by Bob Tennent.

Mint Spirit 10pt/12pt
(MintSpirit-OsF)
Mint Spirit

With a price of £148, **almost anything** can be found **Floating In Fields**. — ¿But aren’t Kafka’s Schloß & Æsop’s Œuvres often *naïve* vis-à-vis the dæmonic *phœnix’s official rôle* in fluffy soufflés?

Mint Spirit No2 has some slight redesigns in certain characters, i.e., “AMNVWvwy” vs. “ΑΜΝVWvwvy” (Mint Spirit), making them more conventional. The initial design certainly has its own charm (which I favor), but perhaps those of No2 blend better with the shapes of the other characters — the choice is yours.

Family	Series	Shapes	Typeface Examples
<i>Mint Spirit</i>	Mint Spirit	(Encodings: T1, TS1, OT1, LY1, and TU)	
MintSpirit-LF	m, b	n, it, (sl)	Regular, <i>italic</i> , bold , and <i>bold italic</i>

<i>Montserrat Alternates</i>	Montserrat Alternates	(Encodings: T1, TS1, OT1, LY1, and TU)	
MontserratAlternates-LF	ul, el, l, sl, m, sb, b, eb, ub	n, it, (sl), scit, (scsl)	Medium, <i>italic</i> & SMALL CAPS. Hairline to black

Supported figure styles for Montserrat and Montserrat Alternates are -LF, -OsF, -TLF, -T0sF, -Sup, and -Inf.

Table 10.72: Classification of the Montserrat font families

10.8.28 Montserrat

Montserrat is a geometric sans serif design by Julieta Ulanovsky inspired by street art from the historical Buenos Aires neighborhood of the same name. There is also a variant called Montserrat Alternates with a noticeably different design. Both fonts are offered in several weights from hairline to heavy and have upright, italic, and Small Caps shapes. `\slshape` is aliased to italics.

\LaTeX support for pdf \TeX is provided through the package `montserrat` by Michael Sharpe. It offers many options to adjust the font loading, e.g., `alternates` to use Montserrat Alternates or `defaultfam` to make the font the default document font. Use `scaled` to provide a font scaling factor and `light`, etc., to adjust the weight. For other options see the package documentation.

Unicode engines

For Unicode engines a suitable `fontspec` declarations file is provided.

For comparison we show a medium width and weight sample as well as a sample with the text in extra light and `\textbf` producing medium. This second sample runs

noticeably shorter than the first, even though both are nominally medium width:

Montserrat 10pt/12pt
(Montserrat-OsF)
Montserrat

With a price of £148, **almost anything** can be found FLOATING IN **FIELDS**. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phoenix's official* rôle in fluffy soufflés?

10.8.30 Overlock

Overlock, designed by Dario Manuel Muhafara, is a rounded sans serif typeface inspired by the Overlock sewing technique. It is offered in three weights with upright and italic shapes. Small capitals are available only in medium weight. L^AT_EX support for all engines is provided through the package `overlock` by Bob Tennent with the usual options. The package adjusts `\scshape` so that it automatically changes families behind the scenes to account for this somewhat unconventional font setup.

Overlock 10pt/12pt
(Ovr1ck-OsF) Overlock

With a price of £148, **almost anything** can be found FLOATING IN **Fields**. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phoenix's official* rôle in fluffy soufflés?

Family	Series	Shapes	Typeface Examples
Raleway	Raleway	(Encodings: T1, TS1, OT1, LY1, and TU)	
Raleway-TLF	el, l, m, sb, b, eb	n, it, (sl), sc, scit, (scsl)	Regular, <i>italic</i> , and BOLD SMALL CAPS
	t, mb, k	n, it, (sl), sc, scit, (scsl)	Also <i>some</i> nonstandard weights

Supported figure styles for Raleway are -TLF and -T0sF.
Unfortunately, the font family uses the nonstandard series names `t` (thin) and `k` (black) instead of the standard series names `ul` (ultra light) and `ub` (ultra bold). The `mb` (medium) is halfway between the standard `m` and `sb` and does not fit into the NFSS naming conventions. It can serve as a replacement for `m`, e.g., via `\DeclareFontSeriesDefault`.

Table 10.74: Classification of the Raleway font family

10.8.34 Raleway

Raleway is a sans serif display typeface, designed by Matt McInerney. In 2012 it was extended by Pablo Impallari and Rodrigo Fuenzalida to cover nine weights with upright, italic, and Small Caps shapes. With Unicode engines it offers a number of stylistic alternates inspired by more geometric sans serif typefaces than its neo-grotesque-inspired default character set. \LaTeX support for all engines is provided through the package `raleway` by Silke Hofstra.

Raleway 10pt/12pt

10.8.38 Universalis

Universalis is a legible modern style font family designed by Hirwen Harendal suitable as an alternative to designs from Adrian Frutiger (1928–2015) such as Univers or Frutiger. It is available in two weights in upright and italics and also has condensed shapes.

L^AT_EX support for all engines is provided by Bob Tennent through the package `universalis` supporting options such as `scaled`, `sfdefault`, and `condensed`.

With a price of £148, **almost anything** can be found **Floating In Fields**.
 — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the
 dæmonic *phoenix's official rôle* in fluffy soufflés?

Universalis 10pt/12pt
 (UniversalisADFStd-LF) Universalis ADF Std

The package offers the option `condensed` to use the condensed running width with all shapes.

With a price of £148, **almost anything** can be found **Floating In Fields**. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phoenix's official rôle* in fluffy soufflés?

	c, bc		Condensed, bold , <i>italic</i> , and <i>bold italic</i>

Supported figure style for Universalis is -LF.

Table 10.76: Classification of the Universalis font family

10.9 Monospaced (typewriter) fonts

The choice of monospaced (typewriter) fonts for use in program listings and other applications is not very wide though it has considerably increased in recent years. Of course, with the Computer or Latin Modern fonts a suitable typewriter family is included, but if the main document fonts are being replaced, freely available choices for typewriter fonts are still relatively few. While staying with Computer or Latin Modern Typewriter (which have an identical design) might be an option, the font may not blend well with the chosen document font.

We start with a few guidelines for selecting a suitable monospaced font and then show examples of roughly a dozen typewriter fonts to choose from.

Running length and
x-height

If you use a monospaced font mixed with your main document font, then you typically want to make it comfortably fit in by not showing large deviations from the normal running length nor from the x-height of your body font. The following example compares LuxiMono (scaled down to 85% using the option `scaled`), Computer Modern Typewriter, and Adobe Courier (or more precisely T_EX Gyre Cursor). Among those three, LuxiMono has the largest x-height (`\fontdimen5`) and, at the same time, the smallest width. Courier, running very wide, occupies the other end of the spectrum, with CM Typewriter being comfortably in between the two extremes.

LuxiMono:	<code>\usepackage[T1]{fontenc}</code>
The dazed brown fox quickly gave 12345-67890	<code>\usepackage[scaled=0.85]{luximono}</code>
jumps! x-height=4.50502pt	<code>\newcommand\allletters{The dazed brown</code>
CM Typewriter:	<code>fox quickly gave 12345--67890 jumps!</code>
The dazed brown fox quickly gave 12345-67890	<code>x-height=\the\fontdimen5\font\ }</code>
jumps! x-height=4.3045pt	<code>\raggedright</code>
Adobe Courier:	<code>\texttt{LuxiMono:\ \allletters}</code>
The dazed brown fox quickly gave	<code>\par \renewcommand\ttdefault{cmtt}</code>
12345-67890 jumps! x-height=4.17pt	<code>\texttt{CM Typewriter:\ \allletters}</code>
	<code>\par \renewcommand\ttdefault{qcr}</code>
	<code>\texttt{Adobe Courier:\ \allletters}</code>

10-9-1

Besides choosing a font with a suitable running length and x-height, it is often also important to use one that shows characteristically different designs in letters that are otherwise easily mistaken for another. Especially in code display this might

Family	Series	Shapes	Typeface Examples
Algol	AlgolRevived	(Encodings: T1, TS1, OT1, LY1, and TU)	
AlgolRevived-TLF	m, sb, (b)	n, sl, (it)	Regular, <i>slanted</i> , and semi bold

Supported figure styles for AlgolRevived are -TLF, -Sup, and -Inf.

Table 10.77: Classification of the AlgolRevived font family

lead to confusion if they look similar or even identical. For this reason all the samples in this section show the text “OI1 or 011?” so that you can judge for yourself how well Capital O differs from 0 (zero) and Capital I is distinguishable from lowercase l as well as from the digit 1. Charles Bigelow has written an interesting article on the subject that discusses how font designers struggled through the centuries with this problem and shows their solutions [20].

⚠ Watch out
for confusingly
similar character
shapes

Another important aspect to check is whether or not the monospaced font contains ligatures that have been set up for use with T_EX. While using ligatures is normally a sign of high typographical quality and it is great that T_EX does this automatically, this is not wanted with monospace fonts; in fact in a line like

⚠ Beware
of bad ligatures

Often we *officially* find offers floating in far offline fjords.

the “fi” and “fl” ligatures look rather out of place, especially as the “ffi” and “ffl” ligatures are missing in this particular font. Unfortunately, in older font setups of some fonts, they have been incorrectly added. If that is the case, you have to obtain newer releases of the font support files, or disable the ligatures with the help of the microtype package; see Section 3.1.3 on page →I 135.

Finally, the different shapes of monospaced fonts do not always have the same running width; e.g., regular and bold may both be monospaced, but mixing them may mean that characters are no longer vertically aligned. If this is the case, the font may not be suitable at all¹ or only if you stick to a single (typically the regular) shape. This was the case with the Libertinus fonts in the past but is now corrected. It can also happen when you use the microtype package, and it does not realize that it is a monospaced font that should not be expanded or compressed. If typewriter material does not line up as expected, disable the package and see if that was the cause. If so, you need to explicitly instruct microtype how to handle your font.

⚠ Fonts may just
claim to be fully
monospaced

10.9.1 Algol

Algol is a font by Adrian Frutiger (1928–2015) that was designed for printing Algol code in manuals; i.e., it is not really meant to be a general-purpose text font. One

¹This is, for example, the case with URW Letter Gothic, which is a nice sans serif monospaced font, except that it adds some kerning between a few letters in the version on CTAN, making it basically unsuitable for any purpose.

Family	Series	Shapes	Typeface Examples
<i>Anonymous Pro</i>	Anonymous Pro	(Encodings: T1, TS1, OT1, and TU)	
AnonymousPro	m, b	n, sl, (it), (sc)	Regular, <i>italic</i> , bold italic , and BOLD SMALL CAPS
There is also a U encoding for a few symbols.			

Table 10.78: Classification of the Anonymous Pro font family

interesting aspect of it is that it is actually not a monospaced font¹ — so use it only for typewriter if you do not require that all characters line up.

It was digitalized and prepared for use with \LaTeX by Michael Sharpe under the name Algol Revived. Note that his `algolrevived` package sets up the font for use as the document font, unless you give it the option `tt!` With `medium` you select the medium bold series as the default, and with `scaled` you can supply a scale factor as usual. The package also defines a few additional text symbols; see its documentation for details.

With a price of £148, **almost anything** can be found **Floating In Fields**. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often naïve vis-à-vis the dæmonic *phænix's official rôle* in fluffy soufflés? OIl or 011?

10.9.2 Anonymous Pro

Anonymous Pro is a monospaced font family designed by Mark Simonson. Special care has been taken to make it suitable for code display by giving glyphs that could be mistaken for each other distinct shapes (such as zero and capital O, etc.).

\LaTeX support for pdf \TeX is provided through the package `AnonymousPro` by Arash Esbati. With the option `scaled`, you can specify a scale factor for the font. The package also defines a number of command names to access extra symbols, many of which represent Apple keyboard keys, such as `Apple` `↩` `⌘` `⌥`, as well as a few others. Note that the small capitals are faked and appear much too thin.

—no OpenType—

10.9.4 Courier

Courier is a wide-running, thin-stroked monospaced font. It was designed by Howard Kettler (1919–1999) of IBM and later redrawn by Adrian Frutiger (1928–2015). These days it is often used in combination with Times Roman, producing a striking contrast. One reason for the popularity of this combination is certainly its availability on any PostScript device.

T_EX Gyre Cursor shown here is based on the URW Nimbus Mono L version of the font family (which is set up with the T_EX Gyre tgcursor package).

Œuvres often *naïve* vis-à-vis the dæmonic *phænix's*
official rôle in fluffy soufflés? OIl or 011?

10.9.8 Inconsolata

Inconsolata is a monospaced sans serif font designed by Raph Levien. It is provided in regular and bold weights but offers only a single shape, e.g., no italics, etc. By default, word spaces are flexible; i.e., only the characters are monospaced and thus can be used justified.

LaTeX support for pdfTeX is provided through the package inconsolata by Michael Sharpe. It offers a bundle of options, e.g., `scaled`, `narrow` (for a somewhat condensed width), `hyphenate` (allow hyphenation), `mono` (make word spaces also mono-width), and several others. Support for a number of variant characters such as a nonslashed zero is also provided through options. See the package documentation for details.

Unicode engines

For Unicode engines some fontspec configuration files are provided.

With a price of £148, **almost anything** can be found **Floating In Fields**. – ¿But aren't Kafka's Schloß & Æsop's Œuvres often naïve vis-à-vis the dæmonic phœnix's official rôle in fluffy soufflés? OIl or 011?

Inconsolata 10pt/12pt
(zi4) [Inconsolatazi4](#)

10.9.9 Kp (Johannes Kepler) Typewriter

Kp Mono has both a matching serif and sans serif design. All three families are described on page 17 where you also find their NFSS classifications in Table 10.9 on page 18. An interesting aspect of the font is that it offers both lining and oldstyle numbers (as shown below). If you prefer lining numerals, use the family jkptt with pdfTeX; with Unicode engines use the feature set of fontspec.

With a price of £148, **almost anything** can be found **Floating In Fields**. -- ¿But aren't Kafka's Schloß & Æsop's Œuvres often naïve vis-à-vis the dæmonic phœnix's official rôle in fluffy soufflés? OIl or 011?

Kp Mono 10pt/12pt
(jkpttosn) [KpMono](#)

10.9.10 Latin Modern Typewriter

If you load the lmodern package, all fonts are going to be from the Latin Modern families. On the Unicode engines Latin Modern is already the default, so you do not even have to load a package.

In either case, this means that `\texttt` selects the regular monospaced version of the Latin Modern Typewriter font. You can find the description of the Latin Modern families in Section 9.5.1 and their NFSS classifications in Table 9.6 on page 1687.

With a price of £148, **almost anything** can be found **FLOATING IN Fields**. – ¿But aren't Kafka's Schloß & Æsop's Œuvres often naïve vis-à-vis the dæmonic phœnix's official rôle in fluffy soufflés? OIl or 011?

LM Typewriter 10pt/12pt
(lmtt) [Latin Modern Mono](#)

As we have seen in that section, this font actually has several weights, as well as a proportional variant, in addition to the monospaced one. To be able to easily provide access to these variants within a document, as well as setting up any of them as default just for the typewriter font, Michael Sharpe produced the package `zlm` that you can use instead or in addition to `lmodern`.

The package has a number of options, such as `light` or `lightcondensed` to choose the light weight as default, as well as `med` to use the medium weight when bold is requested. Furthermore, the option `proportional` requests the proportionally spaced version instead of the default monospaced one, and `scaled` applies a scale factor, which helps if you combine the font with other families.

The package also offers the commands `\monott`, `\proptt`, and `\lctt` to unconditionally select the monospaced, proportionally, or light condensed version of the font regardless of the options chosen during package loading.

The example below shows the result of these commands in different circumstances. The default here is the light proportional version; thus, we see no change when we explicitly request proportional for the second sentence. `\monott` then forces monospaced glyphs. Then we switch explicitly to light condensed. As you see, that has italics, but the bold comes out in normal running length as there is not a bold condensed series. Finally, in the last line we use `\texttt` again, which switches back to the document default but still keeps the italic shape that was requested earlier.

<p>The dazed brown fox <i>quickly</i> gave 12–3 jumps! (proportional)</p> <p>The dazed brown fox <i>quickly</i> gave 12–3 jumps! (no change)</p> <p>The dazed brown fox <i>quickly</i> gave 12–3 jumps! 10.9.13 Luximono

The Luximono fonts are original designs by Kris Holmes and Charles Bigelow (Bigelow and Holmes, Inc.), for which hinting and kerning tables have been added by URW++ Design and Development GmbH. The family has two weights with upright and oblique shapes. In that respect, it differs from other monospaced fonts, which are often offered only in medium series and more rarely in italic or oblique shapes.

With a price of £148, **almost anything** can be found **Floating In Fields**. -- ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phænix's official rôle* in fluffy soufflés? OIl or O11?

Luximono 9pt/12pt
(ul9) —no OpenType—

The L^AT_EX integration for pdfT_EX is provided through the luximono package written by Walter Schmidt (1960-2021). If the option scaled is given without a value,

the fonts are loaded at a running length approximately equal to that of Computer Modern Typewriter. Without scaling, LuxiMono has the same running length as Adobe Courier. The fonts are not included in all distributions but can be installed with `getnonfreefonts`.

10.9.14 Noto Sans Mono

The Noto Sans Mono fonts (and the earlier version Droid Sans Mono) have matching serif and sans serif designs. They are described on page 26, and the NFSS classification is given in Table 10.14 on page 28.

Noto Sans Mono 9pt/12pt

10.10 Historical and other fonts

The fonts that we are going to showcase in this section are a mixed bunch that for one or another reason did not fit well into the classification that we used above. A few are historically before the periods covered, e.g., Cinzel and Marcellus that are based on 1st century roman inscriptions. The Blackletter shapes that we cover briefly at the end were the first fonts used as movable type and thus represent the period before the Humanist fonts took over. Because they are useful only in special circumstances, we cover them here.

On the other side of the spectrum are the Chancery and handwriting fonts that are in some sense the predecessors of what we nowadays call the italic shape because the glyph forms were originally developed in the Vatican in the 15th century based on the Humanist minuscule of that time.

Two of the families inspired by chancery handwriting, Almendra and Antykwa Toruńska, are explicitly intended for body text (though they work nicely in display sizes too). Due to their stronger personality, they are suitable only in a few scenarios, which is why they are also placed in this section.

The actual fonts that we exhibit here are — with one exception — all contemporary and have been designed in the last or even in this century. The exceptions are the Fell types, which are digitalized versions of the 17th century originals, charmingly showing all the imperfections of the original type.

Family	Series	Shapes	Typeface Examples

<i>Marcellus</i>	Marcellus	(Encodings: T1, TS1, OT1, LY1, and TU)	
Mrcls-LF	m	n, sc	Regular and SMALL CAPS SHAPES only

Supported figure styles for Marcellus are -LF and -Sup.

Table 10.83: Classification of the Marcellus font family

10.10.1 Cinzel

The classical proportions of the Cinzel fonts are inspired by 1st century roman inscriptions. Designed by Natanael Gama, the fonts are available in three different weights (but naturally, without italics, which is an invention of the 15th century).

TeX support for all engines is provided through the package cinzel by Bob Tennent. If the option default is given, \rmdefault is changed to select the family. In any case, the font is made available through the commands \textcinzel and \textcinzelblack or the declarations \cinzel and \cinzelblack.

Cinzel 10pt/12pt
(Cinzel-LF) Cinzel

WITH A PRICE OF £148, **ALMOST ANYTHING** CAN BE FOUND
FLOATING IN **FIELDS**. — ¿BUT AREN'T KAFKA'S SCHLOSS & ÆSOP'S
ŒUVRES OFTEN **NAÏVE** VIS-À-VIS THE DÆMONIC **PHŒNIX'S**
OFFICIAL RÔLE IN FLUFFY SOUFFLÉS?

Upper and lowercase letters in Cinzel Decorative have the same height, but only the uppercase glyphs have decorations; thus, when used with only some letters uppcased, it gives some interesting results.

Cinzel Decorative
10pt/13.6pt
(CinzelDecorative-LF) Cinzel Decorative

ALL UPPERCASE: ABCDEFGHIJKLMNOPQRSTUVWXYZ
MIXED CASE: THE DAZED BROWN FOX QUICKLY GAVE 123 JUMPS!

If the cinzel package is used, then \textit or the declaration \itshape switches to the decorative font as long as you are currently typesetting in Cinzel.

<i>Fell Types</i>	IM FELL English	(Encodings: T1, TS1, OT1, LY1, and TU)	
IMFELLEnglish-TLF	m	n, it, (sl), sc	Fell regular, <i>italic</i> , and SMALL CAPS shapes

The family has oldstyle numbers despite the fact the suffix -TLF.

Table 10.84: Classification of the Fell Types

10.10.2 Marcellus

Like Cinzel, the Marcellus fonts by Brian J. Bonislawsky are also inspired by classical roman inscriptions. The small capitals are well suited for display text, while the regular version lends itself to a wider range of usage having both capitals and lowercase letters. Note, though, that this family is offered only in regular weight and does not provide any italics.

LaTeX support for all engines is provided through the package `marcellus` by Bob Tennent with the option `scaled` providing a scale factor.

With a price of £148, almost anything can be found FLOATING IN Fields. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often naïve vis-à-vis the dæmonic phoenix's official rôle in fluffy soufflés?

Marcellus 10pt/12pt
(Mrc1s-LF) Marcellus

10.10.3 The Fell Types

The so-called Fell Types, which are of Dutch origin, were in use in the 17th century at the Oxford University Press. They have been procured by Dr. John Fell, Bishop of Oxford and Dean of Christ Church, who also collected an impressive number of ornamental flower specimen. The fonts have been digitalized by Iginio Marini,¹ and LaTeX support for all engines is available through the package `imfellEnglish` by Bob Tennent. The sample shows the fonts at their nominal font size of 13.5pt.

With a price of £148, almost anything can be found FLOATING IN Fields. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often naïve vis-à-vis the dæmonic phoenix's official rôle in fluffy soufflés?

Fell 13.5pt/15pt
(IMFELLEnglish-TLF)
IM FELL English

Unicode engines

With Unicode engines it is also possible to access the ornamental flower designs collected by Dr. Fell, as shown in the next example. They are available from CTAN but normally not distributed. Thus, you have to download them first, either from there or from the designer's home page.

¹ See the <https://www.iginomarini.com> website.

10-10-1

10.10.4 Almendra

The Almendra family, designed by Ana Sanfelippo, is a typeface inspired by chancery and gothic handwriting. It was exhibited at the Bienal Iberoamericana de Dise~no in 2010 and was part of the German editorial project Typodarium 2012. The font is intended for body text but also works nicely in display sizes. One of its unusual features is that its italics are upright.

LaTeX support for all engines is provided through the package `almendra` by Bob Tennent. With the option `scaled` you can provide a scale factor.

;But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic
phœnix's official rôle in fluffy soufflés?

10.10.5 Antykwa Toruńska

Antykwa Toruńska, which means “Antiqua of Toruń”, was designed by Zygfryd Gardzielewski, a typographer from the city of Toruń¹ (Thorn), Poland. Some of its characteristic features are the widening of its stems towards the top and the wave-like form of some of the horizontal and diagonal lines as well as the form of its serifs. It was first cut in metal in 1960 in Warsaw and digitalized in 2005 by Janusz Marian

¹The birthplace of Nicolaus Copernicus (Mikołaj Kopernik).

Family	Series	Shapes	Typeface Examples
<i>Antykwa Toruńska</i>			
		Antykwa Torunska	(Encodings: T1, TS1, T5, OT1, OT4, LY1, and TU)
antt	l, m, sb, b	n, it, sc, scit	Regular bold , <i>italic</i> , and <i>SMALL CAPS ITALICS</i>
	lc, c, sbc, bc		Condensed bold , <i>italic</i> , and <i>SMALL CAPS ITALICS</i>
<i>Antykwa Toruńska Light</i>			
		Antykwa Torunska Light	(Encodings: T1, TS1, T5, OT1, OT4, LY1, and TU)
anttl	m, sb, b, eb	n, it, sc, scit	Regular, bold , <i>italic</i> , and <i>SMALL CAPS ITALICS</i>
	c, sbc, bc, ebc		Condensed regular, bold , <i>italic</i> , and <i>SMALL CAPS ITALICS</i>
<i>Antykwa Toruńska Condensed</i>			
		Antykwa Torunska Cond	(Encodings: T1, TS1, T5, OT1, OT4, LY1, and TU)
anttc	l, m, sb, b	n, it, sc, scit	Regular, bold , <i>italic</i> , and <i>SMALL CAPS ITALICS</i>
	lx, x, sbx, bx		Expanded regular, bold , <i>italic</i> , and <i>SMALL CAPS ITALICS</i>
<i>Antykwa Toruńska Light Cond.</i>			
		Antykwa Torunska Light Cond	(Encodings: T1, TS1, T5, OT1, OT4, LY1, TU)
anttlc	m, sb, b, eb	n, it, sc, scit	Regular, bold , <i>italic</i> , and <i>SMALL CAPS ITALICS</i>
	x, sbx, bx, ebx		Expanded, bold expanded , <i>italic</i> , and <i>SMALL CAPS ITALICS</i> & extra-bold expanded

The series specifications in *Antykwa Toruńska Light* are shifted by one weight with respect to *Antykwa Toruńska*; e.g., *m* in *Antykwa Toruńska* becomes *sb* in *Antykwa Toruńska Light*. Similarly, the expansion codes are shifted; e.g., *bx* in *Antykwa Toruńska Condensed* is the same as *b* in *Antykwa Toruńska*.

Table 10.86: Classification of the Antykwa Toruńska font family

Nowacki (1951–2020). It is offered in five weights and two widths. Note that there is no `\slshape`.

LaTeX support for pdfTeX is provided through the package `antt` by Janusz Marian Nowacki (1951–2020). The standard weight can be selected through the options `regular` (default) and `light`, and with `condensed` you can reduce the width.

Matching math fonts are available too and can be activated with the option `math`. They cover the basic symbols but not those from `amssymb`, which would keep their shapes if used; see Figures 12.51 to 12.52 on page 296.

Unicode engines

For Unicode engines you need to provide your own `fontspec` declaration.

With a price of £148, **almost anything** can be found FLOATING IN **FIELDS**. — ¿But aren’t Kafka’s Schloß & Æsop’s Œuvres often *naïve* vis-à-vis the dæmonic *phœnix’s official rôle* in fluffy soufflés?

10.10.6 Lucida Casual, Calligraphy, and Handwriting

In the Lucida set of fonts sold by TUG there are three typefaces that are inspired in varying degrees by handwriting. You can find their NFSS 10.11 on page 22 together with those of other Lucida families. Lucida Casual supports upright and italic shapes; the others only italics as is typical for handwritten fonts.

Lucida Casual 9pt/12pt

10.10.7 Zapf Chancery (T_EX Gyre Chorus)

Zapf Chancery is another and quite famous contemporary script based on chancery handwriting, as developed during the Italian Renaissance for use by the scribes in the papal offices. Highly legible, it can be usefully applied for short texts and applications like invitations and awards.

T_EX Gyre Chorus shown here is based on the URW Chancery L Medium Italic version of the font (which is set up by the T_EX Gyre tgchorus package). Note that this font is available only in an italic shape, which is why the sample text does not show any bold or small capitals.

ITC Zapf Chancery 10pt/12pt
(qzc) TeX Gyre Chorus

With a price of £148, almost anything can be found Floating In Fields. — ¿But aren't Kafka's Schloß & Æsop's Œuvres often *naïve* vis-à-vis the dæmonic *phœnix's official rôle* in fluffy soufflés?

fmm	m	n, (it), (sl), (sc)	<i>Miama Nueva handwriting</i>

Table 10.88: Classification of the Miama Nueva family

10.10.8 Miama Nueva

This typeface, designed by Linus Romer, also mimics handwriting and offers a large glyph set that supports the Latin, polytonic Greek, and Cyrillic scripts. The *miama* package for the pdfT_EX engine supports the option `scaled` to provide a scaling factor and offers the command `\miama` and the declaration `\fmmfamily` to select the font — document font defaults are not changed. Thus, if you want to typeset a whole document in this hand, use `\fmmfamily`, and if you cannot stop talking about T_EX or L^AT_EX in your invitation letter, then `\fmmTeX` and `\fmmLaTeX` provide you with a way, as the standard commands do not work well in this font.

Unicode engines

With Unicode engines, use `fontspec` to set up the font.

*With a price of £148, almost anything can be found Floating In
Fields. — ¿But aren't Kafka's Schloß & Aesop's Œuvres often naïve
vis-à-vis the daemonic phoenix's official rôle in fluffy soufflés?
Also supported: T_EX and L^AT_EX instead of T_EX and L^AT_EX*

Miama Nova 9pt/20pt
(fmm) Miama Nueva

The font has roughly the same x-height as Computer Modern, but due to the long ascenders and descenders, you need to either scale it down or enlarge the leading to avoid that characters run into each other. In the above example, we therefore changed from the usual 9/11 pt to 9/20 pt.

10.10.9 Lucida Blackletter

The Lucida set of fonts as sold by TUG also contains a blackletter font, which is primarily meant to be used in math (at least when using pdfTeX) and not in text as we do here. See Section 10.2.10 on page 25 for a discussion of why.

Lucida Blackletter 9pt/12pt
(hlcf)

Lucida Blackletter OT

But aren't Kafka's Schloß & Esop's Œuvres often *naïve* vis-à-vis the *dæmonic*
phœnix's official rôle in fluffy soufflés?

10.10.10 Blackletter — Yannis Gothic, Schwabacher, and Fraktur

There exists a set of beautiful fonts for typesetting in Gothic, Schwabacher, and Fraktur designed in METAFONT after traditional typefaces by Yannis Haralambous [66]. The collection also contains a font with baroque initials. These days Type 1 versions of the fonts are available as well that are automatically used.

LaTeX support for all engines is provided through the yfonts package written by Walter Schmidt (1960–2021). This package internally defines some local encodings (i.e., even on Unicode engines it does not use fontenc) that reflect the special features found in the fonts and integrates them fully with LaTeX's font management.

The commands `\gothfamily`, `\swabfamily`, and `\frakfamily` switch to Gothic, Schwabacher, and Fraktur, respectively. The corresponding commands with one argument are `\textgoth`, `\textswab`, and `\textfrak`. If one wants to typeset a whole document in such a typeface, the corresponding command should be used directly *after* `\begin{document}`. Because of the nonstandard encodings of the fonts, redefining the document defaults (e.g., `\familydefault`) is not possible. In addition to the font switches, the usual `\text..` commands for typesetting short fragments are provided.

The package provides *Gotisch*, also called *Textur*, *Schwabacher*, and *Fraktur* typefaces, also generally known as „*gebrochene Schriften*“.

```
\usepackage{yfonts}\usepackage[document]{ragged2e}
```

The package provides `\textgoth{Gotisch}`, also called `\textswab{Schwabacher}`, and `\textfrak{Fraktur}` typefaces, also generally known as `\textfrak{‘ge-bro- che- ne Schriften’}`.

10-10-2

The fonts are available in the usual LaTeX sizes starting from 10pt so that size-changing commands (e.g., `\normalsize` and larger) work. There are, however, no further font series or shapes, so commands like `\emph`, `\textit`, and `\textbf` have no effect other than producing a warning. Following historical practice, you can use Schwabacher to emphasize something inside text typeset in Fraktur.

For accented characters one can use the standard LaTeX representations (e.g., either Unicode characters¹ or `\"a` for ä, etc.). To facilitate easy input (long before Unicode became common), the fonts also contain ligatures that represent umlauts (e.g., "a). In Fraktur and Schwabacher there also exist alternate umlauts, which can be accessed with `*a` and similar ligatures. If the yfonts package is loaded with the option `varumlaut`, then the variant glyphs are selected automatically. All three fonts contain a glyph for the “short s”, accessed through the ligature `s:`; and “sharp s”, accessed by “ß”, `\ss`, through the ligature `sz`, or through `"s`.

¹However, strangely enough this only works in pdfTeX and *not* in Unicode engines!

The next example shows the various ligatures. With pdfTeX one can use the Unicode characters ÄÖÜäöüß directly and only needs the “short s” ligature. However, due to the special font encoding this *does not work* in Unicode engines — with these engines you have to enter the accents as ligatures or LaTeX commands.

10-10-3

Fraktur: ä ë ü ö ä é û ó ß f vf. ſ
Swab: ä ë ü ö ä é û ó ß f vf. ſ
Gothic: ä ë ü ö (unavail) k l bl. ſ

```
\usepackage{yfonts}
\Large \frakfamily Fraktur: "a "e "u "o
\hfil *a *e *u *o \hfil sz \hfil s vs.\ s:
\par\swabfamily Swab: "a "e "u "o
\hfil *a *e *u *o \hfil sz \hfil s vs.\ s:
\par\gothfamily Gothic: "a "e "u "o
\hfil (unavail) \hfil sz \hfil s vs.\ s:
```

The font selected with `\gothfamily` is not a copy of Gutenberg’s font used for his Bible (which had 288 glyphs altogether), but it follows Gutenberg’s guidelines on lowercase characters and implements as many ligatures as can be fit into a 7-bit font (e.g., the “va” in the previous example). For this reason many standard ASCII symbols are unavailable in this font.

The two other fonts also implement only a subset of visible ASCII. Problematic are the semicolon (which is missing in Schwabacher) and the characters +, =, `, [,], /, *, @, &, and % (which either are missing or produce wrong or nonmatching shapes). Their omission is seldom a problem, because typically they are not needed in documents using such fonts. However, one needs to be aware that no warning or error message is issued if they are used — the only indication is missing or wrong glyphs in the printed output!

10-10-4

Symbols: + = ‘ [] / * \$ % & ; @
 Fraktur problems: + = ‘ [] / * \$ % & ;
 Swab problems: + = ‘ [] / * \$ %
 Gothic problems: ffi tt s ä ö ffi tt \$ ff ;

```
\usepackage{yfonts}
\newcommand\test{+ = ‘ [ ] / * \$ \% \& ; @}
Symbols: \ttfamily \test \par
\frakfamily Fraktur problems:: \test \par
\swabfamily Swab problems:: \test \par
\gothfamily Gothic problems:: \test
```

The default line spacing of the standard classes is too large for the blackletter fonts. For this reason the package implements the `\fraklines` command, which selects a suitable `\baselineskip` for Fraktur or Schwabacher. It must be repeated after every size-changing command.

The font collection also contains a font with decorative initials, as shown in the next example. Note the use of Unicode characters and the option `varumlaut`:

10-10-5

ies ist ein Blindtext an dem sich verschiedene Dinge ablesen lassen. Der Grauwert der Schriftfläche wird sichtbar und man kann an ihm prüfen, wie gut die Schrift zu lesen ist und wie sie auf den Leser wirkt. Bei genauerem Hinsehen werden die einzelnen Buchstaben und ihre Besonderheiten erkennbar, etc

```
\usepackage[german]{babel} \usepackage{color}
\usepackage{varumlaut}{yfonts}
\frakfamily\fraklines
\yinipar{\color{blue}D}ies: ist ein Blindtext an dem
sich verschiedene Dinge ablesen lassen. Der Grauwert
der Schriftfläche wird sichtbar und man kann an ihm
prüfen, wie gut die Schrift zu lesen ist und wie sie
auf den Leser wirkt. Bei genauerem Hinsehen werden
die einzelnen Buchstaben und ihre Besonderheiten
erkennbar, \etc
```

The command `\yinipar` used in the previous example starts a new paragraph without indentation, producing a baroque dropped initial. For this command to work, a full paragraph (up to and including the next blank line or `\par`) must be typeset using `\fraklines`. Otherwise, the space left for the initial is either too large or too small.

As an alternative, you can access these initials with the `\textinit` command or the font switch `\initfamily`, in which case initials aligned at the baseline are produced. The example also used the command `\etc`, which produces a once-popular symbol for “etc.”; it is available in Fraktur only.

The font collection contains a second Fraktur font that has slightly wider glyphs with, at the same time, slightly thinner stems. It can be selected by redefining `\frakdefault` as shown in the next example. When compared to Example 10-10-5, the difference in running length can be clearly observed, resulting in an overfull box on the third line.

ies ist ein Blindtext an dem sich verschiedene Dinge ablesen lassen. Der Grauwert der Schriftfläche wird sichtbar und man kann an ihm prüfen, wie gut die Schrift zu lesen ist und wie sie auf den Leser wirkt. Bei genauerem Hinsehen ...

```
\usepackage[german]{babel} \usepackage{color}
\usepackage[varumlaut]{yfonts}
\renewcommand\frakdefault{\ysmfrak}
\frakfamily\fraklines
\yinipar{\color{blue}D}ies: ist ein Blindtext an dem
sich verschiedene Dinge ablesen lassen. Der Grauwert
der Schriftfläche wird sichtbar und man kann an ihm
prüfen, wie gut die Schrift zu lesen ist und wie
sie auf den Leser wirkt. Bei genauerem Hinsehen \dots
```

10-10-6

10.11 Fonts supporting Latin and polytonic Greek

The Greek Font Society (GFS), a nonprofit organization in Greece devoted to improving Greek digital typography, made a larger number of fonts with support for the Greek language publicly available. Antonis Tzolomitis and others adapted several of them for use with pdf_T_EX. Besides support for polytonic Greek, some of these fonts also contain a full set of Latin glyphs — those have been shown already in the previous sections. If you are primarily interested in typesetting in polytonic Greek, then a few more GFS fonts exist that support only the Greek language.¹

Some of the fonts from the previous sections also offer polytonic Greek in addition to Latin, and for a quick comparison all of them are shown here once more with a short sample text exhibiting English and Greek together (and bold, italic, and small capitals if available). Small capitals are often not implemented for Greek letters (even if available for Latin), and in some cases only characters without diacritics are available.

The standard encoding for Greek is called LGR and listed in this way in the tables throughout this chapter, but note that not all fonts that claim to support this encoding offer polytonic Greek; some provide only basic glyphs without diacritics. Such fonts are not listed below.

¹The relevant support packages are `gfsbaskerville`, `gfscomplutum`, `gfsponson`, and `gfsosolomos`.

10.11.1 Serif designs

Alegreya is fairly complete so can serve as a sample for the different font faces.

Once said the great poet Constantin CAVAFY: Σὰ βγεῖς στὸν πηγαῖμὸ γιὰ τὴν Ἰθάκη, νὰ εὐχέσαι νᾶναι μακρὺς ὁ δρόμος, γεμᾶτος περιπέτειες, γεμᾶτος ΓΝΩΣΕΙΣ (When you set out on the journey to **Ithaca**, pray that road be *long*, full of adventures, full of KNOWLEDGE). — See page 11 for font family details.

Alegreya 10pt/12pt
(Alegreya-0sF) **Alegreya**

Cambria is a commercial TrueType font that ships with Windows and Office products; thus, many people have them on their system. The Greek small capitals are not complete as you can observe in the sample.

Once said the great poet Constantin CAVAFY: Σὰ βγεῖς στὸν πηγαῖμὸ γιὰ τὴν Ἰθάκη, νὰ εὐχέσαι νᾶναι μακρὺς ὁ δρόμος, γεμᾶτος περιπέτειες, γεμᾶτος ΓΝΩΣΕΙΣ. — See page 49 for font family details.

Cambria 10pt/12pt
(— only TrueType —)
Cambria

10-11-1

Cochineal has issues with the “Iota with Psili”; the spacing is wrong. There is also no Small Caps shape with Greek — a restriction shared with many other font families.

Once said the great poet Constantin CAVAFY: Σὰ βγεῖς στὸν πηγαῖμὸ γιὰ τὴν Ἰθάκη, νὰ εὐχέσαι νᾶναι μακρὺς ὁ δρόμος, γεμᾶτος περιπέτειες, γεμᾶτος γνώσεις. — See page 40 for font family details.

10.12 Fonts supporting Latin and Cyrillic

In this section we exhibit fonts that support both Latin and Cyrillic alphabets. The sample text shows bold, italic, and small capitals when available. If not, it is highlighted as usual. Many of these fonts also support polytonic Greek shown in the previous section, but often there are some restrictions, either with the Cyrillic or with the Greek support with respect to available shapes.

10.12.1 Serif designs

Cambria is a commercial TrueType font that ships with Windows and Office products; thus, many people have them on their system.

10.13 The L^AT_EX world of symbols

Shortly after T_EX and METAFONT came into existence, people started to develop new symbol fonts for use with the system. Over time the set of available symbols grew to a considerable number. The *Comprehensive L^AT_EX Symbol List* by Scott Pakin [161] lists more than 18000 symbols on 422 pages¹ and the corresponding L^AT_EX commands that produce them. For some symbols the necessary fonts and support packages may have to be obtained (e.g., from a CTAN host; see Appendix C.4.1) and installed by the user. They are usually accompanied by installation instructions and general documentation.

Obviously, the few fonts and packages described in this section form only a small subset of what is available. If you cannot find a symbol here, the 422 pages of [161] are a valuable resource for locating what you need.

There are also a few online resources that can be very helpful: you draw the symbol that you are looking for with your mouse and get back possible suggestions. Especially for L^AT_EX there is <https://detexify.kirelabs.org/classify.html>² by Daniel Kirsch that reports back the L^AT_EX command name (and any necessary package information), and if you want to hunt for some unusual Unicode character, then <http://shapecatcher.com/> is worth a try as it knows about a large number of shapes.

*Online resources
for finding L^AT_EX
symbols*

We start by looking at the pifont package that offers some generic support to symbol fonts that are offered in U encoding. This is followed by a small number of interesting symbol fonts, including two that contain ornaments for page borders and similar applications. The chapter concludes with an introduction to the TIPA system, which provides support for phonetic symbols.

All packages and fonts listed in this section and in [161] are freely available: in one or two cases you need to install the support files using `getnonfreefonts`.

10.13.1 pifont — Accessing Pi and Symbol fonts

Fonts containing collections of special symbols, which are normally not found in a text font, are called Pi fonts. One such font, the PostScript font Zapf Dingbats, is available if you use the pifont package originally written by Sebastian Rahtz (1955–2016).

The directly accessible characters of the PostScript Zapf Dingbats font are shown in Table 10.89 on the following page. A given character can be chosen via the `\ding`

*Accessing glyphs
from Zapf Dingbats*

¹Counted in 2022.

²For the Macintosh this also exists as a local App that does not need an Internet connection.

Table 10.89: Glyphs in the PostScript font Zapf Dingbats

command. The parameter for the `\ding` command is an integer that specifies the character to be typeset according to the table. It can also be specified as an octal value (preceding it with `'`) or very conveniently as a hexadecimal (preceding it with `"`) as this matches the way font tables are usually organized. For example, `\ding{"A1}` gives ♫, and you can find that number immediately when looking at the font table.

The `dinglist` environment is a variation of the `itemize` list. The argument specifies the number of the character to be used at the beginning of each item.

➤ The first item.

➤ The second item in the list.

➤ A final item.

```
\usepackage{pifont}
\begin{dinglist}{"E4}
  \item The first item.
  \item The second
    item in the list.
  \item A final item.
\end{dinglist}
```

10-13-1

The environment `dingautolist` allows you to build an enumerated list from a sequence of Zapf Dingbats characters. In this case, the argument specifies the number of the first character of the sequence. Subsequent items are numbered by incrementing this number by one. This makes some starting positions like "AC, "B6, "C0, and "CA (i.e., in hexadecimal notation) in Table 10.89 very attractive, as differently designed circled number sequences (1-10) start there.

① The first item in the list.

② The second item in the list.

③ The third item in the list.

```
\usepackage{pifont}
\begin{dingautolist}{"C0}
  \item The first item in the list.\label{lst:a}
  \item The second item in the list.\label{lst:b}
  \item The third item in the list.\label{lst:c}
\end{dingautolist}
```

References to list items work as expected: ①,
②, ③

References to list items work as expected:
`\ref{lst:a}`, `\ref{lst:b}`, `\ref{lst:c}`

10-13-2

	0	1	2	3	4	5	6	7	8	9	A	B	C	D	E	F
U+0000–000F	🍏	🍏	≈	⏪	◆	✓	🏠	...	↩	👉	≥	ℙ	ℎ	∞	↵	∫
U+0010–001F	≤	◇	≠	˘	∂	Π	π	Π	♠	♠	Σ	σ	ς	Σ	⇒	↺
U+0020–002F	˘	ˆ	⌘	×	◊	˘	Δ	↺	№	-	-	-	-	-	-	-

Table 10.90: Glyphs in the AnonymousPro Symbol font

You can fill a complete line (with a 0.5-inch space at left and right) with a given character using the command `\dingline`, where the argument indicates the slot of the desired character. For filling parts of a line, use the command `\dingfill`. This command works similar to L^AT_EX's `\dotfill` command but uses the specified glyph instead of dots.

10-13-3

```

%< %< %< %< %< %< %< %< %< %<
⇒ ⇒ ⇒ some text ⇒ ⇒ some more ✖ ✖
\usepackage{pifont}
\dingline{"22} \par\medskip
\noindent\dingfill{"E9} some text
\dingfill{"EB} some more \dingfill{"36}

```

Besides providing direct support for the Zapf Dingbats font, the `pifont` package includes a general mechanism for coping with any Pi font that conforms to the NFSS classification `U/family/m/n`.

To access individual glyphs from such a Pi font, use the `\Pisymbol` command, which takes the *family* name as its first argument and the glyph position in the font as its second argument. For example, using this command one can readily access the Macintosh keyboard symbols from the Anonymous Pro Symbol font, shown in Table 10.90. All you need to know is the NFSS family name and the glyph position in the font. In fact, `\ding` (discussed earlier) is simply an abbreviation for `\Pisymbol` with the first argument set to `pzd`.

Accessing individual glyphs from a Pi font

You can also make itemized lists using `Pilist` or enumerated lists using the `Piautolist` environments as follows:

10-13-4

```

🍏 The Cmd key is ⌘.
🍏 The Alt key is ˘.
★ The first item.
★ The second.
★ The third.
\usepackage{pifont}
\begin{Pilist}{AnonymousPro}{1}
\item The Cmd key is \Pisymbol{AnonymousPro}{"22}.
\item The Alt key is \Pisymbol{AnonymousPro}{"13}.
\end{Pilist}
\begin{Piautolist}{pzd}{"4B}
\item The first item. \item The second.
\item The third.
\end{Piautolist}

```

The `\dingline` and `\dingfill` commands are also merely abbreviations for the more general commands `\Piline` and `\Pifill`, as shown below. The example reveals curious gaps in the last line. They are due to `\Piline` and `\Pifill`

	0	1	2	3	4	5	6	7	8	9	A	B	C	D	E	F

Table 10.92: Glyphs in the MarVoSym font (mvs)

however, you want the upright integrals, it is best to explicitly signal that intention by adding the option `integrals` because that allows the package to cooperate properly with `amsmath` or `mathtools` (see Section 11.4.6 on page 168).

10.13.3 marvosym — Interface to the MarVoSym font

The MarVoSym font designed by Martin Vogel is another Pi font containing symbols from various areas including quite uncommon ones, such as laundry signs (in case you are doing your own laundry lists ☺), astronomy and astrology symbols, and many others. In 2015 Martin wrote in his blog that he thinks the font is no longer needed as most characters are by now in Unicode fonts, but it is still quite popular in the L^AT_EX world, because the glyphs are well done and not easy to obtain otherwise.

The L^AT_EX support package `marvosym` was written by Thomas Henlich, who also converted the font from TrueType format to Type 1. His package defines command names for all symbols, some of which are listed in the next example; the full set is given in `marvodoc.pdf` accompanying the distribution.

```
\usepackage{marvosym}
\Large \AtForty\ \Bicycle\ \Cancer\ \Coffeecup\ \ComputerMouse\
\FEMALE\ \Faxmachine\ \Female\ \Fixedbearing\ \Football\
\ForwardToIndex\ \Frowny\ \IroningII\ \Keyboard\ \Lineload\
\Mobilefone\ \RewindToStart\ \Smiley\ \Virgo\ \Yinyang
```

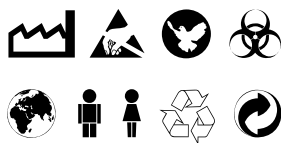

10-13-7

As with other Pi fonts, one can also access the symbols directly by using the

10.13.4 adforn — Adding ornaments to your document

A more recent addition to the symbol fonts for use with L^AT_EX is the Ornaments ADF font designed by Hirwen Harendal. The ornaments made available by this font are shown in Table 10.93. (Ornaments is the French spelling in case you are wondering.)

L^AT_EX support is provided through the package adforn by Clea F. Rees, which defines the command \adforn to access symbols by *slot-number* (which is yet another application of \Pisymbol from the pifont package, this time using the family name OrnamentsADF). In addition to the numerical interface each ornament is also available through an individual L^AT_EX command; e.g., \adfflowerleft and \adforn{20} would both produce ✂. Clearly the longer command names have the advantage that you can easily guess what they represent, but you have to look them up in the package documentation, while the slot numbers are readily available from Table 10.93.

☯ In this example we start most paragraphs with an ornament instead of an indentation.

But we do not always use the same one—most of the time we use a solid leaf, shown next.

☯ Also note the fancy page number below, set up with the help of fancyhdr.

≡ 6 ≡

```
\usepackage{fancyhdr,adforn}
\pagestyle{fancy} \fancyhf{} \renewcommand\headrulewidth{0pt}
\fancyfoot[C]{\adfdoubleflourishleft\ \thepage\
\adfdoubleflourishright}
\newcommand\paraA{\par\noindent\adfhangingleflatleafright\ }
\newcommand\paraB{\par\noindent\adfflatleafsolidright \ }
\paraA In this example we start most paragraphs with an
ornament instead of an indentation. \par But we do not
always use the same one---most of the time we use a solid
leaf, shown next. \paraB Also note the fancy page number
below, set up with the help of \texttt{fancyhdr}.
```

Table 10.94: Glyphs in the Fourier Ornaments font (futs)

10.13.5 fourier-orns — GUTenberg-Fourier’s ornaments

The Fourier Ornaments font, designed by Michel Bovani, is part of the Fourier-GUTenberg setup, but it is also available on its own through the `fourier-orns` package. The available glyphs are shown in Table 10.94. The package defines names, for each symbol, e.g., `\grimace`, `\lefthand`, or `\aldine` (☹, ☹, ☹), but of course, you can alternatively access them directly through the `pifont` package using the family name `futs`, as we show below.

The interesting pilcrow symbols in slots "33 to "38 are accessible through the commands `\oldpilcrowone`, `\oldpilcrowtwo`, ..., `\oldpilcrowsix` after loading the package; below we access them by slot number instead.¹ If you use them in your text, you have to make sure that you choose in each case the one with the appropriate length based on the position in the paragraph — the tail takes up no space and thus sticks into the margin if it gets too close.

☹All the world’s a stage, and all the men and women merely players. ☹They have their exits and their entrances; ☹And one man in his time plays many parts.

(*As You Like It*, Act 2, Scene 7)

```
\usepackage{color,pifont}
\newcommand{\pilcrow[1]
  {\textcolor{blue}{\Pisymbol{futs}{"3#1}}\ignorespaces}
\noindent\pilcrow{5} All the world’s a stage, and all the men
and women merely players. \pilcrow{7} They have their exits
and their entrances; \pilcrow{8} And one man in his time
plays many parts.\ (\emph{As You Like It}, Act 2, Scene 7))
```

10-13-10

10.13.6 Web-O-Mints — Another collection of ornaments and borders

The Web-O-Mints font, designed by George Ryan, provides a number of typographical decorations inspired by historical sources.² Basic L^AT_EX support in the form of mapping and font definition files has been provided by Maurizio Loreti. Due to the font license, the font and the L^AT_EX support files have to be manually installed using `getnonfreefonts` (at least with T_EX Live).

¹The slot positions differ in different versions of the font, so you may have to adjust the example.

²See page 99 on the historical Fell types that also provide historical ornaments.

Table 10.95: Glyphs in the webomints font (webo)

The example below defines a few commands to access the font, which has the family name `webo`. The `\webosym` command expects slot numbers that we can read off Table 10.95, whereas the second argument of `\webo` expects ASCII characters and simply draws the glyphs that are in their slot position (you may have to guess those or look them up in a font table of a text font).

```
\newcommand\webofamily{\usefont{U}{webo}{m}{n}}
\newcommand\webo[2]{\fontsize{#1}{#1}\webofamily #2}
\newcommand\webosym[1]{\webofamily\symbol{#1}}

\webo{12pt}{IJLK} \[5pt]
\webo{3ex}{pq} \webo{20pt}{ced} \webo{3ex}{UnoV} \[5pt]
\webo{13pt}{rst} \webo{13pt}{RSTP} \webo{13pt}{uvw} \[10pt]
Text \webosym{"32} mixed \webosym{"37} with
\webosym{"6D} ornaments \webosym{"7A}
```

10-13-11

There is also a nonstandard NFSS series `x1` defined that produces 20% larger glyphs.

10.13.7 fontawesome5 — Accessing Font Awesome icons

Font Awesome in version 5 is a collection of more than 5000 icons out of which roughly 1500 are available under a free license.

The icons have been packaged for use with all \LaTeX engines by Marcel Krüger. The support package is `fontawesome5`, which defines command names for every glyph. The naming convention is to take the glyph name,¹ convert it to CamelCase, and prefix it with `\fa`. For example, the icon `map-marker` would be accessed as `\faMapMarker`, generating 📍. Alternatively, you can use `\faIcon`, which expects the official icon names as its argument, i.e., `\faIcon{map-marker}` for the map marker symbol. A number of icons also have alternative versions (names that end in `-alt`). They can be accessed by using the star form of the base command; e.g., `\faMapMarker*` gives 📍.

¹The names can be found on the Web (see <https://www.fontawesome.com>) or in the documentation of the `fontawesome5` package.

Table 10.97: Glyphs in fontawesomefree0 regular

All free icons are available in **solid** style, with a number of them also in **regular** (which is far less dark), for example, all the different smiley variants. The style can be changed by specifying it in an optional argument to the command; e.g., `\faAngry` gives ☹, while `\faAngry[regular]` gets you 😞. It is also possible to change the default style from solid to regular with the command `\faStyle{regular}`.

Unicode engines

If you own the commercial Pro version of the font (which works only with Unicode engines), then there is also a **light** style, which can be accessed in the same way. To enable the Pro font use the package option `pro`.

Table 10.99: Glyphs in fontawesomefree1 regular

When using pdf_T_EX, the 1500 icons need to be distributed over different fonts (as each Type 1 font can contain only up to 256 glyphs). The family names are then fontawesomefree0 to ..free3 for ordinary icons and fontawesomebrands0 and ..brands1 for icons representing brands. The whole set is shown in Tables 10.96 to 10.103 on pages 121-124.

All brand icons are trademarks of their respective owners, and it is requested to use these brand logos only to represent the company, product, or service to which they refer but not for other purposes.

Most of the icons have roughly the same width, but this is not always the case. If you prefer to have them all occupying the same space, you can load the package

Table 10.104: Brand logos in fontawesomebrands1

10.13.8 tipa — International Phonetic Alphabet symbols

The TIPA bundle [52] developed by FUKUI Rei consists of a set of fonts and a corresponding package to enable typesetting of phonetic symbols with L^AT_EX. TIPA contains all the symbols, including diacritics, defined in the 1979, 1989, 1993, and 1996 versions of the International Phonetic Alphabet (IPA). Besides IPA symbols, TIPA contains symbols that are useful for other areas of phonetics and linguistics, e.g.:

- Symbols used in American phonetics, for example, æ , ɛ , ɔ , and λ ;
- Symbols used in the historical study of Indo-European languages, such as ɸ , p , h , z , ɸ , ɸ , and accents such as á and é ;
- Symbols used in the phonetic description of languages in East Asia, such as ɿ , ɿ , ɿ , ɿ (needs option `extra`);
- Diacritics used in *extIPA Symbols for Disordered Speech* and *VoQS (Voice Quality Symbols)*, for example, ̥ , ̦ , and ̧ (needs option `extra`).

The IPA symbols are encoded in the standard L^AT_EX encoding T3, for which the package `tipa` provides additional support macros. The encoding is available for the font families Computer Modern Roman, Sans, and Typewriter (based on the METAFONT designs for Computer Modern by Donald Knuth), as well as for older implementations of Times Roman and Helvetica; see below.

Strictly speaking, T3 is not a proper L^AT_EX text encoding, as it does not contain the visible ASCII characters in their standard positions. However, one can take the position that phonetic symbols form a language of their own, and for this language, the TIPA system provides a highly optimized input interface in which digits and uppercase letters serve as convenient shortcuts (see Table 10.105 on the next page) to input common phonetic symbols within the argument of `\text{tipa}` or the environment `IPA`. All phonetic symbols are also available in long form; for example, to produce a ə one can use `\text{textscha}`. The following example shows the TIPA system in a Times and Helvetica environment. Unfortunately, `tipa` offers direct support only for the old font

<i>input</i>	:	;	"		0	1	2	3	4	5	6	7	8	9
TIPA	:	˙	˘		u	i	Λ	3	u	e	D	γ	θ	ə
<i>input</i>	@	A	B	C	D	E	F	G	H	I	J	K	L	M
TIPA	ə	ɑ	β	ε	ð	ε	ϕ	γ	fi	ɪ	j	ʁ	ʌ	ɱ
<i>input</i>	N	O	P	Q	R	S	T	U	V	W	X	Y	Z	
TIPA	ŋ	ɔ	ʔ	ʃ	r	ʃ	θ	ʊ	ʊ	ʊ	χ	ʏ	ʒ	

Table 10.105: TIPA shortcut characters

family names `ptm` and `phv`. Thus, to use it with the modern T_EX Gyre fonts *Termes* and *Heros*, we have to explicitly substitute the old family names in T3 encoding.

In linguistics, fəʊˈnɛtɪk transcriptions are usually shown in square brackets, e.g., phonetics [fəʊˈnɛtɪks].

```
\usepackage{tgtermes,tgheros,tipa}
\DeclareFontFamilySubstitution{T3}{qtm}{ptm}
\DeclareFontFamilySubstitution{T3}{qhv}{phv}

In linguistics, f\textschwa\textupsilon\textprimstress
n\textepsilon t\i k transcriptions are usually shown in square
brackets, e.g., \textsf{phonetics \textipa{[f@U^nEtIks]}}.
```

10-13-14

*Redefined
math commands* 

TIPA defines `*`, `\;`, `\:`, `\!`, and `\|` as special macros with which to easily input phonetic symbols that do not have a shortcut input as explained above. In standard L^AT_EX all five are already defined for use in math mode, so loading *tipa* highjacks them for use by linguists. If that is not desirable, the option `safe` prevents these redefinitions. The long forms then have to be used—for example, the command `\textroundcap` instead of `\|c`. The following lines show a few more complicated examples with the output in Computer Modern Roman, Sans, and Typewriter:

ŋOöõ ŋOâ?ã
A) dɔg, B) kæt, C) maʊs
*k̥mtóm *bhrâtēr

```
\usepackage{tipa}

\begin{IPA} \textrm{N\!o'\{~*o}\~o \r*N\!o^~aP\~a} \par
\textsf{\*A} dOg, \*B) k\ae{}t, \*C) maUs} \par
\texttt{\*|c{k}\r*mt\~om *bhr\~=at\=er} \end{IPA}
```

10-13-15

If loaded with the option `tone`, TIPA provides a `\tone` command to produce “tone letters”. The command takes one argument consisting of a string of numbers denoting pitch levels, 1 being the lowest and 5 the highest. Within this range, any combination is allowed, and there is no limit on the length of the combination, as exemplified in the last line of the next example, which otherwise shows the usage of `\tone` to display the four tones of Chinese.

ᵀma (mother) ᵁma (horse)
ᵀma (hemp) ᵁma (scold)
ᵀᵀᵀ

```
\usepackage[tone]{tipa}

\tone{55}ma (mother) \tone{214}ma (horse) \par
\tone{35}ma (hemp) \tone{51}ma (scold) \par \tone{153325413}
```

10-13-16

The above examples merely scrape the surface of the possibilities offered by TIPA. To explore it in detail consult the *tipaman* manual, which is part of the TIPA distribution.

CHAPTER 11

Higher Mathematics

11.1 Introduction to amsmath and mathtools	128
11.2 Display and alignment structures for equations	131
11.3 Matrix-like environments	153
11.4 Compound structures and decorations	163
11.5 Variable symbol commands	180
11.6 Words in mathematics	191
11.7 Fine-tuning the mathematical layout	194
11.8 Symbols in formulas	208

Basic \LaTeX offers excellent mathematical typesetting capabilities for straightforward documents. However, when complex displayed equations or more advanced mathematical constructs are heavily used, something more is needed. Although it is possible to define new commands or environments to ease the burden of typing in formulas, this is not the best solution. In the early nineties the American Mathematical Society (AMS) provided a major package, `amsmath`, which made the preparation of mathematical documents much less time-consuming and more consistent.¹ It forms the core of a collection of packages known as $\mathcal{A}\mathcal{M}\mathcal{S}\text{-}\text{\LaTeX}$ [5] and is the major subject of this chapter. A useful book by George Grätzer [59] also covers these packages in detail.

This chapter describes briefly, and provides examples of, a substantial number of the many features of these packages as well as a few closely related packages; it also gives a few pointers to other relevant packages. In addition, it provides some essential background on mathematical typesetting with \TeX . Thus, it covers some of standard \LaTeX 's features for mathematical typesetting and layout and contains some general hints on how to typeset mathematical formulas, though these are not the main aims of this chapter. It is also definitely not a comprehensive manual of good practice for typesetting mathematics with \LaTeX . Indeed, many of the examples are

¹This package has its foundations in the macro-level extensions to \TeX known as $\mathcal{A}\mathcal{M}\mathcal{S}\text{-}\text{\TeX}$.

offered purely for illustration purposes and, therefore, present neither good design nor good mathematics nor necessarily good L^AT_EX coding.

Advice on how to typeset mathematics according to late 20th century U.S. practice can be found in Ellen Swanson's *Math into Type* [187]. Many details concerning how to implement this advice using T_EX or, equally, standard L^AT_EX appear in Chapters 16–18 of Donald Knuth's *The T_EXbook* [84].

To use the majority of the material described in this chapter, you need to load at least the `amsmath` or `mathtools` package in the preamble of your document. If other packages are needed, they are clearly marked in the examples. Detailed installation and usage documentation is included with the individual packages.

11.1 Introduction to `amsmath` and `mathtools`

The $\mathcal{A}\mathcal{M}\mathcal{S}$ -L^AT_EX project commenced in 1987, and three years later $\mathcal{A}\mathcal{M}\mathcal{S}$ -L^AT_EX version 1.0 was released. This was the original conversion to L^AT_EX of the mathematical capabilities in Michael Spivak's $\mathcal{A}\mathcal{M}\mathcal{S}$ -T_EX by Frank Mittelbach and Rainer Schöpf, working as consultants to the American Mathematical Society, with assistance from Michael Downes (1958–2003) of the AMS technical staff. In 1994, further work was done with David Jones. This work was coordinated by Michael Downes, and the packages have throughout been supported and much enhanced under his direction and the patronage of the AMS.¹ Initially $\mathcal{A}\mathcal{M}\mathcal{S}$ -L^AT_EX was a separate format, which is the reason for the separate name, but at some point, when computers got faster and faster, the functionality was moved to the package `amsmath`, which could be loaded into standard L^AT_EX, and the support for a separate format was dropped. Thus, these days speaking of $\mathcal{A}\mathcal{M}\mathcal{S}$ -L^AT_EX simply refers to `amsmath` or the AMS document classes that evolved from that project.

In 2016 the AMS passed maintenance and control of `amsmath` and some of its accompanying packages back to the L^AT_EX Project Team, because its math capabilities are a core functionality of L^AT_EX.²

*Thanks to
a great guy!*

Michael Downes (1958–2003) would have been the author of this chapter when we wrote the second edition of this book had he not died in spring 2003. Much of the chapter is based on the documentation he prepared for $\mathcal{A}\mathcal{M}\mathcal{S}$ -L^AT_EX; thus, what you are reading is a particular and heartfelt tribute by its current author to the life and work of a dear friend and colleague with whom we shared many coding adventures in the uncharted backwaters of T_EX.

*Available package
options*

A few options are recognized by the `amsmath` package. Most of these affect only detailed positioning of the “limits” on various types of mathematical operators (Section 11.4.4) or that of equation tags (Section 11.2.4).

¹Some material in this chapter is reprinted from the documentation that was distributed with $\mathcal{A}\mathcal{M}\mathcal{S}$ -L^AT_EX (with permission from the American Mathematical Society).

²However, the American Mathematical Society retained maintenance and support of the AMS fonts and the document classes `amsart`, `amsbook`, and `amsproc`; thus, any issue or inquiries concerning these classes or font packages have to be taken up with their technical stuff and not the L^AT_EX Project Team.

The following three options are often supplied as global document options, set on the `\documentclass` command. They are, however, also recognized when the `amsmath` package is loaded with the `\usepackage` command.

- `reqno` **(default)** Place equation numbers (tags) on the right.
- `leqno` Place equation numbers (tags) on the left.¹
- `fleqn` Position equations at a fixed indent from the left margin rather than centered in the text column.

For historical reasons some components of the `amsmath` package exist as separate packages so that they can be loaded on their own — a feature that was essential when computer memory was tight and just loading a large package like `amsmath` was taking considerable time. These days the advice is to always load `amsmath` and not try to determine what is needed and what is not.

*Available
subpackages*

- `amsofn` Provides `\DeclareMathOperator` for defining new operator names such as `\Ker` and `\esssup`.
- `amstext` Provides the `\text` command for typesetting a fragment of text in the correct type size.

The principal documentation for these two packages is the *User's Guide for the amsmath Package (Version 2.1)* [5], which is part of the \LaTeX distribution.

The following packages, providing functionality additional to that in `amsmath`, must be loaded explicitly; they are listed here for completeness.

Extension packages

- `amscd` Defines some commands for easing the generation of commutative diagrams by introducing the `CD` environment (see Section 11.3.5 on page 159). There is no support for diagonal arrows.
- `amsthm` Provides a method to declare theorem-like structures and offers a `proof` environment. It is discussed in Section 4.1.4 on page 281.
- `amsxtra` Provides certain odds and ends that are needed for historical compatibility, such as `\fracwithdelims`, `\accentedsymbol`, and commands for placing accents as superscripts.
- `upref` Makes `\ref` print cross-reference numbers in an upright/roman font regardless of context.

The `amsmath` package is very comprehensive and provides most of what is needed when attempting serious mathematical typesetting. It is, however, rather static; i.e., it has not seen many additions (or fixes) since its initial development in the nineties. Because of this, several smaller packages, some of which we discuss in this chapter, have been developed to add one or the other missing feature. In addition, there is

*mathtools — A
drop-in replacement
for amsmath*

¹When using one of the AMS document classes, the default is `leqno`.

also the `mathtools` package by Morten Høgholm now maintained by Lars Madsen that has been explicitly developed to offer a replacement for `amsmath`. It provides all features of `amsmath` (including the support for all of its package options), augments it with several new features, and fixes a number of known bugs in `amsmath`. We give examples of its extended functionality in the appropriate places, and if you intend to use any of this, you should load `mathtools` in place of `amsmath`.

The $\mathcal{A}\mathcal{M}\mathcal{S}$ - \LaTeX document classes

As already mentioned, the three document classes `amsart`, `amsproc`, and `amsbook` from the original $\mathcal{A}\mathcal{M}\mathcal{S}$ - \LaTeX collection are still maintained by the American Mathematical Society. They correspond to \LaTeX 's `article`, `proc`, and `book`, respectively, and are designed to be used in the preparation of manuscripts for submission to the AMS. However, given that they are part of every \LaTeX distribution, nothing prohibits their use for other purposes. In fact, they are often used as the base class for other journals instead of the standard \LaTeX classes.

With these class files the `amsmath` package is automatically loaded so that you can start your document simply with `\documentclass{amsart}`. These classes are not covered in this book because they provide an interface similar to that provided by the \LaTeX standard classes; refer to [4] for details of their use.

The AMSfonts collection

Some of the material in this chapter refers to another collection of packages from the American Mathematical Society, namely, the `AMSfonts` distribution. These packages, listed below, set up various fonts and commands for use in mathematical formulas.

`amsfonts` Defines the `\mathfrak` and `\mathbb` commands and sets up the fonts `msam` (extra math symbols A), `msbm` (extra math symbols B and blackboard bold), `eufm` (Euler Fraktur), extra sizes of `cmmib` (bold math italic and bold lowercase Greek), and `cmbsty` (bold math symbols and bold script) for use in mathematics.

`amssymb` Defines the names of the mathematical symbols available with the `AMSfonts` collection. These commands are discussed in Section 11.8. The package automatically loads the `amsfonts` package.

`eufrak` Sets up the fonts for the Euler Fraktur letters (`\mathfrak`), as discussed in Section 12.3.3. This alphabet is also available from the `amsfonts` package.

`eucal` Makes `\mathcal` use the Euler script instead of the usual Computer Modern script letters; see Section 12.3.3 for details.

The above packages and fonts are maintained by the American Mathematical Society, and the principal piece of documentation for both is the *User's Guide to AMSFonts Version 2.2d* [2]. However, the distribution is now in version 3, while the documentation is still describing version 2.2d. Though most of it is still accurate and relevant, there is one area where the guide talks about METAFONT (bitmapped) versus Type 1 (outline) fonts that you need to ignore. These days only the Type 1 fonts are distributed, so this part is giving incorrect advice. In particular, the `psamsfonts` option described there should no longer be used, because it is no longer recognized by all of the packages and produces either a warning or an error.

Documentation is somewhat dated, but still relevant

A few important warnings

Many of the commands described in this chapter have been fragile in the past and needed to be `\protected` in moving arguments (see Appendix B.1 on page 715). Thus, when strange error messages appear, a missing `\protect` is a likely cause. A part of the maintenance work of the L^AT_EX Project Team is to make all of them robust so that over time this issue should vanish.

 *Watch out for fragile commands*

It is never a good idea to use shortcut codes for L^AT_EX environments. With the `amsmath` display environments described in this chapter, such shortcuts are always disastrous — do not do it! For closely related reasons, you will also find that verbatim material cannot be used within these environments. Here are some examples of declarations for disaster:

 *Do not abbreviate environments*

```
\newenvironment{mlt}{\begin{multline}}{\end{multline}}
\newcommand\bga{\begin{gather}} \newcommand\ega{\end{gather}}
```

Both produce errors of the form “`\begin{...}` ended by ...”. However, you can define synonyms and variant forms of these environments as follows:

```
\newenvironment{mlt}{\multline}\endmultline}
\newenvironment{longgather}{\allowdisplaybreaks\gather}{\endgather}
```

Note that these must have the command form of an existing environment as the last command in the “begin-code”, and the corresponding `\end...` command as the first thing in the “end-code”. See also Section A.1.3 for more details.

11.2 Display and alignment structures for equations

The `amsmath` package defines several environments for creating displayed mathematics. These cover single- and multiple-line displays with single or multiple alignment points and various options for numbering equations within displays.

Throughout this section the term “equation” is used in a very particular way: to refer to a *logically* distinct part of a mathematical display that is frequently numbered for reference purposes and is also labeled (commonly by its number in parentheses). Such labels are often called *tags*.

11-2-1

$$(1) \quad (a+b)^2 = a^2 + 2ab + b^2$$

$$\sin^2 \eta + \cos^2 \eta = 1$$

```
\usepackage[leqno]{amsmath}
\begin{equation} (a+b)^2 = a^2+2ab+b^2 \end{equation}
\[ \sin^2\eta+\cos^2\eta = 1 \]
```

None of the math environments allow empty lines in their body. If you wish to structure your input source, use lines that are empty except for a %-sign at the beginning.

The complete list of all the display environments from `amsmath` and `mathtools` available for mathematical typesetting is given in Table 11.1 on the next page; the majority of these environments are covered in this section, along with examples of

Math Display Environments		Effect
equation	equation*	One line, one equation (equation* corresponds to <code>\[... \]</code>)
multline	multline*	One unaligned multiple-line equation, one equation number
gather	gather*	Several equations without alignment
align	align*	Several equations with multiple alignments
flalign	flalign*	Several equations: horizontally spread form of align
alignat	alignat*	Several equations: no extra spacing
split		A simple alignment within a multiple-line equation
gathered		A “mini-page” with unaligned equations
aligned	alignedat	A “mini-page” with multiple alignments (with/without spacing)
Environments added by mathtools		
lgathered	rgathered	A “mini-page” with left or right equations
multlined		A “mini-page” with a multline inside

Table 11.1: Display environments in the amsmath/mathtools packages

their use. Where appropriate they have starred forms in which there is no numbering or tagging.

To position the mathematics at a fixed indent from the left margin, rather than centered in the text column, use the option `fleqn`. You then normally need to set the size of the indent in the preamble. It is the value of the rubber length `\mathindent`, which gets its default value from the indentation of a first-level list — which is probably not the value you want! Observe the differences between the next example and the previous example. In this particular case, use of the `reqno` option is redundant (as it is the default), but it forces the equation number to the right side regardless of what the document class specifies.

$(a + b)^2 = a^2 + 2ab + b^2$	(1)	<pre>\usepackage[fleqn,reqno]{amsmath} \setlength\mathindent{1pc minus 1pc} \begin{equation} (a+b)^2 = a^2+2ab+b^2 \end{equation} \[\sin^2\eta+\cos^2\eta = 1 \]</pre>	11-2-2
$\sin^2 \eta + \cos^2 \eta = 1$			

If you use a minus component in the value for `\mathindent` as we did in the previous example, very wide formulas can protrude into that indentation if they do not otherwise fit into the available space.

As later examples show, as in standard \LaTeX , `&` and `\\` are used for column and line separation within displayed alignments. The details of their usage change in the `amsmath` environments, however (see the next section).

11.2.1 Comparison of amsmath/mathtools with standard \LaTeX

Some of the multiple-line display environments allow you to align parts of the formula. In contrast to the original \LaTeX environments `eqnarray` and `eqnarray*`, the structures implemented by the `amsmath` package use a slightly different and

more straightforward method for marking the alignment points. Standard \LaTeX 's `eqnarray*` is similar to an `array` environment with `{rcl}` as the preamble and, therefore, requires two ampersand characters indicating the two alignment points. In the equivalent `amsmath` structures there is only a single alignment point (similar to a `{rl}` preamble), so only a single ampersand character should be used, placed to the left of the symbol (usually a relation) that should be aligned.

The `amsmath` structures give fixed spacing at the alignment points, whereas the `eqnarray` environment produces extra space depending on the parameter settings for `array`. The difference can be seen clearly in the next example, where the same equation is typeset using the `equation`, `align`, and `eqnarray` environments; the spaces in the `eqnarray` environment come out too wide for conventional standards of mathematical typesetting.

11-2-3

$x^2 + y^2 = z^2$	(1)	<code>\usepackage{amsmath}</code>
$x^2 + y^2 = z^2$	(2)	<code>\begin{equation}</code>
$x^3 + y^3 < z^3$	(3)	<code>x^2 + y^2 = z^2</code>
$x^2 + y^2 = z^2$	(4)	<code>\end{equation}</code>
$x^3 + y^3 < z^3$	(5)	<code>\begin{align}</code>
		<code>x^2 + y^2 &= z^2 \ \ x^3 + y^3 &< z^3</code>
		<code>\end{align}</code>
		<code>\begin{eqnarray}</code>
		<code>x^2 + y^2 &=& z^2 \ \ x^3 + y^3 &<& z^3</code>
		<code>\end{eqnarray}</code>

As in standard \LaTeX , lines in an `amsmath` display are marked with `\\` (or the end of the environment). Because line breaking in a mathematical display usually requires a thorough understanding of the structure of the formula, it is commonly considered to be beyond today's software capabilities. However, one of the last bigger projects undertaken by Michael Downes (1958–2003) precisely tackled this problem; it resulted in the `breqn` package (see Section 11.2.12 on page 146 for an overview).

Unlike `eqnarray`, the `amsmath` environments do not, by default, allow page breaks between lines (see Section 11.2.11). Furthermore, they move the equation tag out of the way if it would otherwise overprint the formula.

Another difference concerns the use of `\\[dimension]` or `*` within mathematical display environments. With `amsmath`, there must be no space between the `\\` and the `[` or the `*`; otherwise, the optional argument or star will not be recognized. The reason is that brackets and stars are very common in mathematical formulas, so this restriction avoids the annoyance of having a genuine bracket belonging to the formula be mistaken for the start of the optional argument.

 Space after
`\\` not ignored

11.2.2 A single equation on one line

The `equation` environment produces a single equation with an automatically generated number or tag placed on the extreme left or right according to the option in use (see Section 11.2.13); `equation*` does the same but omits a tag.¹

¹ Standard \LaTeX also has `equation`, but not `equation*`, because the latter is similar to the standard displayed math environment.

Note that the presence of the tag does not affect the positioning of the contents. If there is not enough room for it on the one line, the tag is shifted up or down: to the previous line when equation numbers are on the left, and to the next line when numbers are on the right.

	$n^2 + m^2 = k^2$	<pre>\usepackage[leqno]{amsmath} \begin{equation*} n^2 + m^2 = k^2 \end{equation*} \begin{equation} n^p + m^p \neq k^p \quad \text{p} > 2 \end{equation}</pre>
(1)	$n^p + m^p \neq k^p \quad p > 2$	

11-2-4

11.2.3 A single equation on several lines: no alignment

The `multline` environment is a variation of the `equation` environment used only for equations that do not fit on a single line. In this environment `\\` must be used to mark the line breaks, because they are not found automatically.

The first line of a `multline` is aligned on an indentation from the left margin and the last line on the same indentation from the right margin.¹ The size of this indentation is the value of the length `\multlinegap`; thus, it can be changed using \LaTeX 's `\setlength` and `\addtolength` commands.

If a `multline` contains more than two lines, each line other than the first and last is centered individually within the display width (unless the option `fleqn` is used). It is, however, possible to force a single line to the left or the right by adding either `\shoveleft` or `\shoveright` within that line.

A `multline` environment is a single (logical) equation and thus has only a single tag, the `multline*` having none; thus, none of the individual lines can be changed by the use of `\tag` or `\notag`. The tag, if present, is placed flush right on the last line with the default `reqno` option or flush left on the first line when the `leqno` option is used.

First line of a multiline		<pre>\usepackage{amsmath} \begin{multline} \text{First line of a multiline} \\ \text{Centered Middle line} \\ \text{A right Middle} \\ \text{Another centered Middle} \\ \text{Yet another centered Middle} \\ \text{A left Middle} \\ \text{Last line of the multiline} \end{multline}</pre>
	(1)	

11-2-5

The next example shows the effect of `\multlinegap`. In the first setting, the “*dy*”s line up and make it appear that a tag is missing from the first line of the equation.

¹Never use `multline` for a single-line equation because the effect is unpredictable.

When the parameter is set to zero, the space on the left of the second line does not change because of the tag, while the first line is pushed over to the left margin, thus making it clear that this is only one equation.

11-2-6

$$\sum_{t \in \mathbf{T}} \int_a^t \left\{ \int_a^t f(t-x)^2 g(y)^2 dx \right\} dy$$

$$= \sum_{t \notin \mathbf{T}} \int_t^a \left\{ g(y)^2 \int_t^a f(x)^2 dx \right\} dy \quad (2)$$

$$\sum_{t \in \mathbf{T}} \int_a^t \left\{ \int_a^t f(t-x)^2 g(y)^2 dx \right\} dy$$

$$= \sum_{t \notin \mathbf{T}} \int_t^a \left\{ g(y)^2 \int_t^a f(x)^2 dx \right\} dy \quad (2)$$

```
\usepackage{amsmath}
\begin{multline} \tag{2}
\sum_{t \in \mathbf{T}} \int_a^t \int_a^t f(t-x)^2 g(y)^2 dx dy \\
= \sum_{t \notin \mathbf{T}} \int_t^a g(y)^2 \int_t^a f(x)^2 dx dy
\end{multline}
\setlength{\multlinegap}{0pt}
\begin{multline} \tag{2}
\sum_{t \in \mathbf{T}} \int_a^t \int_a^t f(t-x)^2 g(y)^2 dx dy \\
= \sum_{t \notin \mathbf{T}} \int_t^a g(y)^2 \int_t^a f(x)^2 dx dy
\end{multline}
```

11.2.4 A single equation on several lines: with alignment

When a simple alignment is needed within a single multiple-line equation, the `split` environment is almost always the best choice. It uses a single ampersand (&) on each line to mark the alignment point.

11-2-7

$$(a+b)^4 = (a+b)^2(a+b)^2$$

$$= (a^2 + 2ab + b^2)(a^2 + 2ab + b^2) \quad (1)$$

$$= a^4 + 4a^3b + 6a^2b^2 + 4ab^3 + b^4$$

```
\usepackage{amsmath}
\begin{equation}
\begin{split}
(a+b)^4 \\
&= (a+b)^2 (a+b)^2 \\
&= (a^2 + 2ab + b^2) \\
&\quad (a^2 + 2ab + b^2) \\
&= a^4 + 4a^3b + 6a^2b^2 + 4ab^3 + b^4
\end{split}
\end{equation}
```

Because it is always used as the content of a single (logical) equation, a `split` does not itself produce any numbering tag, and hence there is no starred variant. If needed, the outer display environment provides any needed tags.

Apart from commands such as `\label` or `\notag` that produce no visible material, a `split` structure should normally constitute the entire body of the equation being split. It can consist of either a whole equation or `equation*` environment or one whole line of a `gather` or `gather*` environment; see Section 11.2.5.

When the `centertags` option is in effect (the default), the tag (and any other material in the equation outside the `split`) is centered vertically on the total height of the material from the `split` environment. When the `tbtags` option is specified, the tag is aligned with the last line of the split when the tag is on the right, and with the first line of the split when the tag is on the left.

$ \begin{aligned} (a+b)^3 &= (a+b)(a+b)^2 \\ &= (a+b)(a^2 + 2ab + b^2) \\ &= a^3 + 3a^2b + 3ab^2 + b^3 \end{aligned} \tag{1} $	<pre> \usepackage[tbtags]{amsmath} \begin{equation} \begin{split} (a+b)^3 &= (a+b)(a+b)^2 \\ &= (a+b)(a^2 + 2ab + b^2) \\ &= a^3 + 3a^2b + 3ab^2 + b^3 \end{split} \end{equation} </pre>	11-2-8
---	--	--------

In the next example the command `\phantom` is used to adjust the horizontal positioning. It is first used in the preamble to define an “invisible relation symbol” of width equal to that of its argument (in this case, `=`). Within the example it is used to align certain lines by starting them with a “phantom or invisible subformula” (see Section 11.7.2 on page 197).

Ensure that + is interpreted as a binary symbol

The empty pair of braces, `{}`, is equivalent to `\mathord{}` and provides an invisible zero-width “letter” that is needed to achieve the correct spacing of `+ h` (without the `{}` it would look like this: `+h`).

```

\usepackage{amsmath}
\newcommand\relphantom[1]{\mathrel{\phantom{#1}}}
\newcommand\ve{\varepsilon} \newcommand\tve{t_{\varepsilon}}
\newcommand\vf{\varphi} \newcommand\yvf{y_{\varphi}}
\newcommand\bfe{\mathbf{E}}
\begin{equation}
\begin{split}
f_h, \ve(x, y)
&= \ve \bfe_{x, y} \int_0^{\tve} L_{x, \yvf(\ve u)} \vf(x) \, du \\
&= h \int L_{x, z} \vf(x) \rho_x(dz) \\
&\relphantom{=} {} + h \biggl[ \\
&\quad \frac{1}{\tve} \\
&\quad \biggl( \bfe_y \int_0^{\tve} L_{x, y^x(s)} \vf(x) \, ds \\
&\quad \quad - \ve \int L_{x, z} \vf(x) \rho_x(dz) \biggr) + \\
&\relphantom{=} \phantom{{}} + h \biggl[ \\
&\quad \frac{1}{\tve} \\
&\quad \biggl( \bfe_y \int_0^{\tve} L_{x, y^x(s)} \vf(x) \, ds \\
&\quad \quad - \bfe_{x, y} \int_0^{\tve} L_{x, \yvf(\ve s)} \\
&\quad \quad \quad \vf(x) \, ds \biggr) \biggr]
\end{split}
\end{equation}

```

Note that the equation number tag has been moved to the line below the displayed material. Although this does not seem to be a very wise decision, it is as far as the automated expertise built into the system at this stage can take us.

11-2-9

$$\begin{aligned}
 f_{h,\varepsilon}(x,y) &= \varepsilon \mathbf{E}_{x,y} \int_0^{t_\varepsilon} L_{x,y_\varphi(\varepsilon u)} \varphi(x) du \\
 &= h \int L_{x,z} \varphi(x) \rho_x(dz) \\
 &\quad + h \left[\frac{1}{t_\varepsilon} \left(\mathbf{E}_y \int_0^{t_\varepsilon} L_{x,y^x(s)} \varphi(x) ds - t_\varepsilon \int L_{x,z} \varphi(x) \rho_x(dz) \right) + \right. \\
 &\quad \left. \frac{1}{t_\varepsilon} \left(\mathbf{E}_y \int_0^{t_\varepsilon} L_{x,y^x(s)} \varphi(x) ds - \mathbf{E}_{x,y} \int_0^{t_\varepsilon} L_{x,y_\varphi(\varepsilon s)} \varphi(x) ds \right) \right] \quad (1)
 \end{aligned}$$

11.2.5 Equation groups without alignment

The `gather` environment is used to put two or more equations into a single display without alignment between the equations. Each equation is separately centered within the display width and has its individual number tag, if needed. Each line of a `gather` is a single (logical) equation.

11-2-10

$$\begin{aligned}
 (a+b)^2 &= a^2 + 2ab + b^2 & (1) \\
 (a+b) \cdot (a-b) &= a^2 - b^2 & (2)
 \end{aligned}$$

```

\usepackage{amsmath}
\begin{gather}
(a + b)^2 = a^2 + 2ab + b^2 \\
(a + b) \cdot (a - b) = a^2 - b^2
\end{gather}

```

Use `\notag` within the logical line to suppress the equation number for that line; or use `gather*` to suppress all equation numbers.

11-2-11

$$\begin{aligned}
 D(a,r) &\equiv \{z \in \mathbf{C} : |z - a| < r\} \\
 \text{seg}(a,r) &\equiv \{z \in \mathbf{C} : \Im z < \Im a, |z - a| < r\} & (1) \\
 C(E,\theta,r) &\equiv \bigcup_{e \in E} c(e,\theta,r) & (2)
 \end{aligned}$$

```

\usepackage{amsmath}
\begin{gather}
D(a,r) \equiv \{ z \in \mathbf{C} : \\
\quad \colon |z - a| < r \} \quad \notag \\
\operatorname{seg}(a,r) \equiv \\
\{ z \in \mathbf{C} \colon \\
\quad \Im z < \Im a, \ |z - a| < r \} \quad \notag \\
C(E,\theta,r) \equiv \\
\bigcup_{e \in E} c(e,\theta,r)
\end{gather}

```

11.2.6 Equation groups with simple alignment

The `align` environment should be used for two or more equations in a single display with vertical alignment. The simplest form uses a single ampersand (&) on each line to mark the alignment point (usually just before a Relation symbol).

$(a+b)^3 = (a+b)(a+b)^2$	(1)	<code>\usepackage{amsmath}</code>	
$= (a+b)(a^2 + 2ab + b^2)$	(2)	<code>\begin{align}</code>	
$= a^3 + 3a^2b + 3ab^2 + b^3$	(3)	$(a+b)^3 \quad \&= (a+b) (a+b)^2 \quad \backslash\backslash$	
		$\quad \&= (a+b)(a^2 + 2ab + b^2) \quad \backslash\backslash$	
		$\quad \&= a^3 + 3a^2b + 3ab^2 + b^3$	11-2-12
		<code>\end{align}</code>	
$x^2 + y^2 = 1$	(4)	<code>\begin{align}</code>	
$x = \sqrt{1-y^2}$	(5)	$x^2 + y^2 \quad \&= 1 \quad \backslash\backslash$	
		$x \quad \&= \sqrt{1-y^2}$	
		<code>\end{align}</code>	

11.2.7 Multiple alignments: `align`, `flalign`, and `alignat`

An `align` environment can include more than one alignment point. The layout contains as many column-pairs as necessary and is similar to an `array` with a preamble of the form `{r1r1...}` except that it does not change the spacing around the alignment points. If it consists of n such `r1` column-pairs, then the number of ampersands per line is $2n - 1$: one ampersand for alignment within each column-pair giving n ; and $n - 1$ ampersands to separate the column-pairs.

Within the `align` environment, the material is spread out evenly across the display width. All extra (or white) space within the line is distributed equally “between consecutive `r1` column-pairs” and the two display margins.

This example has two column-pairs.		<code>\usepackage{amsmath}</code>	
Compare $x^2 + y^2 = 1$	$x^3 + y^3 = 1$	(1)	<code>This example has two column-pairs.</code>
$x = \sqrt{1-y^2}$	$x = \sqrt[3]{1-y^3}$	(2)	<code>\begin{align} \quad \text{\text{Compare}} \quad</code>
			$x^2 + y^2 \quad \&= 1 \quad \&$
			$x^3 + y^3 \quad \&= 1 \quad \backslash\backslash$
			$x \quad \&= \sqrt{1-y^2} \quad \&$
			$x \quad \&= \sqrt[3]{1-y^3}$
			<code>\end{align}</code>
This example has three column-pairs.			11-2-13
$x = y$	$X = Y$	$a = b + c$	(3)
$x + x' = y + y'$	$X + X' = Y + Y'$	$a'b = c'b$	(4)
			<code>\begin{align}</code>
			$x \quad \&= y \quad \& X \quad \&= Y \quad \&$
			$a \quad \&= b+c \quad \backslash\backslash$
			$x + x' \quad \&= y + y' \quad \&$
			$X + X' \quad \&= Y + Y' \quad \& a'b \quad \&= c'b$
			<code>\end{align}</code>

In the variant `flalign` the layout is similar except that there is no space at the margins. As a result, in the next example, Equation (3) now fits on a single line (while in Equation (2) this was still not possible).

This example has two column-pairs.

Compare $x^2 + y^2 = 1$ $x^3 + y^3 = 1$ (1)

$$\begin{array}{ll} x = \sqrt{1 - y^2} & x = \sqrt[3]{1 - y^3} \\ & (2) \end{array}$$

11-2-14

This example has three column-pairs.

$$x = y \qquad X = Y \qquad a = b + c \quad (3)$$

$$x + x' = y + y' \quad X + X' = Y + Y' \quad a'b = c'b \quad (4)$$

```
\usepackage{amsmath}
```

This example has two column-pairs.

```
\begin{flalign} \text{Compare } & \\ x^2 + y^2 &= 1 & & \\ x^3 + y^3 &= 1 & & \\ x &= \sqrt{1-y^2} & & \\ x &= \sqrt[3]{1-y^3} & & \end{flalign}
```

\end{flalign}

This example has three column-pairs.

$$\begin{aligned} & \text{\texttt{\textbackslash begin\{flalign\}}} \\ & \end{aligned}$$
$$\begin{array}{rcl} x & \&= y & \& X \&= Y \& \\ a & \&= b+c & \backslash \backslash \\ x + x' & \&= y + y' & \& \\ X + X' & \&= Y + Y' & \& a'b \&= c'b \end{array}$$
$$\end{flalign}$$

In both cases the minimum space between column-pairs can be set by changing `\minalignsep`. Its default value is 10pt, but, misleadingly, it is *not* a length parameter. Thus, it must be changed by using `\renewcommand`. If we set it to zero for the first part of the example, Equation (2) gets squeezed onto a single line; if we set it to 15pt later, the label (3) gets forced onto a line by itself. Unfortunately, there is no such simple parametric method for controlling the spacing at the margins.

This example has two column-pairs.

Compare $x^2 + y^2 = 1$ $x^3 + y^3 = 1$ (1)

$$x = \sqrt{1 - y^2} \quad x = \sqrt[3]{1 - y^3} \quad (2)$$

11-2-15

This example has three column-pairs.

$$x = y \qquad X = Y \qquad a = b + c$$

$$\frac{d}{dt} \left(\frac{1}{\rho} \right) = - \frac{1}{\rho^2} \frac{d\rho}{dt} \quad (3)$$

$$x + x' = y + y' \quad X + X' = Y + Y' \quad a'b = c'b \quad (4)$$

```
\usepackage{amsmath}
```

This example has two column-pairs.

```
\renewcommand\minalignsep{0pt}
\begin{align} \text{\Compare } & \\ x^2 + y^2 &= 1 && & \\ x^3 + y^3 &= 1 && & \\ x &= \sqrt[3]{1-y^3} && & \\ x &= \sqrt[3]{1-y^3} && & \end{align}
```

$$\end{align}$$

This example has three column-pairs.

```
\renewcommand\minalignsep{15pt}
```

 $\begin{aligned}$

x	&= y	& X	&= Y	&
a	&= b+c			\\
x + x'	&= y + y'			&
X + X'	&= Y + Y'	& a'b	&= c'b	

\end{flalign}

Sometimes it is more convenient to explicitly specify all the horizontal spacing yourself within the formula. For this you can use an `alignat` environment. It differs from `align` in two ways: you have to specify the number of `rl` pairs as an argument to the environment and it does not add any spaces between the pairs, e.g.,

$$x \approx y \quad X \approx Y \quad a \approx b+c \quad \dots$$

As usual, equation numbers can be altered with `\tag` or suppressed with `\notag`.

The next example illustrates a very common use for `align`. Note the use of `\text` to produce normal text within the mathematical material. Do not forget to reset `\minalignsep` if you change it in this manner.

$x = y$ $x' = y'$ $x + x' = y + y'$	by hypothesis (1) by definition (2) by Axiom 1 (3)	<pre> \usepackage{amsmath} \renewcommand\minalignsep{30pt} \begin{align} x &= y && \text{by hypothesis} \\ x' &= y' && \text{by definition} \\ x + x' &= y + y' && \text{by Axiom 1} \end{align} \renewcommand\minalignsep{10pt} </pre>
-------------------------------------	--	---

11-2-16

11.2.8 Display environments as mini-pages

All the environments described so far produce material set to the full display width. A few of these environments have also been adapted to provide self-contained alignment structures, as if they were set as the only content of a `minipage` environment whose size, in both directions, is determined by its contents. You can think of them as subsidiary environments that can be used within any of the display environments discussed so far. (Below we use them inside `equation`.)

*mathtools additions
to amsmath*

The environment names are changed only slightly—to `aligned`, `gathered`, and `alignedat`—and when using `mathtools`, there are additionally `lgathered`, `rgathered`, and `multlined`. Note that an `aligned` environment avoids unnecessary space on the left and right; thus, it mostly resembles the `flalign` environment.

Like `minipage`, these environments take an optional argument that specifies the vertical positioning with respect to the material on either side. The default alignment of the box is centered (`[c]`). Of course, like `split`, they are used only within equations, and they never produce tags.

$x^2 + y^2 = 1$ $x = \sqrt{1 - y^2}$ and also $y = \sqrt{1 - x^2}$	$(a + b)^2 = a^2 + 2ab + b^2$ $(a + b) \cdot (a - b) = a^2 - b^2$	<pre> \usepackage{amsmath} \begin{equation} \begin{aligned} x^2 + y^2 &= 1 \\ x &= \sqrt{1 - y^2} \\ \text{and also } y &= \sqrt{1 - x^2} \end{aligned} \quad \begin{aligned} (a + b)^2 &= a^2 + 2ab + b^2 \\ (a + b) \cdot (a - b) &= a^2 - b^2 \end{aligned} \end{equation} </pre>
--	---	--

11-2-17

The same mathematics can also be typeset, albeit not very beautifully, using different vertical alignments for the environments.

11-2-18

$$\begin{aligned} x^2 + y^2 &= 1 \\ x &= \sqrt{1 - y^2} \\ \text{and also } y &= \sqrt{1 - x^2} \end{aligned} \quad \begin{aligned} (a + b)^2 &= a^2 + 2ab + b^2 \\ (a + b) \cdot (a - b) &= a^2 - b^2 \end{aligned} \quad (1)$$

```
\usepackage{amsmath}
\begin{equation}
\begin{aligned}[b]
x^2 + y^2 &= 1 \\
x &= \sqrt{1-y^2} \\
\text{and also } y &= \sqrt{1-x^2}
\end{aligned}
\end{equation}
\quad
\begin{gathered}[t]
(a + b)^2 = a^2 + 2ab + b^2 \\
(a + b) \cdot (a - b) = a^2 - b^2
\end{gathered}
\end{equation}
```

They may be used in many ways — for example, to do some creative and useful grouping of famous equations. Incidentally, these mini-page display environments are among the very few from `amsmath` that are robust enough to be used inside other definitions, as in the following example:

11-2-19

$$\left. \begin{aligned} \mathbf{B}' &= -c\nabla \times \mathbf{E} \\ \mathbf{E}' &= c\nabla \times \mathbf{B} - 4\pi\mathbf{J} \end{aligned} \right\} \text{Maxwell's equations}$$

```
\usepackage{amsmath,bm}
\newenvironment{rcases}
{\left.\begin{aligned}}
{\end{aligned}\right\}\text{rcases}}
\begin{equation*}
\begin{rcases}
\bm{B}' &= -c\nabla\times\bm{E} \\
\bm{E}' &= c\nabla\times\bm{B} - 4\pi\bm{J}
\end{rcases}
\quad \text{Maxwell's equations}
\end{equation*}
```

You can also use the `\minalignsep` command to control the space between pairs of columns in an `aligned` environment, as shown in the next example:

11-2-20

$$\begin{aligned} V_j &= v_j & X_i &= x_i - q_i x_j & & = u_j + \sum_{i \neq j} q_i \\ V_i &= v_i - q_i v_j & X_j &= x_j & & U_i &= u_i \end{aligned} \quad (1)$$

```
\usepackage{amsmath}
\renewcommand\minalignsep{5pt}
\begin{equation} \begin{aligned}
V_j &= v_j & X_i &= x_i - q_i x_j & & = u_j + \sum_{i \neq j} q_i \\
V_i &= v_i - q_i v_j & X_j &= x_j & & U_i &= u_i
\end{aligned} \end{equation}
```

As mentioned earlier, `mathtools` adds three additional environments that box their content. In contrast to `gathered` that centers the display lines, `lgathered` aligns them on the left and `rgathered` on the right. Both environments are defined

*mathtools additions
to amsmath*

with the help of a declaration `\newgathered`, through which you can define more complicated display environments that “gather and box” their content.

```
\newgathered{env-name}{line-start}{line-end}{after}
```

This defines a new environment with the name *env-name*. It collects all display lines and prepends *line-start* to each line and *line-end* after it. Finally, when the display is finished, it executes the *after-code*, which can be used to do some housekeeping. Using this command, all that was necessary to provide the `lgathered` environment in the package was the following declaration:

```
\newgathered{lgathered}{}{\hfil}{}{}
```

Existing environments can be redefined using `\renewgathered` instead.

```
\usepackage{mathtools} \newcounter{xgnum}
\newcommand{xgnum}{\stepcounter{xgnum}\textbf{\arabic{xgnum}*}}
\newgathered{xgathered}{\xgnum\quad\hfil}{\hfil}{\setcounter{xgnum}{0}}
```

Using these definitions in the next example, we get the following result:

$\begin{array}{ll} 1^* & x_0 = 1, \quad x_1 = 2 \\ 2^* & x_3 = 3 \end{array}$	(1)	<pre>% xgathered as defined above \begin{gather} \begin{xgathered} x_0=1,\quad x_1=2 \\\ x_3=3 \end{xgathered} \end{gather}</pre>	11-2-21
---	-------	---	---------

The third environment is `multlined`, which is the boxed version of `multline` discussed on page 134. In contrast to the other boxed environments, it has two optional arguments: the first defines the vertical position of the result as usual and accepts the value *b*, *t*, or *c* (default), and with the second you can specify an explicit width for the resulting box. If the *width* argument is not given, then the box is made wide enough to ensure that all continuation lines are indented compared to the first and that the last line slightly sticks out to the right. To indicate the box size, we added vertical delimiters to the left and right in the next example.

$\left \begin{array}{l} (a+b)^2 = \\ (a+b)(a+b) \\ = a^2 + 2ab + b^2 \end{array} \right $	<pre>\usepackage{mathtools} \left[\begin{multlined}[c] (a+b)^2 = \ (a+b)(a+b) \ = a^2 + 2ab + b^2 \end{multlined} \right]</pre>	11-2-22
--	--	---------

The commands `\shoveleft` and `\shoveright` also work with `multlined`, but there are a number of limitations with the environment; see the package documentation if you run into problems.

11.2.9 Interrupting displays with short text

The `\intertext` command is used for a short passage of text (typically at most a few lines) that appears between the lines of a display alignment. Its importance stems from the fact that all the alignment properties are unaffected by the text, which itself is typeset as a normal paragraph set to the display width; this alignment would not be possible if you simply ended the display and then started a new display after the text. This command may appear only immediately after a `\\` or `*` command.

Here the words “and finally” are outside the alignment, at the left margin, but all three equations are aligned.

11-2-23

and finally

$$A_1 = N_0(\lambda; \Omega') - \phi(\lambda; \Omega') \quad (1)$$

$$A_2 = \phi(\lambda; \Omega')\phi(\lambda; \Omega) \quad (2)$$

$$A_3 = \mathcal{N}(\lambda; \omega) \quad (3)$$

```
\usepackage{amsmath}
\begin{align}
A_1 &= N_0 (\backslash lambda ; \backslash Omega') -
&\quad \backslash phi ( \backslash lambda ; \backslash Omega') \quad \backslash\backslash
A_2 &= \backslash phi (\backslash lambda ; \backslash Omega')
&\quad \backslash phi (\backslash lambda ; \backslash Omega) \quad \backslash\backslash
\intertext{and finally}
A_3 &= \mathcal{N} (\backslash lambda ; \backslash omega)
\end{align}
```

In some situations, such as in the previous example where only short text is used, the vertical separation between the formula parts and the interruption appears to be too large, and for such cases `mathtools` offers `\shortintertext` as an alternative; see Example 11-4-25 on page 174.

*mathtools addition
to amsmath*

11.2.10 Vertical space in and around displays

As is usual in \LaTeX , the optional argument `\\[dimension]` gives extra vertical space between two lines in all `amsmath` display environments (there must be no space between the `\\` and the `[` character delimiting the optional argument). The vertical spaces before and after each display environment are controlled by the following rubber lengths, where the values in parentheses are those for `\normalsize` with the (default) `10pt` option in the standard \LaTeX classes¹:

*Space within the
display...*

*...and around the
display*

`\abovedisplayskip`, `\belowdisplayskip` The normal vertical space added above and below a mathematical display (default `10pt` plus `2pt` minus `5pt`).

`\abovedisplayshortskip`, `\belowdisplayshortskip` The (usually smaller) vertical space added above and below a “short display” (`0pt` plus `3pt` and `6pt` plus `3pt` minus `3pt`, respectively). A *short display* is one that starts to the right of where the preceding text line ends.

If you look closely, you can observe the results of these space parameters in the following example. The second equation is surrounded by less space because the text

¹These defaults are very much improved by the $\mathcal{A}\mathcal{M}\mathcal{S}$ - \LaTeX document classes.

in front of it does not overlap with the formula.

We now have the following:

$$X = a \quad a = c$$

and thus we have

$$X = c \quad (1)$$

And now we do not get much space around the display!

```
\usepackage{amsmath}
```

We now have the following:

```
\[ X = a \quad a = c \]
```

and thus we have

```
\begin{equation} X = c \end{equation}
```

And now we do not get much space around the display!

11-2-24

Since the four parameters `\abovedisplay..` and `\belowdisplay..` depend on the current font size, they cannot be modified in the preamble of the document using `\setlength`. Instead, they must be changed by modifying `\normalsize`, `\small`, and similar commands—a job usually done in a document class. More precisely, they can be changed mid-document, but their change survives only until the next font sizing command. This also explains why a change in the preamble has no effect: at `\begin{document}` a call to `\normalsize` is executed.

*Be wary of empty
lines around
displays*

Many authors wisely use empty lines between major structures in the document source to make it more readable. In most cases, such as before and after a heading, these empty lines do no harm. This is not universally true, however. Especially around and within mathematical display environments, one has to be quite careful: a blank line in front of such an environment produces unexpected formatting because the empty line is in effect converted into a paragraph containing no text (and so containing just the invisible paragraph indentation box). The following display is consequently surrounded by spaces of size `..displayshortskip`. Thus, the combined result is quite a lot of (possibly too much) space before the display (a whole empty line plus the `\abovedisplayshortskip`) and a very small amount of space after the display, as this example shows. To show the spacing issue more clearly we have internally set both `\abovedisplayshortskip` and `\belowdisplayshortskip` to 0pt for the next two examples. As a result there is “just” the empty line above and no space below the two displays.

```
\usepackage{amsmath}
```

Empty line before display:

Empty line before display:

$$a \neq b$$

In both cases, too much space before! ...

$$a \neq b \quad (1)$$

... and not a lot of space after!

```
\[ a \neq b \]
```

In both cases, too much space before! `\ldots`

```
\begin{equation} a \neq b \end{equation}
```

```
\ldots\ and not a lot of space after!
```

11-2-25

With the `amsmath` package loaded, this behavior is exhibited by all the display math environments. Strangely enough, with standard \LaTeX the `\[` case comes out looking more or less right. The reason is that standard \LaTeX pretends that an empty

line in front of a \displaystyle display (but only for that one) has no height but a large width. It therefore overlaps with the formula, and thus `\abovedisplayskip` and `\belowdisplayskip` are applied.

11-2-26

Empty line before display:

$$a \neq b$$

Enough space now, but do not rely on it!

$$a \neq b \quad (1)$$

Less space after in this case!

% The behavior without amsmath

Empty line before display:

`\[a \neq b \]`

Enough space now, but do not rely on it!

`\begin{equation} a \neq b \end{equation}`

Less space after in this case!

Another problem is that an empty line introduces an unwanted break point in front of the display, thus `\predisplaypenalty` is no longer honored. To summarize, do not use empty lines around display environments! If you want a visual separation in your source, use an empty line with a `%` inside instead.

Sometimes the lines in a display appear to be too close together and you want to set them slightly farther apart. For individual lines this can be done with the optional argument to `\`, but if several lines are involved, it is more efficient to use the `spreadlines` environment offered by the `mathtools` package. It expects one argument and opens up all display lines in its scope by the specified amount.

*mathtools addition
to amsmath*

A gather with normal spacing:

$$A = \sum_{i=1}^n x_i \quad (1)$$

$$B = x_1 + x_2 + x_3 \quad (2)$$

And now spread farther apart:

$$A = \sum_{i=1}^n x_i \quad (3)$$

$$B = x_1 + x_2 + x_3 \quad (4)$$

11-2-27

`\usepackage{mathtools}`

A `\texttt{gather}` with normal spacing:

`\begin{gather}`

`A=\sum_{i=1}^n x_i \ \ B = x_1 + x_2 + x_3`

`\end{gather}`

And now spread farther apart:

`\begin{spreadlines}{15pt}`

`\begin{gather}`

`A=\sum_{i=1}^n x_i \ \ B = x_1 + x_2 + x_3`

`\end{gather}`

`\end{spreadlines}`

11.2.11 Page breaks in and around displays

Automatic page breaking before and after each display environment is controlled by the penalty parameters `\predisplaypenalty` (for breaking before a display; default 10000, i.e., no break allowed) and `\postdisplaypenalty` (for breaking after a display, default 0; i.e., break allowed). The defaults are already set in standard \TeX and are not changed by `amsmath`.

*Page breaks around
the display...*

...and within the display

Unlike standard \LaTeX , the `amsmath` display environments do not, by default, allow page breaks between lines of the display. The reason for this behavior is that correct page breaks in such locations depend heavily on the structure of the display, so they often require individual attention from the author.

With `amsmath` such individual control of page breaks is best achieved via the `\displaybreak` command, but it should be used only when absolutely necessary to allow a page break within a display. The command must go before the `\\`, at which a break may be taken, and it applies only to that line and can be used only within an environment that produces a complete display. Somewhat like standard \LaTeX 's `\pagebreak` (see Section 6.2.2 in [106]), `\displaybreak` takes an optional integer as its argument, with a value ranging from zero to four, denoting the desirability of the page break: `\displaybreak[0]` means “it is permissible to break here” without encouraging a break; `\displaybreak` with no optional argument is the same as `\displaybreak[4]` and forces a break. This command cannot be used to discourage or prevent page breaks. Note that it makes no sense to break within a “mini-page display”, as those environments should never be split over two pages.

This kind of adjustment is fine-tuning, like the insertion of line breaks and page breaks in text. It should therefore be left until your document is nearly finalized. Otherwise, you may end up redoing the fine-tuning several times to keep up with changing document content.

The command `\allowdisplaybreaks`, which obeys the usual \LaTeX scoping rules, is equivalent to putting `\displaybreak[0]` before every line end in any display environment within its scope; i.e., it allows page breaks anywhere in the math displays. The command can take an optional argument for finer control: `[1]` means allow page breaks but avoid them as far as possible, while `[2]` to `[4]` allow breaks with increasing permissiveness. Within the scope of an `\allowdisplaybreaks` command, the `*` command can be used to prohibit a page break and individual `\displaybreak` commands override both the default and the effect of an `\allowdisplaybreaks`.

11.2.12 `breqn` — Automatic line breaking in math displays

Shortly before his early death, Michael Downes (1958–2003) started to develop a sophisticated package for automatic line breaking in display math equations. Morten Høgholm adopted this code and made it available to the general public. These days it is maintained by him and Will Robertson.

```
\begin{dmath}[key/value list] formula \end{dmath}
```

The `dmath` environment corresponds to the `equation` environment with the difference that it automatically breaks the *formula* into different lines if necessary and aligns them at relation symbols or binary symbols (but then indented). There also exists a `dmath*` version that omits the equation number, i.e., it corresponds to `amsmath`'s `equation*` environment. With the help of the optional *key/value list*, several aspects of the display can be adjusted.

As a teaser we repeat Example 11-2-9 from page 136 but now use `dmath` instead of `split`. As you can see, the source gets much simpler now (relatively speaking), because we do not have to define alignment points, line breaks, extra `\phantoms`, etc., to get the formula adequately broken across several lines. All that is done automatically behind the scenes by the package.

If you compare the output of the two examples, you see that they are almost identical. The most noticeable difference is the move of the $+$ from the end of the second line to the third, but this is arguably even better than our manual layout in Example 11-2-9.

```
\usepackage{breqn}
\newcommand\ve{\varepsilon} \newcommand\tve{t_{\varepsilon}}
\newcommand\vf{\varphi} \newcommand\yvf{y_{\varphi}}
\newcommand\bfE{\mathbf{E}}
\begin{dmath}
  f_{h,\ve}(x,y) = \ve \bfE_{x,y} \int_0^{t_{\ve}} L_{x,y_{\ve}(u)} \vf(x) \, du
  = h \int L_{x,z} \vf(x) \rho_x(dz) + h
  \biggl[ \frac{1}{t_{\ve}}
    \biggl( \bfE_y \int_0^{t_{\ve}} L_{x,y^x(s)} \vf(x) \, ds
    - \tve \int L_{x,z} \vf(x) \rho_x(dz) \biggr)
    + \frac{1}{t_{\ve}}
    \biggl( \bfE_y \int_0^{t_{\ve}} L_{x,y^x(s)} \vf(x) \, ds
    - \bfE_{x,y} \int_0^{t_{\ve}} L_{x,y_{\ve}(s)} \vf(x) \, ds
    \biggr) \biggr]
\end{dmath}
```

$$\begin{aligned}
 f_{h,\varepsilon}(x,y) &= \varepsilon \mathbf{E}_{x,y} \int_0^{t_\varepsilon} L_{x,y_\varepsilon(u)} \varphi(x) \, du \\
 &= h \int L_{x,z} \varphi(x) \rho_x(dz) \\
 &\quad + h \left[\frac{1}{t_\varepsilon} \left(\mathbf{E}_y \int_0^{t_\varepsilon} L_{x,y^x(s)} \varphi(x) \, ds - t_\varepsilon \int L_{x,z} \varphi(x) \rho_x(dz) \right) \right. \\
 &\quad \left. + \frac{1}{t_\varepsilon} \left(\mathbf{E}_y \int_0^{t_\varepsilon} L_{x,y^x(s)} \varphi(x) \, ds - \mathbf{E}_{x,y} \int_0^{t_\varepsilon} L_{x,y_\varepsilon(s)} \varphi(x) \, ds \right) \right] \tag{1}
 \end{aligned}$$

By default `breqn` breaks and aligns the formula on the first relation symbol, which may not be the optimal choice if there are several relation symbols in quick succession as in the next example:

```
\usepackage{breqn}
\begin{dmath} 0 < x =
  x_0 + x_1 + x_2 + x_3 + \dots + x_{n-1} + x_n
\end{dmath}
```

For this problem `breqn` offers two solutions. With `\hidere1` you can hide a relation symbol so that it is not considered as a potential break and alignment point. The result is shown in the next example:

$0 < x = x_0 + x_1 + x_2 + x_3 + \cdots + x_{n-1} + x_n \quad (1)$	<pre style="font-family: monospace; font-size: 0.9em;">\usepackage{breqn} \begin{dmath} 0 \hidere1{<} x = x_0 + x_1 + x_2 + x_3 + \dots + x_{n-1} + x_n \end{dmath}</pre>	11-2-30
--	--	---------

Alternatively, you can use the key `compact` that directs the environment to fill the lines as best as possible without attempting to align them at relation symbols. In the example we also used the key `spread` to ask for some extra line separation. There are several other keys available; see the package documentation [46] for details.

$0 < x = x_0 + x_1 + x_2 + x_3 + \cdots + x_{n-1} + x_n \quad (1)$	<pre style="font-family: monospace; font-size: 0.9em;">\usepackage{breqn} \begin{dmath}[compact,spread=1pt] 0 < x = x_0 + x_1 + x_2 + x_3 + \dots + x_{n-1} + x_n \end{dmath}</pre>	11-2-31
--	--	---------

*Multiformula
displays do not
work* 

The `dmath` environment assumes that it contains only a single logical formula and therefore aligns all continuation lines to the right of the relation from the first line. This means that placing several independent formulas into it always comes out wrong, even if you try to add an explicit `\\` to indicate the line break. In the latter case $(a - b)^2$ would end on a line by itself, vertically aligned with the equal signs above and below. Bottom line, for such multiformula displays you have to use the grouping environments discussed below and not what is shown in the next example:

<p>A bad result:</p> $(a + b)^2 = a^2 + 2ab + b^2(a - b)^2 = a^2 - 2ab + b^2 \quad (1)$	<pre style="font-family: monospace; font-size: 0.9em;">\usepackage{breqn} A bad result: \begin{dmath} (a+b)^2 = a^2 + 2ab + b^2 % A \\ is not helping; % see explanation above! (a-b)^2 = a^2 - 2ab + b^2 \end{dmath}</pre>	11-2-32
---	---	---------

The package offers a number of other environments and commands; we show two of them in the next example.

With the environment `dgroup*` you can group a number of `dmath` or `dmath*` environments; the result is comparable to `amsmath`'s `align` environment with one alignment point. If instead you use `dgroup`, then the whole group uses one equation number with subnumbering applied, i.e., (1a), (1b), etc.

Also shown is `\condition`, which is similar to the `\text` command but automatically adds punctuation and extra spacing.

11-2-33

$(a+b)^2 = a^2 + 2ab + b^2 \quad (1)$ $(a-b)^2 = a^2 - 2ab + b^2 \quad (2)$ $(a+b)(a-b) = a^2 - b^2$ $\frac{1}{x}, \quad \text{for } x \neq 0 \quad (3)$	<pre> \usepackage{breqn} \begin{dgroup*} \begin{dmath} (a+b)^2 = a^2+2ab+b^2 \end{dmath} \begin{dmath} (a-b)^2 = a^2-2ab+b^2 \end{dmath} \begin{dmath*} (a+b)(a-b) = a^2-b^2 \end{dmath*} \end{dgroup*} \begin{dmath} \frac{1}{x} \condition{for \$x\ne 0\$} \end{dmath} </pre>
---	---

As you can imagine, the package has to change a lot of the internal code that defines characters for math mode in order to identify which symbols are relations and binary symbols and are therefore candidates for line breaks. This is done in a helper package `flexsym` that redefines `\DeclareMathSymbol` among other things. This way packages such as `stmaryrd` that define additional math symbols can do this in a way that allows them participate in the line-breaking effort of `breqn` as long as they are loaded after that package. For `amssymb` and core \LaTeX symbols this is not necessary because the package knows about them and does the necessary adjustment regardless of the loading order. More detail is given in the package documentation.

 *Loading order
of math font
packages with
respect to breqn*

While on the whole the package produces impressive results, there are unfortunately a number of cases where it fails or has problems. If you intend to use it, you should read the package documentation [46] carefully to understand the current limitations and the situations where manual breaking of display formulas is simply the safer bet.

11.2.13 Equation numbering and tags

In \LaTeX the tags for equations are typically generated automatically and contain a printed representation of the \LaTeX counter `equation`. This involves three processes: setting (normally by incrementing) the value of the equation counter, formatting the tag, and printing it in the correct position.

In practice, the first two processes are nearly always linked. Thus, the value of the `equation` counter is increased only when a tag containing its representation is automatically printed. For example, when a mathematical display environment has both starred and unstarred forms, the unstarred form automatically tags each logical equation, while the starred form does not. Only in the unstarred form is the value of the `equation` counter changed.

Within the unstarred forms the setting of a tag (and the incrementing of the counter value) for any particular logical equation can be suppressed by putting `\notag` (or `\nonumber`¹) before the `\\`. You can override the default automatic tag with one of your own design (or provide a new one) by using the command `\tag`

¹The command `\notag` is interchangeable with `\nonumber`.

before the `\\`. The argument of this command can be arbitrary normal text that is typeset (within the normal parentheses) as the tag for that equation.

Note that the use of `\tag` suppresses the incrementing of the counter value. Thus, the default tag setting is only visually the same as `\tag{\theequation}`; they are not equivalent forms. The starred form, `\tag*`, causes the text in its argument to be typeset without the parentheses (and without any other material that might otherwise be added with a particular document class).

$x^2 + y^2 = z^2$	(1)	<code>\usepackage{amsmath}</code>	
$x^3 + y^3 = z^3$		<code>\begin{align}</code>	
$x^4 + y^4 = r^4$	(*)	<code>x^2+y^2 &= z^2 \label{eq:A}</code>	<code>\\</code>
$x^5 + y^5 = r^5$	*	<code>x^3+y^3 &= z^3 \notag</code>	<code>\\</code>
$x^6 + y^6 = r^6$	(1')	<code>x^4+y^4 &= r^4 \tag{***}</code>	<code>\\</code>
		<code>x^5+y^5 &= r^5 \tag{***}</code>	<code>\\</code>
		<code>x^6+y^6 &= r^6 \tag{\ref{eq:A}\$'\$}</code>	<code>\\</code>
		<code>\end{align}</code>	

11-2-34

Notice this example's use of the `\label` and `\ref` commands to provide some kinds of "relative numbering" of equations. If you want to repeat the tag number from the previous line with some extra mark, it is, of course, simpler to use `\theequation` to retrieve it.

$A_1 = N_0(\lambda; \Omega') - \phi(\lambda; \Omega')$	(1)	<code>\usepackage{amsmath}</code>	
$A_2 = \phi(\lambda; \Omega') \phi(\lambda; \Omega)$	ALSO (1)	<code>\begin{align}</code>	
$A_3 = \mathcal{N}(\lambda; \omega)$	(2)	<code>A_1 &= N_0 (\lambda ; \Omega\omega')</code>	
		<code>- \phi (\lambda ; \Omega\omega') \\</code>	
		<code>A_2 &= \phi (\lambda ; \Omega\omega')</code>	
		<code>\, , \phi (\lambda ; \Omega\omega)</code>	
		<code>\tag*{ALSO (\theequation)} \\</code>	
		<code>A_3 &= \mathcal{N} (\lambda ; \omega\omega)</code>	
		<code>\end{align}</code>	

11-2-35

Referencing equations

To facilitate the creation of cross-references to equations, the `\eqref` command (used in Example 11-2-40 on page 153) automatically adds the parentheses around the equation number, adding an italic correction if necessary. See also Section 2.4 on page 75 for more general solutions to managing references.

11.2.14 Fine-tuning tag placement

Optimal placement of equation number tags can be a rather complex problem in multiple-line displays. These display environments try hard to avoid overprinting an equation number on the equation contents; if necessary, the number tag is moved down or up, onto a separate line. The difficulty of accurately determining the layout of a display can occasionally result in a tag placement that needs further adjustment. Here is an example of the kind of thing that can happen and a strategy for fixing it. The automatic tag placement is clearly not very good.

```

\usepackage{amsmath}
\begin{equation} \begin{split}
\lvert I_2 \rvert &= \left\lvert \int_0^T \psi(t) \left\{ u(a,t) - \int_{\gamma(t)}^a \frac{d\theta}{k}(\theta,t) \int_a^\theta c(\xi) u_t(\xi,t) d\xi \right\} dt \right\rvert \\
&\leq C_6 \left\| f \int_\Omega \left| \tilde{S}_{a,-}^{-1,0} W_2(\Omega, \Gamma_l) \right| \left\| |u| \overset{\circ}{\rightarrow} W_2^{\tilde{A}}(\Omega; \Gamma_r, T) \right\| \right\| \\
&\quad \left\| \tilde{S}_{a,-}^{-1,0} W_2(\Omega, \Gamma_l) \right\| \left\| |u| \overset{\circ}{\rightarrow} W_2^{\tilde{A}}(\Omega; \Gamma_r, T) \right\|
\end{split} \\
\end{equation}
A line of text after the equation \ldots

```

11-2-36

$$\begin{aligned}
|I_2| &= \left| \int_0^T \psi(t) \left\{ u(a,t) - \int_{\gamma(t)}^a \frac{d\theta}{k}(\theta,t) \int_a^\theta c(\xi) u_t(\xi,t) d\xi \right\} dt \right| \\
&\leq C_6 \left\| f \int_\Omega \left| \tilde{S}_{a,-}^{-1,0} W_2(\Omega, \Gamma_l) \right| \left\| |u| \overset{\circ}{\rightarrow} W_2^{\tilde{A}}(\Omega; \Gamma_r, T) \right\| \right\|
\end{aligned} \tag{1}$$

A line of text after the equation ...

A fairly easy way to improve the appearance of such an equation is to use an `align` environment instead together with a `\notag` on the first equation line:

```

\begin{align}
\lvert I_2 \rvert &= \left\lvert \int_0^T \psi(t) \left\{ u(a,t) - \int_{\gamma(t)}^a \frac{d\theta}{k}(\theta,t) \int_a^\theta c(\xi) u_t(\xi,t) d\xi \right\} dt \right\rvert \\
&\leq C_6 \left\| f \int_\Omega \left| \tilde{S}_{a,-}^{-1,0} W_2(\Omega, \Gamma_l) \right| \left\| |u| \overset{\circ}{\rightarrow} W_2^{\tilde{A}}(\Omega; \Gamma_r, T) \right\| \right\| \\
&\quad \left\| \tilde{S}_{a,-}^{-1,0} W_2(\Omega, \Gamma_l) \right\| \left\| |u| \overset{\circ}{\rightarrow} W_2^{\tilde{A}}(\Omega; \Gamma_r, T) \right\|
\end{align}

```

This produces a good visual result, but note that it misuses logical markup—it assumes the equation numbers to be on the right! It also means that to the system your single equation is represented as two separate equations; i.e., any software that tries to interpret the markup (such as a screen reader) will therefore misunderstand it.

11-2-37

$$\begin{aligned}
|I_2| &= \left| \int_0^T \psi(t) \left\{ u(a,t) - \int_{\gamma(t)}^a \frac{d\theta}{k}(\theta,t) \int_a^\theta c(\xi) u_t(\xi,t) d\xi \right\} dt \right| \\
&\leq C_6 \left\| f \int_\Omega \left| \tilde{S}_{a,-}^{-1,0} W_2(\Omega, \Gamma_l) \right| \left\| |u| \overset{\circ}{\rightarrow} W_2^{\tilde{A}}(\Omega; \Gamma_r, T) \right\| \right\|
\end{aligned} \tag{1}$$

A line of text after the equation ...

As a better alternative the `\raisetag` command is available that adjusts the vertical position of the current equation number but *only* when it has been automatically moved from its “normal position”. For example, to move the tag in Example 11-2-36 upward we could have added `\raisetag{21pt}` and achieved the result below without using logically incorrect markup. Finding the appropriate value may need some trials, but once you used the command a couple of times, it is usually easy. Note that the text following will also get closer to the display if the tag is raised.

$$\begin{aligned} |I_2| &= \left| \int_0^T \psi(t) \left\{ u(a, t) - \int_{\gamma(t)}^a \frac{d\theta}{k}(\theta, t) \int_a^\theta c(\xi) u_t(\xi, t) d\xi \right\} dt \right| \\ &\leq C_6 \left\| f \int_\Omega |\tilde{S}_{a,-}^{-1,0} W_2(\Omega, \Gamma_l)| \left\| |u| \overset{\circ}{\rightarrow} W_2^{\tilde{A}}(\Omega; \Gamma_r, T) \right\| \right\| \quad (1) \end{aligned}$$

11-2-38

A line of text after the equation ...

A different use is shown in the next example, where `\raisetag` with a negative argument is used to move the tag on the left down into the display.

(1)

The sign function: $\mathcal{S}(x) = \begin{cases} -1 & x < 0 \\ 0 & x = 0 \\ 1 & x > 0 \end{cases}$

```

\usepackage[leqno]{amsmath}
\begin{gather} \raisetag[-10pt]
\text{The sign function: } \backslash
\mathcal{S}(x) = \begin{cases}
-1 & \& x < 0 \backslash \backslash
0 & \& x = 0 \backslash \backslash
1 & \& x > 0
\end{cases} \end{gather}

```

11-2-39

Here we used a `gather` environment with a single line because the `equation` environment is (the only) one within which `\raisetag` unfortunately has no effect (it is coded using low-level TeX).

These kinds of adjustment constitute “fine-tuning”, like line breaks and page breaks in text. They should therefore be left until your document is nearly finalized. Otherwise, you may end up redoing the fine-tuning several times to keep up with changing document content.

11.2.15 Subordinate numbering sequences

The `amsmath` package provides a `subequations` environment to support “equation subnumbering” with tags of the form (2a), (2b), (2c), and so on. All the tagged equations within it use this subnumbering scheme based on two normal L^AT_EX counters: `parentequation` and `equation`.

The next example demonstrates that the tag can be redefined to some extent, but note that the redefinition for `\theequation` must appear within the `subequations`

environment! (Appendix A.2.1 discusses counter manipulations.)

		<code>\usepackage{amsmath}</code>
		<code>\begin{subequations} \label{eq:1}</code>
$f = g$	(1a)	<code>\begin{align} f &= g \quad \quad \quad \backslash\label{eq:1A} \backslash</code>
$f' = g'$	(1b)	<code> f' &= g' \quad \quad \quad \backslash\label{eq:1B} \backslash</code>
$\mathcal{L}f = \mathcal{L}g$	(1c)	<code> \mathcal{L}f &= \mathcal{L}g \quad \backslash\label{eq:1C}</code>
		<code>\end{align}</code>
		<code>\end{subequations}</code>
		<code>\begin{subequations} \label{eq:2}</code>
		<code>\renewcommand\theequation</code>
		<code> \{\theparentequation\roman{equation}\}</code>
$f = g$	(2i)	<code>\begin{align} f &= g \quad \quad \quad \backslash\label{eq:2A} \backslash</code>
$f' = g'$	(2ii)	<code> f' &= g' \quad \quad \quad \backslash\label{eq:2B} \backslash</code>
$\mathcal{L}f = \mathcal{L}g + K$	(2iii)	<code> \mathcal{L}f &= \mathcal{L}g + K \quad \backslash\label{eq:2C}</code>
		<code>\end{align}</code>
		<code>\end{subequations}</code>
Note the relationship between (1)		Note the relationship between~\eqref{eq:1}
and (2): only 1c and 2iii differ.		and~\eqref{eq:2}: only~\ref{eq:1C} and~\ref{eq:2C} differ.

11-2-40

The `subequations` environment must appear *outside* the displays that it affects. Also, it should not be nested within itself. Each use of this environment advances the “main” equation counter by one. A `\label` command within the `subequations` environment but outside any individual (logical) equation produces a `\ref` to the parent number (e.g., to 2 rather than 2i).

11.2.16 Resetting the equation counter

It is a fairly common practice to have equations numbered within sections or chapters, using tags such as (1.1), (1.2), ..., (2.1), (2.2), These days this can be easily set up with standard \LaTeX by using the declaration `\counterwithin`.¹

For example, to get compound equation tags including the section number, with the equation counter being automatically reset for each section, put this declaration in the preamble: `\counterwithin{equation}{section}`.

Sometimes such a setup is already done by the document class you use, e.g., the report or book classes of standard \LaTeX number equations per chapter. If you would like to undo such a setting, use `\counterwithout`.

11.3 Matrix-like environments

The `amsmath` package offers a number of matrix-like environments, all of which are similar to `array` in syntax and layout. Thinking of complex mathematical layouts in

¹As the name implies, `\counterwithin` can be applied to any pair of counters, but the results may not be satisfactory in all cases because of potential complications. See the explanations in Appendix A.2.1 where these commands are further discussed.

this way is a useful exercise, as quite a wide variety of two-dimensional mathematical structures and table-like layouts can be described like this.

*Old “plain T_EX”
commands disabled*

Three of these environments replace old commands that are kept well hidden in standard L^AT_EX: `matrix` and `pmatrix` (discussed in the next section) and `cases` (discussed in the section after that). Because these old command forms use a totally different notation inherited from plain T_EX, they are not truly part of L^AT_EX, and they cannot be mixed with the environment forms described here. Indeed, `amsmath` produces an explanatory error message if one of the old commands is used (see page 735). If, contrariwise, you make the mistake of using the `amsmath` environment forms without loading that package, then you most probably get this error message: “Misplaced alignment tab character &”.

With `delarray` and `bigdelim`, two further packages are described that allow placing various delimiters around and within matrix-like structures. The section concludes with a discussion of two commutative diagram packages: `amscd` and `tikz-cd`.

11.3.1 `amsmath`, `mathtools` — The matrix environments

The matrix environments are similar to L^AT_EX’s `array`, except that they do not have an argument specifying the formats of the columns. Instead, a default format is provided: up to ten centered columns. Also, the spacing differs slightly from the default in `array`. The example below illustrates the matrix environments `matrix`, `pmatrix`, `bmatrix`, `Bmatrix`, `vmatrix`, and `Vmatrix`¹:

$\begin{matrix} 0 & 1 \\ 1 & 0 \end{matrix} \quad \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}$	<pre>\usepackage{amsmath} \begin{gather*} \begin{matrix} \backslash begin{matrix} 0 & 1 \backslash \backslash 1 & 0 \backslash end{matrix} \quad \\ \backslash begin{pmatrix} 0 & -i \backslash \backslash i & 0 \backslash end{pmatrix} \end{matrix} \\[10pt] \begin{matrix} \backslash begin{bmatrix} 0 & -1 \backslash \backslash 1 & 0 \backslash end{bmatrix} \quad \\ \backslash begin{Bmatrix} 1 & 0 \backslash \backslash 0 & -1 \backslash end{Bmatrix} \end{matrix} \\[10pt] \begin{matrix} \backslash begin{vmatrix} a & b \backslash \backslash c & d \backslash end{vmatrix} \quad \\ \backslash begin{Vmatrix} i & 0 \backslash \backslash 0 & -i \backslash end{Vmatrix} \end{matrix} \end{gather*}</pre>
$\begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix} \quad \begin{Bmatrix} 1 & 0 \\ 0 & -1 \end{Bmatrix}$	
$\begin{vmatrix} a & b \\ c & d \end{vmatrix} \quad \begin{Vmatrix} i & 0 \\ 0 & -i \end{Vmatrix}$	

11-3-1

As in standard arrays, the amount of space between the columns is given by the value of `\arraycolsep`, but no space is added on either side of the array.

The maximum number of columns in a matrix environment is determined by the counter `MaxMatrixCols`, which you can change using L^AT_EX’s standard counter commands. With more columns L^AT_EX has to work a little harder and needs slightly more resources. However, with today’s typical T_EX implementations, such limits are less important, so setting `MaxMatrixCols` to 20 or higher is possible without a noticeable change in processing speed.

¹Note the warning above about possible problems when using `matrix` and `pmatrix`.

11-3-2

$$\begin{array}{cccccccccccc} a & b & c & d & e & f & g & h & i & j & \cdots \\ & a & b & c & d & e & f & g & h & i & \cdots \\ & & a & b & c & d & e & f & g & h & \cdots \\ & & & a & b & c & d & e & f & g & \cdots \\ & & & & \ddots & \ddots & \dots\dots\dots \end{array}$$

```
\usepackage{amsmath}
\setcounter{MaxMatrixCols}{20}

\[
\begin{Vmatrix}
\, , a&b&c&d&e&f&g&h&i&j \, &\cdots\, , \} \, \backslash \\
& a&b&c&d&e&f&g&h&i \, &\cdots\, , \} \, \backslash \\
& & a&b&c&d&e&f&g&h \, &\cdots\, , \} \, \backslash \\
& & & a&b&c&d&e&f&g \, &\cdots\, , \} \, \backslash \\
& & & & & \ddots&\ddots&\hdotsfor[2]{5}\, , \} \\
\end{Vmatrix} \, \backslash
```

This example also demonstrates the use of the command `\hdotsfor` to produce a row of dots in a matrix, spanning a given number of columns (here 5). The spacing of the dots can be varied by using the optional parameter (here 2) to specify a multiplier for the default space between the dots; the default space between dots is 3 math units (see Appendix A.2.4). The thin space and the brace group `{}` at the end of each row simply make the layout look better; together they produce two thin spaces, about 6mu or 1/3em. (Spacing in formulas is discussed in more detail in Section 11.7.7 on page 204.)

The `amsmath` matrix environment always centers the cell contents. As this is not always appropriate, the `mathtools` package adds starred forms of the environments that enable you to alter that behavior on a case-by-case basis.

<code>\begin{matrix*}[col-align]</code>	<i>content</i>	<code>\end{matrix*}</code>
<code>\begin{pmatrix*}[col-align]</code>	<i>content</i>	<code>\end{pmatrix*}</code>
<code>\vdots</code>		
<code>\begin{Vmatrix*}[col-align]</code>	<i>content</i>	<code>\end{Vmatrix*}</code>

All the environments have an additional optional *col-align* argument that specifies the column alignment. Allowed values are `l`, `r`, or `c` (default; i.e., if the optional argument is omitted, the starred environments behave like their unstarred variants).

To produce a small matrix suitable for use in text, use the `smallmatrix` environment. Note that the text lines are not spread apart even though the line before the small matrix contains words with descenders.

11-3-3

To show the effect of the matrix on surrounding lines inside a paragraph, we put it here $\begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix}$ and follow it with some more text on the next line.

`\usepackage{amsmath}`

To show the effect of the matrix on surrounding lines inside a paragraph, we put it here

```
$\left(\begin{smallmatrix}
```

-1 & 0 & 0 & -1 `\end{smallmatrix}\right)$`

and follow it with some more text on the next line.

Again, `mathtools` provides a corresponding starred environment `smallmatrix*` that allows altering the column alignments and also typesets the fencing delimiters automatically if you precede the environment name (starred or nonstarred form) with `p` (parentheses), `b` (brackets), `B` (braces), `v` (vertical bars), or `V` (double vertical

Another set of
mathtools additions

bars). We repeat the previous example but use braces as delimiters and right-align the columns:

To show the effect of the matrix on surrounding lines inside a paragraph, we put it here $\begin{Bmatrix} -1 & 0 \\ 0 & -1 \end{Bmatrix}$ and follow it with some more text on the next line.

```
\usepackage{mathtools}
```

To show the effect of the matrix on surrounding lines inside a paragraph, we put it here

```
\begin{Bsmallmatrix*}[r]
```

```
-1 & 0 \\ 0 & -1 \end{Bsmallmatrix*}$
```

and follow it with some more text on the next line.

11-3-4

11.3.2 amsmath, mathtools, cases — Some case environments

Constructions like the following, where a single equation has a few variants, are very common in mathematics. To handle these constructions, amsmath provides the `cases` environment. It produces a decorated array with two columns, both left aligned.

$$P_{r-j} = \begin{cases} 0 & \text{if } r-j \text{ is odd,} \\ r! (-1)^{(r-j)/2} & \text{if } r-j \text{ is even.} \end{cases} \quad (1)$$

```
\usepackage{amsmath}
```

```
\begin{equation} P_{\{r - j\} =
```

```
\begin{cases}
```

```
0 & \text{if } r - j \text{ is odd,} \\
```

```
r! \, , (-1)^{\{r - j\}/2}
```

```
& \text{if } r - j \text{ is even.}
```

```
\end{cases}
```

```
\end{equation}
```

11-3-5

Even though the right-most column usually contains explanatory text, it is processed in math mode. We therefore have to use `\text` with “embedded math mode” in the text strings as needed. The equation number is supplied by the outer environment: the individual cases are not labeled.

mathtools additions
to amsmath

The lines of the `cases` environments are processed in `\textstyle`, which may not be appropriate, if they contain operators taking limits. For this reason the `mathtools` packages defines `dcases` that works like `cases` but uses `\displaystyle` throughout. It also offers `rcases` and `drcases` that place the brace to the right instead of the left.

Thus, instead of defining `rcases` manually with the help of the `aligned` environment as we did in Example 11-2-19 on page 141, we could have used the `mathtools` environment directly:

$$\left. \begin{aligned} B' &= -c \nabla \times E \\ E' &= c \nabla \times B - 4\pi J \end{aligned} \right\} \text{Maxwell}$$

```
\usepackage{mathtools,bm}
```

```
\begin{equation*} \begin{rcases}
```

```
\bm{B}' = -c \nabla \times \bm{E}
```

```
\\
```

```
\bm{E}' = c \nabla \times \bm{B} - 4\pi \bm{J} \, ,
```

```
\end{rcases} \enspace \text{Maxwell}
```

```
\end{equation*}
```

11-3-6

To support the common situation that the explanation column contains text rather than a formula, `mathtools` also defines starred versions of all four environments that typeset only their first column in math mode.

An alternative approach is provided by the small package `cases` by Donald Arseneau. It defines two environments, `numcases` and `subnumcases`, that allow you to number each case with an equation (or subequation) number. Since they produce equation numbers, they are standalone display environments similar to `align`, whereas `cases` is like `aligned`, i.e., needs an outer environment such as `equation`.

The approach taken by the `cases` package

The material to the left of the cases is specified as an argument to the environment: the body then holds the different case lines. In contrast to the `cases` environment from `amsmath`, the “explanation” column is treated as text. Thus, there is no need to add `\text` as we had to in the previous example. Of course, if most of your explanations are mathematically stated, then you have to supply $\$$ signs each time.

If you want to omit an equation number on one line, you can use `\nonumber` before the `\\`. If the `amsmath` package is also loaded, then `\notag` works as well, and `\tag` can be used to manually specify a tag.

11-3-7

$$f(x) = \begin{cases} -1 & \text{if } x < 0, & (1a) \\ 0 & \text{if } x = 0, & (*) \\ 1 & \text{if } x > 0. & (1b) \end{cases}$$

Reference to a subequation (1b) and to the overall equation (1) are possible.

```
\usepackage{amsmath,cases}
\begin{subnumcases}{f(x) = \label{L1}}
-1 & if $x<0$,, & \\
0 & if $x=0$,, & \tag{$*$} \\
1 & if $x>0$,. & \label{L2}
\end{subnumcases}
```

Reference to a subequation `\eqref{L2}` and to the overall equation `\eqref{L1}` are possible.

As seen in the previous example, referencing the individual case numbers is done by placing a `\label` on the appropriate line. In the case of subnumbering, you can also refer to the main equation number (even though it is not shown) by placing the `\label` into the argument of the environment. When referencing, you can use `\ref` or `\pageref` as usual: in the example we used `\eqref` from the `amsmath` package.

Besides handling equation numbers differently, there is also a noticeable difference in spacing: the left brace has more space around it, and the space between the two columns is noticeably larger. What looks better is certainly a matter of opinion; personally I prefer Donald’s style over the more cramped `amsmath` one.

Given that one may want to use both `subnumcases` and `cases` in the same document, the `cases` package offers a number of options to bring both approaches closer together: `amsstyle` switches to the cramped spacing and treats the explanations as math, while `casesstyle` defines or redefines the `cases` environment in the style of the `cases` package, e.g., with more space and the explanations in text mode.

Altering the style

Finally, there is a `subnum` option that treats all `numcases` environments as `subnumcases`.

11.3.3 delarray — Delimiters surrounding an array

This section describes a useful general extension to the `array` package (see Section 6.2 on page 437) that allows the user to specify opening and closing extensible delimiters (see Section 11.5.6) to surround a mathematical `array` environment. The `delarray` package was written by David Carlisle, and its use is illustrated in the next, rather

odd-looking, example (note that the `delarray` package is independent of `amsmath`, but it automatically loads the `array` package if necessary).

$Q = \begin{pmatrix} X & Y \end{pmatrix} \begin{bmatrix} A & B \\ C & D \end{bmatrix} \begin{pmatrix} L \\ M \end{pmatrix}$	<pre style="font-family: monospace; font-size: 0.9em;">\usepackage{delarray} \[\mathcal{Q} = \begin{array}[t] ({cc}) X & Y \end{array} \begin{array}[t] [{cc}] A & B \ \ C & D \ \end{array} \begin{array}[b] \lgroup{c}\rgroup L \ \ M \end{array} \]</pre>	11-3-8
---	---	--------

The delimiters are placed on either side of the “preamble declaration” (here `{cc}`). They must be delimiters from Table 11.5 on page 190.

The most useful feature of this package is also illustrated in the preceding example: the use of the `[t]` and `[b]` optional arguments, which are not available with `amsmath`’s matrix environments. These show that the use of the `delarray` syntax is not equivalent to surrounding the `array` environment with `\left` and `\right`, because the delimiters are raised as well as the array itself.

11.3.4 bigdelim — Delimiters around and inside arrays

A different way of adding braces or other delimiters to arrays (or tabular structures) is provided by Pieter van Oostrum with the `bigdelim` package, which is based on his `multirow` package. In contrast to `delarray` where the delimiters are specified as part of the overall array specification or the matrix environment from `amsmath` where the environment name defines the used delimiters, this package requires dedicated array cells to be reserved for receiving the delimiters. Thus, if you want to build a three-column matrix surrounded by parentheses, you need to specify a five-column array, in which the first and last columns are there just to receive the delimiters.

If you think this is more work than with the other approaches, then this is a correct observation. However, while slightly more work, it also offers you more freedom in placement; e.g., you can let the delimiter embrace only some of the rows or even put a delimiter right in the middle of your array. Furthermore, you can attach material at the outside of the delimiter centered on its height, which is sometimes useful.

```
\ldelim{delim}[vmove]{rows}{width}[text]
\rdelim{delim}[vmove]{rows}{width}[text]
```

The two commands provided by the package are `\ldelim` and `\rdelim`. Their first argument is the *delimiter* to be placed, which can be any delimiter from Table 11.5 on page 190 that can vertically grow to arbitrary sizes.

In *rows* you specify how many rows this delimiter should span. The delimiter is placed starting in the cell where the command is used and extending the specified number of *rows* downwards. If the *rows* value is negative, it extends upwards. This can be useful in conjunction with colored tables (e.g., when using the `colortbl` package) because the delimiter is then placed on top of the already colored rows. Otherwise, color in later rows would come on top of the delimiter and thus effectively hide it.

With the optional *vmove* argument you can fine-tune the vertical position. If your rows are unusually high, you may have to slightly enlarge the *row* value (which can take fractional values) above the nominal number of rows to span.

In *width* you specify the space the delimiter and any *text* (if present) can take up. If you make that too small, you get an overfull box warning, and the material sticks out to the right; if you make it larger than the needed space, you will effectively produce white space at the right side of the delimiter. In some cases, that can be useful, but usually it is best to simply put a *** into this argument, which tells the command to use the natural width.¹ Finally, there is an optional *text* argument. If present, the *text* is placed vertically centered next to the delimiter, for `\ldelim` on the left and for `\rdelim` on the right.

In the next example we place two delimiters on the right, each covering only some of the rows. Note that we horizontally shifted one to the right so that they do not overprint each other. The brace on the left is printed starting from the last row to show how this is done. Also interesting is the `array` preamble where we used `@{\,}` between the data columns and the columns for the delimiters. This suppresses the usual separation between `array` rows and instead inserts only a tiny space.

11-3-9

$$\text{This is } \left[\begin{array}{ccc} 1 & 2 & 3 \\ 0 & 1 & 2 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{array} \right] \begin{array}{l} \text{quite} \\ \\ \\ \text{special} \end{array} \quad (1)$$

```
\usepackage{bigdelim}
\begin{equation}
\begin{array}{r@{\,}ccc@{\,}l}
& 1 & 2 & 3 & \hspace{2mm}\rdelim{3}{*}[quite] & \\
& 0 & 1 & 2 & & \\
& 0 & 0 & 1 & \rdelim{3}{*}[special] & \\
& 0 & 0 & 0 & & \\
\ldelim\{-5}{*}[This is] & & \Delta & & \end{array}
\end{equation}
```

11.3.5 Commutative diagrams with standard L^AT_EX

Simple commutative diagrams can in principle be produced by using an `array` environment and placing elements and arrows into appropriate cells. Of course, this allows only for horizontal and vertical connectors, and as you see in the next example, the results are only modestly satisfying, while the input is rather complex and difficult to read.

11-3-10

$$\begin{array}{ccc} S^{\mathcal{W}_\Lambda} \otimes T & \xrightarrow{j} & T \\ \downarrow & & \downarrow \text{End } P \\ (S \otimes T)/I & = & (Z \otimes T)/J \end{array}$$

```
\[ \begin{array}{ccc}
S^{\mathcal{W}_\Lambda} \otimes T & \xrightarrow{j} & T \\
\downarrow & & \downarrow \text{End } P \\
(S \otimes T)/I & = & (Z \otimes T)/J
\end{array} \]
```

¹This argument is inherited from `\multirow` where it makes much more sense to be able to specify a width. It would have made the usage simpler to hide it and internally always pass on ***. But given that it is there, you can perhaps sometimes use it to your advantage.

The `picture` environment could in theory be used for more complex commutative diagrams, but in practice this is the wrong tool as any changes in the diagram would require extensive manual recalculations of coordinates.

Fortunately, there are a number of specialized packages for producing sophisticated and beautiful diagrams, among them Kristoffer Rose's (1965–2016) XY-pic system and its extension [10] by Michael Barr (see [55, Chapter 7]).

For this book we selected two packages. One is the `amscd` package for producing simple commutative diagrams like the one from the previous example. The other package that allows for arbitrarily complex diagrams is `tikz-cd`, discussed at the end of the section.

11.3.6 `amscd` — Commutative diagrams à la AMS

Being based on the `array` environment, the `amscd` package allows only for horizontal and vertical connectors. It provides some useful shorthand forms for specifying the decorated arrows and other connectors, which makes the input easier and the results nicer, but otherwise it does not offer new features compared to standard \LaTeX .

In the CD environment the notations `@>>>`, `@<<<`, `@VVV`, and `@AAA` give right, left, down, and up arrows, respectively. The following examples also show the use of the command `\DeclareMathOperator` (see Section 11.6.2):

$ \begin{array}{ccccc} \text{cov}(L) & \longrightarrow & \text{non}(K) & \longrightarrow & \text{cf}(K) \\ \downarrow & & \uparrow & & \uparrow \\ \text{add}(L) & \longrightarrow & \text{add}(K) & \longrightarrow & \text{cov}(K) \end{array} $	<pre> \usepackage{amsmath,amscd} \DeclareMathOperator\add{add} \DeclareMathOperator\cf{cf} \DeclareMathOperator\cov{cov} \DeclareMathOperator\non{non} \[\begin{CD} \cov(L) @>>> \non(K) @>>> \cf(K) \\ @VVV @AAA @AAA \\ \add(L) @>>> \add(K) @>>> \cov(K) \end{CD} </pre>	11-3-11
--	---	---------

Decorations on the arrows are specified as follows. For the horizontal arrows, material between the first and second `>` or `<` symbols is typeset as a superscript, and material between the second and third is typeset as a subscript. Similarly, material between the first and second, or second and third, `As` or `Vs` of vertical arrows is typeset as left or right “side-scripts”; this format is used in the next example to place the operator $\text{End } P$ to the right of the arrow. The notations `@=` and `@|` give horizontal and vertical double lines. A “null arrow” (produced by `@.`) can be used instead of a visible arrow to fill out an array cell where needed.

$ \begin{array}{ccc} S^{W_\Lambda} \otimes T & \xrightarrow{j} & T \\ \downarrow & & \downarrow \text{End } P \\ (S \otimes T)/I & \longequal{\quad} & (Z \otimes T)/J \end{array} $	<pre> \usepackage{amsmath,amscd} \DeclareMathOperator{\End}{End} \[\begin{CD} S^{W_\Lambda} \otimes T @>j>> T \\ @VVV @VV{\text{End } P}V \\ (S \otimes T)/I @= (Z \otimes T)/J \end{CD} </pre>	11-3-12
--	--	---------

If you compare this to Example 11-3-10, it shows clearly how much better the results are with the `amscd` package: the notation is enormously easier and, for example, the package produces longer horizontal arrows and much improved spacing between elements of the diagram. The more specialized packages enable you to get even more beautiful results, as we see exemplified in the next section.

11.3.7 `tikz-cd` — Commutative diagrams based on `tikz`

The `tikz-cd` package by Augusto Stoffel is one of the more recent additions in the area of specialized packages for drawing and enables you to easily prepare arbitrarily complex commutative diagrams. It is based on the powerful `tikz` system for drawing¹ and is able to harness all of its powers if needed. Nevertheless, its input syntax is easy to learn, and the diagram sources are understandable, even without knowing the details of the package syntax as you will see below.

The package provides the environment `tikzcd` for producing diagrams. Inside, elements are laid out in a grid separated by `&`, and rows are separated by `\\` as usual. For specifying “arrows” between different element there is the command `\arrow` or its short form `\ar` if you do not like typing long command names.

`\arrow[options]` or `\ar[options]`

While the *options* argument is specified in brackets, it is not optional, because you need to specify at least the target direction through a combination of `l`, `r`, `u`, or `d` characters (for left, right, up, or down). For example, to have an arrow from the first element in the first row to the third element in the second row, you would specify `rrd`. Specifying labels for the arrows is done by surrounding their text with “`\math`” (typeset in math mode), and if you require a special arrow form, there is a multitude of keywords to adjust the shape, etc.

These basic features are exhibited in the next example where we reimplement Example 11-3-10 once more.

11-3-13

$ \begin{array}{ccc} S^{W_\Lambda} \otimes T & \xrightarrow{j} & T \\ \downarrow & & \downarrow \text{End } P \\ (S \otimes T)/I & \xlongequal{\quad} & (Z \otimes T)/J \end{array} $	<pre> \usepackage{amsmath,tikz-cd} \DeclareMathOperator\End{End} \begin{tikzcd} S^{W_\Lambda} \otimes T \arrow[r, "j"] \arrow[d] & T \arrow[d, "\text{End } P"] \\ (S \otimes T)/I \xlongequal{\quad} & (Z \otimes T)/J \end{tikzcd} </pre>
---	---

The `tikzcd` environment can be used inside or outside of math mode; e.g., if you need an equation number, place it into an `equation` environment. If used by its own, it does not add any vertical spacing and does not end the current paragraph, which explains the offset in the above example — the paragraph indentation. Thus, it is usually best to place it into `\[...]` or `equation` to achieve a consistent look and feel. However, it is unfortunately not possible to use it in environments that process

 *Restrictions*
with some math
display environments

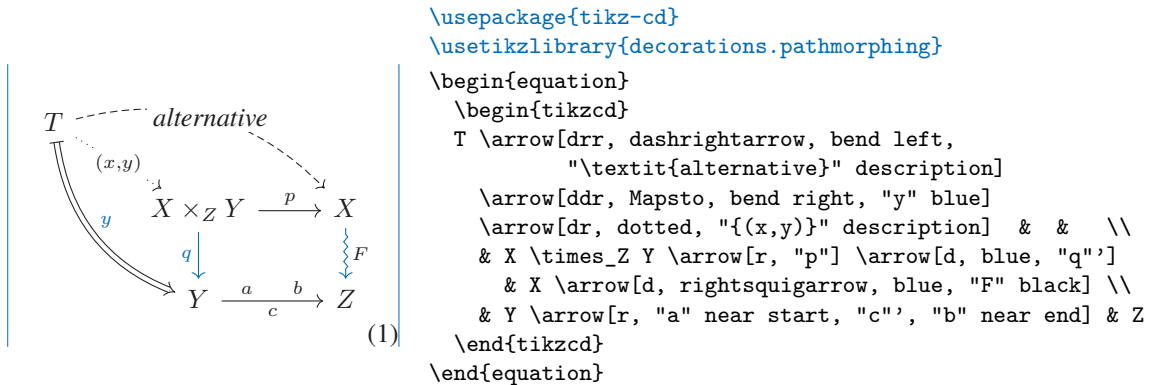

¹ See Section 8.5 on page 631 for further information on the `tikz` package.

their content several times to determine the final layout. This includes some of the other math display environments such as `align` or `gather`.

The number of keywords that can be used is quite large, so here we show only a small but hopefully useful fraction of them. If you need more, consult the nice manual [184]. As a teaser we show two more examples exhibiting several options. They are modified examples taken from the manual to show you most common variants. New features in the first one are several keywords for specifying different arrow shapes¹, some useful label placement options such as `near_start`, the `'` syntax that moves a label to the “other” side of the arrow, and ways to make simple curved arrows with `bend_left` or `bend_right`.

The `description` key places the label on top of the arrow. Note that this key should act on the label so should follow the label without a comma.

Finally, the package understands basic color names (and more can be defined). Such colors can be applied to just the label (e.g., the y in the example) or to the whole arrow *and* its labels, (as done for the downward arrows). To just get an arrow colored but not its labels you need to undo the coloring inside the label, which is why we explicitly made F black again to show how this can be done.

11-3-14

The final example shows that it is possible to apply the full power of `tikz` in specifying arrows. If you use other `tikz`-based packages more regularly, you probably immediately recognize the features; otherwise, take them as something to explore further if needed, because you will probably seldom need strange paths in your commutative diagrams. However, looping arrows are more common; we show two variants below. The other possible keywords for loops are not surprisingly called `loop_left` and `loop_down`.

The `dash` key is an arrow shape without head or tail, i.e., a straight line; dotted is a modifier that uses dots on the stem. A `hook` modifies the tail, and if you append a `'`, the hook goes into the opposite direction. In a similar fashion, `two_heads` modifies the head. Arrows can start at empty cells, but they need to end at a cell with content, which is why we had to place something invisible into the top-right corner.

¹Using the `rightsquigarrow` shape requires you to load an additional `tikz` library, but if you forget, it tells you so.

11-3-15

```
\usepackage{tikz-cd}
\begin{tikzcd}
A \arrow[dr, hook', controls={+(1.5,0.5) and +(-1,0.8)}]{}
\arrow[dr, dashed, to path=|- (\tikztotarget)]
\arrow[loop above, Rightarrow] & \mbox{} \\
\arrow[ur, dash, dotted] & B \arrow[loop right, two heads]{}
\end{tikzcd}
```

11.4 Compound structures and decorations

This section presents some commands that produce a variety of medium-sized mathematical structures including decorated symbols and fraction-like objects. Many of them are provided by the `amsmath` package, but in some cases further packages need to be loaded.

11.4.1 `amsmath`, `mathtools`, `extarrows` — Decorated arrows

The `amsmath` commands `\xleftarrow` and `\xrightarrow` produce horizontal relation arrows similar to those used for the commutative diagrams in Section 11.3.5; they are intended to have textual decorations above and/or below the arrow, and the length of the arrow is chosen automatically to accommodate the text. These arrows are normally available in only one size. Thus, they will probably not be suited for use in fractions, subscripts, or superscripts, for example.

The textual decorations below and above the arrows are specified in an optional and a mandatory argument to the command.

11-4-1

$$0 \xleftarrow[\zeta]{F \times \Delta(n-1)} E^{\partial_0 b}$$

```
\usepackage{amsmath}
\begin{gather}
0 \xleftarrow[\zeta]{F \times \Delta(n-1)} E^{\partial_0 b} \\
\end{gather}
```

Further extensible arrows with the same syntax for superscript and subscript material are provided by the `mathtools` package. This includes three double line arrows, two hook arrows, and various harpoons as shown in the next example. In the case of the double line arrows, you may have to add some extra spacing inside the arguments to avoid the material bumping into the arrowhead (as we did with `_` in the example); for the harpoons this is usually not necessary.

*mathtools additions
to amsmath*

11-4-2

$$A \xleftrightarrow[x]{y} B \Rightarrow C \xleftrightarrow[y]{x} D \quad (1)$$

$$A \xleftrightarrow[b]{a} B \xleftrightarrow[bbb]{a} C \quad (2)$$

$$\xleftrightarrow[\text{yy}]{\text{xxx}} \quad (3)$$

$$\xrightarrow[\text{letters}]{x>0} A \longleftrightarrow Z \quad (4)$$

```
\usepackage{mathtools}
\begin{gather}
A \xleftrightarrow[x]{y} B \xrightarrow[y]{x} C \xleftrightarrow[y]{x} D \\
A \xleftrightarrow[b]{a} B \xleftrightarrow[bbb]{a} C \\
\xleftrightarrow[\text{yy}]{\text{xxx}} \\
\xrightarrow[\text{letters}]{x>0} A \longleftrightarrow Z \\
\end{gather}
```

Arrows of the
extarrows package

Another arrow package is extarrows by Kỳ-Anh Huỳnh. Besides the commands `\xLefttrightarrow` \Leftrightarrow and `\xleftrightarrow` \leftrightarrow also offered by mathtools, it provides several extensible arrows whose names start with `\xlong...`. These are `\xLongleftarrow` \Longleftarrow , `\xLongrightarrow` \Longrightarrow , `\xlongleftarrow` \leftarrow , `\xlonglefttrightarrow` \longleftrightarrow , `\xlongrightarrow` \rightarrow , and `\xlongequal` $=$.

On its own the “long equal” looks like a normal equal sign, $=$, but if it has material above or below, then it grows appropriately. In contrast, the minimal length of the other “long” arrows is noticeable longer than that of their counterparts `\xrightarrow`, etc., as shown in the next example:

$$\begin{aligned} A &\overset{+12}{\underset{\text{characters}}{\rightrightarrows}} M \overset{\text{more}}{\underset{\text{characters}}{\rightrightarrows}} Z & (1) \\ 0 &\overset{x}{\rightarrow} \epsilon \overset{x}{\rightarrow} 1 & (2) \\ \overset{1}{\leftarrow} \overset{2}{\rightrightarrows} \overset{3}{\leftarrow} \overset{4}{\rightarrow} \overset{5}{\leftarrow} & (3) \end{aligned}$$

```
\usepackage{mathtools,extarrows}
\begin{gather}
A \xlongequal[\text{characters}]{+12} M \xlongequal[\text{characters}]{\text{more}} Z \\
0 \xrightarrow{x} \epsilon \xrightarrow{x} 1 \\
\longleftarrow[1] \longrightarrow[2] \longleftarrow[3] \longrightarrow[4] \longleftarrow[5]
\end{gather}
```

11-4-3

11.4.2 Fractions and their generalizations

In addition to the `\frac` command from standard L^AT_EX, the amsmath package provides `\dfrac` and `\tfrac` as convenient abbreviations for `{\displaystyle \frac ...}` and `{\textstyle \frac ...}` (mathematical styles are discussed in more detail in Section 11.7.1 on page 195).

$$\begin{aligned} &\frac{1}{k} \log_2 c(f) \quad \frac{1}{k} \log_2 c(f) & (1) \\ \text{Text: } &\sqrt{\frac{1}{k} \log_2 c(f)} \quad \sqrt{\frac{1}{k} \log_2 c(f)}. \end{aligned}$$

```
\usepackage{amsmath}
\begin{equation} \frac{1}{k} \log_2 c(f) \quad \tfrac{1}{k} \log_2 c(f) \\
\end{equation}
Text: $ \sqrt{\frac{1}{k} \log_2 c(f)} \quad \sqrt{\frac{1}{k} \log_2 c(f)} $.
```

11-4-4

For binomial coefficients such as $\binom{n}{k}$, use the corresponding commands `\binom`, `\dbinom`, and `\tbinom`.

$$\begin{aligned} &\binom{k}{2} 2^{k-1} + \binom{k-1}{2} 2^{k-2} & (1) \\ \text{Text: } &\binom{k}{2} 2^{k-1} + \binom{k-1}{2} 2^{k-2}. \end{aligned}$$

```
\usepackage{amsmath}
\begin{equation} \binom{k}{2} 2^{k-1} + \tbinom{k-1}{2} 2^{k-2} \\
\end{equation}
Text: $ \binom{k}{2} 2^{k-1} + \dbinom{k-1}{2} 2^{k-2} $.
```

11-4-5

All of these `\binom` and `\frac` commands are special cases of the generalized fraction command `\genfrac`, which has six parameters.

Style	Default Thickness (approximately)
text/display	0.40pt
script	0.34pt
scriptscript	0.24pt

Table 11.2: Default rule thickness in different math styles

$$\backslash\mathrm{genfrac}\{ldelim\}\{rdelim\}\{thick\}\{style\}\{num\}\{denom\}$$

The first two parameters, *ldelim* and *rdelim*, are the left and right delimiters, respectively. They must be either both empty or both nonempty; to place a single delimiter, use a period “.” on the “empty” side. The third parameter, *thick*, is used to override the default thickness of the fraction rule; for instance, `\binom` uses 0pt for this argument so that the line is invisible. If it is left empty, the line thickness has the default value specified by the font setup in use for mathematical typesetting. The examples in this chapter use the defaults listed in Table 11.2 in the various styles (see also Section 11.7.1).

The fourth parameter, *style*, provides a “mathematical style override” for the layout and font sizes used. It can take integer values in the range 0–3 denoting `\displaystyle`, `\textstyle`, `\scriptstyle`, and `\scriptscriptstyle`, respectively. If this argument is left empty, then the style is selected according to the normal rules for fractions (described in Table 11.7 on page 195). The last two arguments are simply the numerator (*num*) and denominator (*denom*).

To illustrate, here is how `\frac`, `\tfrac`, and `\binom` might be defined:

```
\newcommand\frac [2]{\genfrac{}{}{}{}{#1}{#2}}
\newcommand\tfrac [2]{\genfrac{}{}{}{1}{#1}{#2}}
\newcommand\binom [2]{\genfrac{()}{()}{0pt}{}{#1}{#2}}
```

Of course, if you want to use a particular complex notation (such as one implemented with `\genfrac`) repeatedly throughout your document, then you can do yourself (and your editor) a favor if you define a meaningful command name with `\newcommand` as an abbreviation for that notation, as in the examples above.

The old generalized fraction commands `\over`, `\overwithdelims`, `\atop`, `\atopwithdelims`, `\above`, and `\abovewithdelims` (inherited in standard L^AT_EX from plain T_EX) produce warning messages if they are used with the `amsmath` package.

Sometimes the numerator or the denominator is very large, and in such cases it would be nice to be able to split them over two lines. This is made possible by the following two commands offered by `mathtools`:

[mathtools additions to amsmath](#)

$$\backslash\mathrm{splitfrac}\{start\}\{continuation\} \quad \backslash\mathrm{splitdfrac}\{start\}\{continuation\}$$

Both commands typeset the two lines in `\textstyle` (despite the “d” in the name), but `\splitdfrac` spreads them wider apart. The difference is clearly visible in the

next example. Nesting is possible, but you may have to add a `\mathstrut` to achieve even spacing in all lines.

```
\usepackage{mathtools}
\[ A = \frac{\splitfrac{a + b + c + d}{+ e + f + \sum_i x_i}}{\alpha}
\sim \frac{\splitdfrac{a + b + c + d}{+ e + f + \sum_i x_i}}{\beta}
< \frac{\omega}{\frac{\splitfrac{z - y - x - w - v - u}{- t - s - r - q}
{\splitfrac{\mathstrut - p - o - n - m}}}} \]
```

$$A = \frac{a+b+c+d}{\alpha} \simeq \frac{a+b+c+d}{\beta} < \frac{\omega}{\frac{z-y-x-w-v-u}{-t-s-r-q} - p-o-n-m}$$

11-4-6

11.4.3 Continued fractions

The `\cfrac` command produces fraction arrays known as “continued fractions”. By default, each numerator formula is centered; left or right alignment of a numerator is achieved by adding the optional argument `[l]` or `[r]`.

$$\sqrt{2} + \frac{1}{\sqrt{3} + \frac{1}{\sqrt{4} + \frac{1}{\sqrt{5} + \frac{1}{\sqrt{6} + \dots}}}}$$

```
\usepackage{amsmath}
\begin{equation*}
\cfrac{1}{\sqrt{2}} +
\cfrac{1}{\sqrt{3}} +
\cfrac{1}{\sqrt{4}} +
\cfrac[r]{1}{\sqrt{5}} +
\cfrac[l]{1}{\sqrt{6}} + \dotsb
\end{equation*}
```

11-4-7

11.4.4 Limiting positions

Subscripts and superscripts on integrals, sums, or other operators can be placed either above and below the mathematical operator or in the normal sub/super positions on the right of the operator. They are said to “take limits” if the superscript and subscript material is placed (in the “limit positions”) above and below the symbol or operator name. Typically, no limits are used in text (to avoid spreading lines apart); in a display, the placement depends on the operator used. The default placements in \LaTeX are illustrated in the following example:

$$\sum_{i=1}^n \int_0^\infty \lim_{n \rightarrow 0}$$

Text: $\sum_{i=1}^n, \int_0^\infty, \lim_{n \rightarrow 0}$.

```
\[
\sum_{i=1}^n \quad \int_0^\infty \quad \lim_{n \rightarrow 0}
\]
```

Text: $\sum_{i=1}^n$, \int_0^∞ , $\lim_{n \rightarrow 0}$.

11-4-8

The placement of subscripts and superscripts on integrals, sums, and other operators is often dictated by the house style of a journal. Recognizing this fact, `amsmath` offers a long list of options for controlling the positioning. In the following summary, *default* indicates what happens when the `amsmath` package is used with a standard \LaTeX class but without any of these options.¹

amsmath options
to control subscript
and superscript
placements

intlimits, nointlimits In displayed equations only, place superscripts and subscripts of integration-type symbols above and below or at the side (default), respectively.

sumlimits, nosumlimits In displayed equations only, place superscripts and subscripts of summation-type symbols (also called “large operators”) above and below (default) or at the side, respectively.

These options also affect other big operators — \prod , \coprod , \otimes , \oplus , and so forth — but not integrals.

namelimits, nonamelimits Like **sumlimits** or **nosumlimits** but for certain “operator names”, such as **det**, **inf**, **lim**, and **max**, **min**, that traditionally have subscripts placed underneath, at least when they occur in a displayed equation.

The positioning on individual symbols/names can be controlled directly by placing one of the following TeX primitive commands immediately after the symbol or operator name: `\limits`, `\nolimits`, or `\displaylimits`. This last command, which specifies that the operator “takes limits” only when the mathematical style is a display style, is the default whenever a symbol of class Operator² appears or a `\mathop` construction is used. If an operator is to “take limits” outside a display, then this must be declared individually using the `\limits` command. Compare the next example to Example 11-4-8, noting that some commands show no effect as they merely reinforce the default.

11-4-9

$$\sum_{i=1}^n \int_0^\infty \lim_{n \rightarrow 0}$$

Text: $\sum_{i=1}^n, \int_0^{\infty}, \lim_{n \rightarrow 0}$.

[illegible]

11.4.5 Stacking in subscripts and superscripts

The standard `\substack` command is most commonly used to typeset several lines within a subscript or superscript, using `\\` as the row delimiter.

A slightly more general structure is the `subarray` environment provided by the `amsmath` package, which allows you to specify that the lines should be left

¹But not necessarily when using the $\mathcal{A}_{\mathcal{M}\mathcal{S}}\text{-}\text{\LaTeX}$ document classes.

²See Section 11.8.1 on page 209 for a discussion of the various mathematical classes of symbols.

aligned instead of centered (no right alignment). Note that both structures need to be surrounded by braces when they appear as a subscript or superscript.

$\sum_{\substack{0 \leq i \leq m \\ 0 < j < n}} P(i, j) \quad (1)$	$\sum_{\substack{i \in \Lambda \\ 0 \leq i \leq m \\ 0 < j < n}} P(i, j) \quad (2)$	<pre> \usepackage{amsmath} \begin{gather} \sum_{\substack{0 \leq i \leq m \\ 0 < j < n}} P(i, j) \\ \sum_{\substack{i \in \Lambda \\ 0 \leq i \leq m \\ 0 < j < n}} P(i, j) \end{gather} </pre>	<div style="border: 1px solid black; padding: 2px; display: inline-block;">11-4-10</div>
--	---	---	--

*mathtools additions
to amsmath*

If your `\subarray` or your `\substack` involves sub or superscripts, you should consider using the cramped versions offered by `mathtools`. Without it the superscripts are raised too much, and while the difference is small, it is noticeable. Compare the product on the left and the right with that in the middle in the next example:

$\prod_{a^2 < c} \prod_{\substack{a^2 < c \\ c < 1}} \prod_{\substack{a^2 < c \\ c < 1}}$	<pre> \usepackage{mathtools} \[\prod_{a^2 < c} \quad \quad \quad \prod_{\substack{a^2 < c \\ c < 1}} \quad \quad \quad \prod_{\crampedsubarray{1}{a^2 < c \\ c < 1}} \quad \quad \quad \] </pre>	<div style="border: 1px solid black; padding: 2px; display: inline-block;">11-4-11</div>
---	--	--

11.4.6 amsmath, esint, wasysym — Multiple integral signs

Using `amsmath`, the commands `\iint`, `\iiint`, and `\iiiiiint` give multiple integral signs with well-adjusted spaces between them, in both running text and displays. The command `\idotsint` gives two integral signs with ellipsis dots between them. These commands are all built up from single integrals placed side by side (with somewhat reduced spacing), whereas the `esint` package (described below) uses a separate symbol font with individual glyphs for each integral.

The following example also shows the use of `\limits` to override the default for integral constructions and place the limit V underneath the symbol; as an alternative, we could have used the package option `intlimits`.

$\iint_V \mu(v, w) \, du \, dv$ $\iiint_V \mu(u, v, w) \, du \, dv \, dw$ $\iiiiiint_V \mu(t, u, v, w) \, dt \, du \, dv \, dw$ $\int \cdots \int_V \mu(z_1, \dots, z_k) \, \mathbf{dz}$	<pre> \usepackage{amsmath} \begin{gather*} \iint\limits_V \mu(v, w) \quad \quad \quad \, du \, \, dv \\ \iiint\limits_V \mu(u, v, w) \quad \quad \quad \, du \, \, dv \, \, dw \\ \iiiiiint\limits_V \mu(t, u, v, w) \quad \quad \quad \, dt \, \, du \, \, dv \, \, dw \\ \idotsint\limits_V \mu(z_1, \dots, z_k) \quad \quad \quad \, \mathbf{dz} \end{gather*} </pre>	<div style="border: 1px solid black; padding: 2px; display: inline-block;">11-4-12</div>
--	--	--

Do not try to apply superscripts to these integrals when setting them with `\limits`; they come out in fairly strange places as the next example shows. This time we used `intlimits` so that all integrals have limits by default.

11-4-13

$$\int_a^b \int_a^b \int_a^b \int_a^b \int_a^b \int_a^b \dots \int_a^b$$

```
\usepackage[intlimits]{amsmath}
\begin{gather*}
\int_a^b \quad \iint_a^b \quad \iiint_a^b \quad \iiint_a^b \quad \oint_a^b \quad \idotsint_a^b
\end{gather*}
```

If you think that the `amsmath` versions of the multiple integral signs are too much spaced apart or if you need other integral signs that are not in that set, you can load the `esint` package by Eddie Soudrais. Like `amsmath` it supports the options `intlimits` and `nointlimits` (default). If both packages are used, `amsmath` has to be loaded first; otherwise, it reinstalls its version of the integrals, and only the new ones are available.

If you compare the first line of the next example with the previous one, you can see that the individual integrals are much closer together and that with the `esint` package version the upper limits, though not perfect, come out more or less right. The second and third rows show the additionally defined integrals by the package, in case you have a need for one or the other in that set. Again, we use the option `intllimits` and override it a few times with an explicit `\nolimits` command.

11-4-14

$\overset{b}{f}_a$
 $\overset{b}{ff}_a$
 $\overset{b}{fff}_a$
 $\overset{b}{ffff}_a$
 $\overset{b}{f\circ}_a$
 $\overset{b}{f\cdots}_a$

$\overset{b}{f\circ}_a$
 $\overset{b}{f\circ}_a$
 $\overset{b}{f\Box}_a$
 $\overset{b}{ff\Box}_a$
 $\overset{b}{f\curvearrowright}_a$
 $\overset{b}{f\curvearrowright}_a$

$\overset{b}{f\circ}_a$
 $\overset{b}{f\circ}_a$
 $\overset{b}{f\circ}_a$
 $\overset{b}{f\circ}_a$
 $\overset{b}{f}_a$

[illegible]

As the package uses its own symbol font, it should be used only if you use the default Computer Modern Math fonts or a set of math fonts that are visually compatible with these integrals.

Some people prefer upright integral symbols instead of the default slanted ones. This can be achieved using the package `wasysym` with the option `integrals`. If `amsmath` is loaded too (order is irrelevant), then `\iiint` and `\idotsint` are also changed; otherwise, these two `amsmath` commands are not available. The other

*Upright integrals
with wasysym*

special integrals provided by the `esint` package are not available in this style. See Section 10.13.2 on page 116 for further information on the `wasysym` package.

$$\int_a^b \iint_a^b \iiint_V \iiint_V$$

$$\oint_a^b \oiint_a^b \int \cdots \int_V$$

```
\usepackage[integrals]{wasysym} \usepackage{amsmath}
\begin{gather*}
\int\limits_a^b \quad \iint\limits_a^b \quad \iiint\limits_V \quad \iiint\limits_V \\
\oint\limits_a^b \quad \oiint\limits_a^b \quad \int \cdots \int_V \\
\idotsint\limits_V
\end{gather*}
```

11-4-15

11.4.7 diffcoeff — Handling derivatives of arbitrary order

If you often need ordinary, partial, and other derivatives, then take a look at the `diffcoeff` package by Andrew Parsloe, because it helps you to produce them in a consistent manner with the ability to adjust their style in various ways. By default, it implements the ISO 80000-2 recommendation, and with the help of a `def-file` option you can specify a file to hold your own conventions and adjustments for reuse in several documents.

```
\diff**[order]{differentiand}{variable of differentiation}[evaluated at]
```

The command `\diff` produces an ordinary derivative, while `\diffp` is responsible for partial derivatives — the argument structure is the same for both commands. The `differentiand` is normally set as a numerator; the starred form appends it instead, and a second star also swaps the mandatory arguments — i.e., *variable* first, to retain the reading order. If you prefer a slashed style use `\difs` or `\difsp`, and for a very compact representation, use `\difc` or `\difcp` instead. The *order* of differentiation (default 1) is specified in the first optional argument, and a point of evaluation can be set in the second optional argument. Below we show a few examples:

$$\left(\frac{d^2 \ln \sin x}{d(\sin x)^2} \right)_\pi \quad \frac{\partial^{n+1} F}{\partial x^{n+1}} \quad \frac{d}{dx} (ax^2 + bx + c)$$

```
\usepackage{diffcoeff}
\[\diff[2]{\ln\sin x}{\sin x}[\pi] \quad \diffp[n+1]{F}{x} \quad \diff*{(ax^2+bx+c)}{x} \quad \backslash]
```

11-4-16

If you prefer to have fewer braces in your formula, you can leave them out around the mandatory arguments — but, of course, only if they are single tokens! We have done this in the next example, which uses slashed and compact style, because this usually works better in text. Otherwise, this repeats the previous example to allow for easy comparison.

$$\left(\frac{d^2 \ln \sin x}{d(\sin x)^2} \right)_\pi \text{ and } \partial^{n+1} F / \partial x^{n+1} \text{ and } (d/dx)(ax^2 + bx + c)$$

$$\left(\frac{d^2_{\sin x} \ln \sin x}{d_{\sin x}} \right)_\pi \text{ and } d_x^{n+1} F \text{ and } d_x(ax^2 + bx + c)$$

```
\usepackage{diffcoeff}
$\difs[2]{\ln\sin x}{\sin x}[\pi]$ and
$\difsp[n+1] Fx$ and $\difs*{(ax^2+bx+c)}x$
$difc[2]{\ln\sin x}{\sin x}[\pi]$ and
$difcp[n+1] Fx$ and $difc*{(ax^2+bx+c)}x$
```

11-4-17

Notations like dx or $\mathrm{d}x$ (ISO style) also appear in other places than derivatives, e.g., in integrals. If you switch between different styles (because the publishing journal has requirements to use or not use ISO style), you would want to see the expressions change throughout without the need to manually alter the source. To accomodate this, the package offers the small command `\dl`, which changes appearance based on the overall style you have selected. By default, the d 's are written upright:

11-4-18

$$\mathrm{d}P = \frac{\partial P}{\partial x} \mathrm{d}x + \frac{\partial P}{\partial y} \mathrm{d}y + \frac{\partial P}{\partial z} \mathrm{d}z$$

```
\usepackage{diffcoeff}
\[ \dl P = \diffp Px \dl x + \diffp Py \dl y
    + \diffp Pz \dl z
\]
```

The package offers many customization possibilities. You can, for example, produce derivatives with symbols such as D , δ , or Δ ; adjust the spacing; define new variants; and much more. For reuse in different documents, the necessary declarations can be stored in a file with the extension `.def` and loaded with the option `def-file=<file>`. See the extensive package documentation for further details.

11.4.8 Modular relations

Standard \LaTeX already provides the commands `\bmod` and `\pmod`. The `amsmath` package augments this set with `\mod` and `\pod` to deal with special spacing conventions of the “mod” notation for equivalence classes of integers. These extra commands are variants of `\pmod` that are preferred by some authors; `\mod` omits the parentheses, whereas `\pod` omits the “mod” and retains the parentheses. Furthermore, with `amsmath` the spacing of `\pmod` is decreased within an inline formula.

11-4-19

$$\begin{aligned} u &\equiv v + 1 \mod n^2 \\ u &\equiv v + 1 \bmod n^2 \\ u &= v + 1 \pmod{n^2} \\ u &= v + 1 \pod{n^2} \end{aligned}$$

The in-text layout: $u = v + 1 \pmod{n^2}$

$$\begin{aligned} k^2 &= (m \bmod n); & x &\equiv y \pmod{b}; \\ x &\equiv y \mod c; & x &\equiv y \pod{d}. \end{aligned}$$

```
\usepackage{amsmath}
\begin{align*}
u &\equiv v + 1 \mod{n^2} && \\
u &\equiv v + 1 \bmod{n^2} && \\
u &= v + 1 \pmod{n^2} && \\
u &= v + 1 \pod{n^2} && \end{align*}
The in-text layout: $ u = v + 1 \pmod{n^2} $
\begin{align*}
k^2 &= (m \bmod n) && \backslash, ; & \\
x &\equiv y \pmod{b} && \backslash, ; & \\
x &\equiv y \mod{c} && \backslash, ; & \\
x &\equiv y \pod{d} && \backslash, . & \end{align*}
```

11.4.9 mathtools, interval — Properly spaced intervals

Specifying intervals is usually done by using brackets as fences, e.g., “[a, b]”. This is simple for closed intervals, but the natural input for open or half-open intervals fails rather miserably with respect to spacing as seen in the next example:

11-4-20

$$[a, e[= [a, b] +]b, c[+]c, d[- [d, e[\quad \$ \quad [a, e[= [a, b] +]b, c[+]c, d[- [d, e[\quad \$$$

The reason for this spacing result is that “[” is considered by T_EX as an opening and “]” as a closing symbol. However, if used as fences for half or fully open intervals, their interpretation should be reversed — something T_EX cannot determine by itself. So it sees an opening symbol “[” followed by an “=” (relation), and that does not get any space added. With the help of explicit `\mathopen` and `\mathclose` commands (see Section 11.8.1 on page 209), this can be corrected; however, the resulting input becomes rather noncomprehensible at the same time:

$$[a, d[= [a, b] +]b, c[+]c, d[- [d, e[\quad \$ [a, d\mathclose{} = [a, b] + \mathopen{}b, c[+ \mathopen{}c, d\mathclose{} - [d, e\mathclose{} \$ \quad 11-4-21$$

*mathtools addition
to amsmath*

To avoid such source code monsters, `mathtools` offers the possibility of defining new commands that automatically supply opening and closing delimiters around their argument.

```
\DeclarePairedDelimiter{cmd}{left-delimiter}{right-delimiter}
```

This declaration defines a new command `cmd` with one mandatory argument that is typeset surrounded by the *left-delimiter* and *right-delimiter*. Also defined is a starred form that sets the delimiters using `\left` and `\right`, which is why you can use only real delimiters that are allowed after those commands, e.g., those from Table 11.5 on page 190 or Table 11.30 on page 224. Instead of the star, you can use an optional argument to specify the size explicitly using `\big`, `\Big`, `\bigg`, or `\Bigg`.

$$[a, d[= [a, b] +]b, c[+ \dots \quad \left[\frac{a}{b} \approx \right] \frac{a}{b} \left[\neq \right] x \quad \begin{array}{l} \text{\textcolor{blue}{\code{\usepackage{mathtools} \DeclarePairedDelimiter\closed{[]{}}}}} \\ \text{\textcolor{blue}{\code{\DeclarePairedDelimiter\open{[]}{}} \code{\DeclarePairedDelimiter\ropen{[]{}}}}} \\ \text{\textcolor{blue}{\code{\DeclarePairedDelimiter\lopen{[]{}}}}} \\ \text{\code{\begin{gather*}}} \\ \text{\code{\ropen{a,d}=\closed{a,b} + \lopen{b,c} + \dotsb \ll[3pt}} \\ \text{\code{\lopen{\frac{a}{b}}}} \text{\code{\approx}} \text{\code{\lopen*{\frac{a}{b}}}} \\ \text{\code{\neq}} \text{\code{\closed[\Bigg]{x}}} \\ \text{\code{\end{gather*}}}} \end{array} \quad 11-4-22$$

*The interval
approach*

An alternative specifically for intervals is provided by Lars Madsen with the package `interval`. It allows you to input intervals as logical constructs and takes care of the correct formatting in the background.

```
\interval[key/value-list]{left}{right}
```

The two mandatory arguments are the *left* and *right* boundaries of the interval, and with the *key/value-list* you specify the type and possibly some formatting features. The `\interval` command then selects the appropriate fences, selects the separator symbol, and ensures appropriate spacing.

$$[a, d[= [a, b] +]b, c[+]c, e[- [d, e[\quad \begin{array}{l} \text{\textcolor{blue}{\code{\usepackage{interval}}}} \\ \text{\code{\[\interval[open right]{a}{d} = \interval{a}{b} +}} \\ \text{\code{\interval[open left]{b}{c} + \interval[open]{c}{e}}} \\ \text{\code{- \interval[open right]{d}{e}}} \text{\code{\]} } \end{array} \quad 11-4-23$$

Beside the various `open...` keys shown above, you can use the key `scaled`, which scales the fences to automatically match the height of the content. It can alternatively be used with a value (such as `\Big`), in which case that determines the size of the fences. A (nonsense) example is shown in Example 11-4-24.

```
\ointerval[key/value-list]{left}{right}
\linterval[key/value-list]{left}{right}
\rinterval[key/value-list]{left}{right}
```

As the keywords are rather verbose, there are also three shorthands for the most common cases: open and half-open intervals. Scaling or other keys can still be set in the *key/value-list* argument. This is also shown in the next example.

```
\intervalconfig{key/value-list}
```

Some people prefer a semicolon or two periods as the separator between the boundaries instead of a comma. Also quite common is to use parentheses instead of brackets for the open fences (called *soft fences*). All this and more can be specified in the argument to `\intervalconfig` as exhibited below:

11-4-24

$$\left[a..d \right] = \left[a..b \right] + \left(b..c \right) + \left(c..e \right) - \left[d..e \right]$$

```
\usepackage{color,interval}
\intervalconfig{soft open fences,separator symbol=.,
               colorize=\color{blue}}

\l
\rinterval{a}{d} = \interval{a}{b} +
\linterval{b}{c} + \ointerval{c}{e}
- \rinterval[scaled=\Big]{d}{e}

\]
```

Colorizing all intervals is normally not useful, but it can help if you change an existing document to use the interval package. You can then easily check if all intervals have been properly converted to the new syntax.

11.4.10 `braket` — Dirac bra-ket and set notation

The bra-ket notation, also known as Dirac notation, was established by Paul Dirac around 1940. In quantum mechanics it is a common notation for describing quantum states. Donald Arseneau produced a small package, `bracket`, that offers a handful of commands to enter the notation consistently.

```
\bra{formula}   \ket{formula}   \braket{formula}   \set{formula}
\Bra{formula}   \Ket{formula}   \Braket{formula}   \Set{formula}
```

Commands starting with an uppercase letter grow vertically to enclose their content (using internally `\left` and `\right`), while the lowercase commands do not change sizes. You can use `|` in the argument to generate extensible vertical lines as needed,

and with `||` or `\|` you get doubled lines. As sets have a similar structure involving vertical lines, they are also provided via `\set` and `\Set`.

$ \psi\rangle\langle\phi : \xi\rangle \mapsto \psi\rangle\langle\psi \xi\rangle$ $\left\langle\phi\left \frac{\partial^2}{\partial t^2}\right \psi\right\rangle$ <p>Also:</p> $\{x \in \mathbb{R}^2 \mid 0 < x < 5\}$	<pre>\usepackage{mathtools,braket} \begin{gather*} \ket{\psi}\bra{\phi} : \ket{\xi} \mapsto \ket{\psi}\braket{\psi \xi} \Braket{\phi \frac{\partial^2}{\partial t^2} \psi} \shortintertext{Also:} \Set{x\in \Re^2 \mid 0 < x < 5} \end{gather*}</pre>	11-4-25
--	---	---------

11.4.11 amsmath, mathtools, empheq — Boxed formulas

The `amsmath` command `\boxed` puts a box around its argument; it works just like `\fbox`, except that the contents are in math mode.

$W_t - F \subseteq V(P_i) \subseteq W_t \quad (1)$	<pre>\usepackage{amsmath} \begin{equation} \boxed{W_t - F \subseteq V(P_i) \subseteq W_t} \end{equation}</pre>	11-4-26
--	--	---------

*mathtools addition
to amsmath*

The `mathtools` package extends this approach with the command `\Aboxed`. This command can be used to produce a boxed formula across an alignment point (`&`) in math display environments such as `align`. Do not use it when there is no alignment point to cross, e.g., in the second equation in the example, because it would generate an error in that case.

$f(x) = \int h(x) dx \quad (1)$	<pre>\usepackage{mathtools} \begin{align} \Aboxed{f(x) = \int h(x) dx} \\ &= \boxed{g(x)} \quad (2) \end{align}</pre>	11-4-27
---------------------------------	---	---------

*Annotating
amsmath
environments with
empheq*

A much more general approach is taken by the package `empheq` by Morten Høgholm and Lars Madsen. In essence it offers a wrapper environment for most of the `amsmath` environments so that you can specify special extra formatting, such as (colored) boxes or adding something to the left or right of the formula, regardless of whether or not there are equation numbers. The general syntax is the following:

```
\begin{empheq}[key/value list]{amsmath-env}
... contents of the amsmath environment ...
\end{empheq}
```

In the `amsmath-env` argument you specify the name of one of the `amsmath` display environments from Sections 11.2.2 to 11.2.7 on pages 133–138. Not supported are the “boxed” environments, i.e., `aligned`, `gathered`, etc.

If used without the optional *key/value list*, this should produce identical output compared to using the `amsmath` environment directly, though with a few restrictions. It is not possible to use `\intertext` or `\displaybreak` because the `empheq` environment puts the display into unbreakable boxes to attach extra material. For the same reason, the automatic movement of the equation tag if the display is too wide no longer works, and you have to make any necessary adjustments manually.

In the *key/value list* you can specify a number of keys to annotate your formula; the next example shows the most important ones, though normally you will not use all of them at the same time.

With `box` you specify a box command, e.g., `\fbox`, that is applied to the whole display formula excluding the equation tags but including any `left` or `right` annotation if also given. The `innerbox` key does the same but applies only to the formula itself. There is also a `marginbox` key (not shown) for special effects when equations are set flushed left (`fleqn` option in force).

11-4-28

$$\left\{ \begin{array}{ll} x_0 = 1 & x_1 = 2 \\ x_2 = 3 & x_3 = 5 \\ x_4 = 8 & x_5 = 13 \\ x_6 = 21 & x_7 = 34 \\ \dots & \sum_{i=1}^n x_i = ?? \end{array} \right.$$

```
(1) \usepackage{empheq,xcolor}
(2) \begin{empheq}[box=\fcolorbox{black}{blue!10},
(3)   innerbox=\colorbox{white},
(4)   left=\longrightarrow \empheqlbrace,
(*)  right=\empheqbigbrack \Longrightarrow]{align}
    x_0&=1 & x_1&=2 & \\
    x_2&=3 & x_3&=5 & \\
    x_4&=8 & x_5&=13 & \\
    x_6&=21 & x_7&=34 & \\
    & \ldots & \sum_{i=1}^n x_i & \\
    & & & \tag{*}
\end{empheq}
```

The use of `left` and `right` keys in the previous example shows some package-specific commands: `\empheqlbrace` and `\empheqbigbrack`. As one can see, they produce vertically extensible braces matching (or slightly exceeding) the `innerbox` height. If we had used `\lbrace` and `\rbrace`, we would have gotten nonextensible braces, but we could, of course, have used both `\left` and `\right` to scale them with a similar result to `\empheqbig..` as we did. Several other delimiters are available by preceding their name with `empheq` or `empheqbig`, for example, `\empheqlparen` or `\empheqrangle`; the full list of supported delimiter names is angle “`<`”, brace “`{`”, brack “`[`”, ceil “`|`”, floor “`|`”, paren “`(`”, vert “`|`”, and Vert “`|`”.

You might wonder why the *key/value list* is optional, given that there is no obvious reason to use the environment at all if that argument is not supplied. The reason is the package option `overload`: If you load the package with that option, then the `amsmath` environments are all redefined to use `empheq` internally; e.g., you can then write `\begin{align}[box...]=` instead of the code shown in Example 11-4-28.

The original environments are still available if needed, e.g., if you want to use `\intertext` or `\displaybreak`. All you have to do is to prefix the original name with `AmS`; thus, `AmSalign` will be `amsmath`’s original `align` environment, etc.

11.4.12 amsmath, accents, mathdots — Various accents

T_EX distinguishes sharply between accented characters in text and in math. To obtain “à” in text, you can use the Unicode character “à” or the command “\‘a”, both of which fail in math mode. Depending on the engine you might get a warning or error message, but the character may also be silently ignored with only an entry in the transcript file saying something like

Missing character: There is no à in font lmmi10!

Thus, to typeset accents over mathematical symbols you should always use special math accent commands, i.e., \grave in this case. The full set of math accents provided by standard L^AT_EX is shown in the next example.

Note that most accents change with the math alphabet currently in use; e.g., all but \vec, \widehat, and \widetilde become bold when we place them inside \mathbf. This means you have a choice: if you use \hat or any other varying math accent within a math alphabet command, you get accents in the “style” of the alphabet; if you use them outside, you get ordinary ones. This is shown on the third line.

$\grave{x} \ \grave{x} \ \grave{x} \ \grave{x} \ \grave{x} \ \grave{x} \ \grave{x} \ \grave{x} \ \grave{x} \ \grave{x}$ $\grave{y} \ \grave{y} \ \grave{y} \ \grave{y} \ \grave{y} \ \grave{y} \ \grave{y} \ \grave{y} \ \grave{y} \ \grave{y}$ $\hat{C} \simeq \hat{C}$	<pre>\newcommand\accsample[1]{\dot{#1} \; \; \ddot{#1} \; \; \mathring{#1} \; \; \acute{#1} \; \; \grave{#1} \; \; \hat{#1} \; \; \check{#1} \; \; \breve{#1} \; \; \bar{#1} \; \; \tilde{#1} \quad \quad \vec{#1} \; \; \widehat{#1} \; \; \widetilde{#1}} \[\ \accsample{x} \] \[\ \mathbf{\accsample{y}} \] \[\ \hat{\mathbf{C}} \] \simeq \mathbf{\hat{C}} \]</pre>	11-4-29
--	---	---------

Be careful with
accents inside
math alphabets

However, the fact that many math accents vary inside math alphabets has a downside: if they are lacking accents, then you get whatever is in the font at the position T_EX believes the accent is stored. For example, the \mathcal alphabet is part of the standard symbol font, which contains no accents. Thus, using math accents that vary inside \mathcal gives you very strange results (without a warning).

As shown in the first line of the example, only the three nonchanging accents come out right here. The remedy in that case is to use \mathcal only for your base letter and the accent command outside to get the normal math accent, as shown in the second line.

$\mathcal{A} \mathcal{A} \mathcal{A} \mathcal{A} \mathcal{A} \mathcal{A} \mathcal{A} \mathcal{A} \mathcal{A} \mathcal{A}$ $\mathcal{B} \mathcal{B} \mathcal{B} \mathcal{B} \mathcal{B} \mathcal{B} \mathcal{B} \mathcal{B} \mathcal{B} \mathcal{B}$	<pre>% \accsample as previously defined \[\ \mathcal{\accsample{A}} \] \[\ \accsample{\mathcal{B}} \]</pre>	11-4-30
--	---	---------

More dot accents
with amsmath

The \dot and \ddot mathematical accents from standard L^AT_EX are supplemented in amsmath by \dddots and \ddddots, giving triple and quadruple dot accents, respectively.

$\dot{S} \quad \ddot{P} \quad \ddot{Q} \quad \ddot{R}$	<pre>\usepackage{amsmath} \$\dot{S} \quad \ddot{P} \quad \ddot{Q} \quad \ddot{R}\$</pre>	11-4-31
--	--	---------

... mathdots ...

There are also refined versions provided by the mathdots package if loaded in

addition to amsmath. They use slightly tighter spacing between the dots.

11-4-32

$$\dot{S} \quad \ddot{P} \quad \overset{\cdot\cdot\cdot}{Q} \quad \overset{\cdot\cdot\cdot\cdot}{R}$$

```
\usepackage{amsmath,mathtools}
```

$$\dot{S} \quad \ddot{P} \quad \dddot{Q} \quad \ddddot{R}$$

Even tighter spacing is used by the accents package:

... *and* accents

11-4-33

$$\dot{S} \quad \ddot{P} \quad \overset{\cdot\cdot\cdot}{Q} \quad \overset{\cdot\cdot\cdot\cdot}{R}$$

```
\usepackage{amsmath,accents}
```

$$\dot{S} \quad \quad \ddot{P} \quad \quad \dddot{Q} \quad \quad \dddot{R}$$

If you want to set up your own mathematical accents, then you should probably use the accents package developed by Javier Bezos. It provides methods of defining “faked” accents (see `\accentset` in the example) and general under-accents (`\underaccent`, `\undertilde`), along with other features. It can be used together with `amsmath` as shown in the previous example but has to be loaded after it. We give two examples of its possibilities; for further details see [17].

... and also many additional accents with accents

11-4-34

$$X \quad \overset{\wedge}{\underset{\wedge}{h}} \quad \underset{\diamond}{\mathcal{M}} \quad \underset{\sim}{C} \quad \underset{\sim}{M} \quad \underset{\sim}{ABC}$$

```
\usepackage{accents}
```

[illegible]

The warning that not all accents work inside all math alphabets is equally true for the accents provided by the accents package. If that is the case, you have to ensure that the accent is outside of the math alphabet's scope.

11-4-35

$$\hat{\ast} \mathbf{h} \text{ (ok) but } \hat{\mathbb{A}} \mathcal{X} \text{ (bad) } \hat{\ast} \mathcal{X} \text{ (ok again)}$$

```
\usepackage{accents}
```

$\mathbf{\hat{\star\tilde{h}}}$ (ok) but

 $\hat{\star\tilde{X}}$ (bad)

$\hat{\star\tilde{\mathcal{X}}}$ (ok again)

When adding an accent to an i or j in mathematics, it is best to use the dotless variants `\imath` and `\jmath`; however, they always produce the same symbol. If you want them to vary based on the current math alphabet, use `\dotlessi` or `\dotlessj` provided by the `dotlessi` package written by Javier Bezos:

 Accents over the characters i or j

11-4-36

$$\hat{i} \neq \hat{i} \neq \mathbf{\hat{i}}$$

```
\usepackage{dotlessi,amsmath}
```

$$\hat{\imath} \not\leq \mathbf{\hat{\imath}} \not\leq \mathbf{\hat{\dotless i}}$$

A collection of simple commands for placing accents as superscripts to a subformula is available with the package `amsxtra`. This is not a very common layout, but it is occasionally used:

Accents as
superscripts

11-4-37

$$\begin{array}{ccc} (xyz)^{\cdots} & (xyz)^{\cdots} & (xyz)^{\cdot} \\ (xyz)^{\smile} & (xyz)^{\vee} & \\ (xyz)^{\wedge} & (xyz)^{\sim} & \end{array}$$

```
\usepackage{amsxtra}
```

$$\begin{array}{llll} \$\langle xyz \rangle \spddot \$ & \quad & \$\langle xyz \rangle \spddot \$ & \quad & \$\langle xyz \rangle \spdot \$ \quad \backslash \\ \$\langle xyz \rangle \spbreve \$ & \quad & \$\langle xyz \rangle \spcheck \$ & \quad & \backslash \\ \$\langle xyz \rangle \sphat \$ & \quad & \$\langle xyz \rangle \sptilde \$ & \quad & \end{array}$$

Type	Command	Description	Output
Physical row vector	<code>\aS[accent]{symbol}</code>	<i>arrow-symbol</i>	\vec{u}
Physical column vector	<code>\Sa[accent]{symbol}</code>	<i>symbol-arrow</i>	\vec{v}
Physical tensor	<code>\aSa[accent]{symbol}</code>	<i>arrow-symbol-arrow</i>	\vec{E}
Column vector	<code>\bS[accent]{symbol}</code>	<i>bar-symbol</i>	\bar{x}
Row vector	<code>\Sb[accent]{symbol}</code>	<i>symbol-bar</i>	\underline{y}
Tensor	<code>\bSb[accent]{symbol}</code>	<i>bar-symbol-bar</i>	\bar{R}
Tensor (mixed base)	<code>\aSb[accent]{symbol}</code>	<i>arrow-symbol-bar</i>	\vec{S}
Tensor (mixed base)	<code>\bSa[accent]{symbol}</code>	<i>bar-symbol-arrow</i>	\vec{T}
Cross-product tensor ^a	<code>\aCSa[accent]{symbol}</code>	<i>arrow-symbol-arrow</i>	$\vec{\tilde{z}}$
	<code>\bCSb[accent]{symbol}</code>	<i>bar-symbol-bar</i>	$\bar{\tilde{z}}$

^aIn the cross-product tensors the tilde is automatically added to the symbol by the command.

Table 11.3: List of matrix tensor input commands

11.4.13 mattens — Commands to typeset tensors

There exist quite a number of different notations for denoting vectors and tensors, and not surprisingly, there are a number of packages that implement an input syntax for them. For the book we selected the `mattens` package by Danie Els, because it offers a simple and very flexible interface, but if this does not appeal to you, then there are a handful of other packages on CTAN and probably in your distribution.

<code>\S[accent]{sym}</code>	<code>\aCSa*[accent]{sym}</code>	<code>\bCSb*[accent]{sym}</code>
------------------------------	----------------------------------	----------------------------------

The commands offered by the package all follow the naming scheme, where the placeholder `□` stands for either `a` (arrow), `b` (bar), or nothing (no embellishment), which gives you a total of eight commands as shown in Table 11.3. All follow the same argument structure: mandatory *symbol* and an optional (math) *accent*. The starred forms typeset the symbol as an ordinary symbol, i.e., not boldened.

There are also two cross-product tensors: `\aCSa` and `\bCSb`. The example below exhibits some of the different combinations:

$\vec{x} \neq \underline{x} \neq \hat{x} \neq \bar{X}$	(1)	<code>\usepackage{mattens}</code>
$\vec{\delta} \neq \underline{\delta} \neq \hat{\delta}$	(2)	<code>\begin{gather}</code>
$\vec{a} \cdot \vec{c} = \bar{a} \times \bar{c}$	(3)	<code>\aSb{x} \neq \aSb*{x} \neq \aSb[\hat]{x} \neq \aSb{X} \\\</code>
		<code>\bS{\delta} \neq \bS*{\delta} \neq \bS[\hat]{\delta} \\\</code>
		<code>\bCSb{a} \cdot \bS{c} = \bS{a} \times \bS{c}</code>
		<code>\end{gather}</code>

11-4-38

As you can deduce from the previous example (because `gather` is available), the package implicitly loads `amsmath`. What you also see is that with Computer Modern fonts the arrows (being very large) touch the x — with Lucida Math (as shown in the table) this is not an issue. One way to solve that is to use the package option `mathstrut`, which adds a `\mathstrut` into each tensor thereby forcing upper and lower arrows and bars farther apart. You can alternatively define your own struts using, for example, `\SetSymbStrut{\vphantom{material}}` as explained in the package documentation.

Some people prefer to show tensors and vectors in a different font instead of boldening the symbols. The next example shows how to do this with the help of `\SetSymbFont`. Note that this acts only on symbols that are affected by math alphabets; e.g., the Greek letter is not altered. For the same reason you still see the ordinary x when the starred form is used, because that suppresses special formatting.

The Computer Modern fonts do not have a bold sans serif font shape, but the Latin Modern do, so we define a math alphabet for it and use that.

11-4-39

$$\overrightarrow{\underline{x}} \neq \overrightarrow{x} \neq \overrightarrow{\underline{x}} \neq \overline{\underline{X}} \quad (1)$$

$$\overline{\delta} \neq \overline{\delta} \neq \hat{\delta} \quad (2)$$

$$\overline{\underline{a}} \cdot \overline{\underline{c}} = \overline{\underline{a}} \times \overline{\underline{c}} \quad (3)$$

```
\usepackage[mathstrut]{mattens} \SetSymbFont{\mathsf{sl}}
\DeclareMathAlphabet\mathsf{sl}{OT1}{lms}{bx}{sl}

\begin{gather}
\mathsf{aSb{x}} \neq \mathsf{aSb*{x}} \neq \mathsf{aSb[\hat]{x}} \neq \mathsf{bSa{X}} \\\
\mathsf{bS{\delta}} \neq \mathsf{bS*{\delta}} \neq \mathsf{bS[\hat]{\delta}} \\\
\mathsf{bCSb{a}} \cdot \mathsf{bS{c}} = \mathsf{bS{a}} \times \mathsf{bS{c}}
\end{gather}
```

If you find yourself always using the starred forms, because you want to supply your own formatting, you can instead load the package with the option `noformat`, which suppresses the boldening or other automatic formatting of the symbols.

11.4.14 Extra decorations for symbols

Standard \LaTeX provides `\stackrel` for placing a superscript above a Relation symbol.

A set of possibly more useful commands is provided by the `amsmath` package with the commands `\overset`, `\underset`, and `\overunderset`. They can be used to place material above and/or below any Ordinary symbol or Binary operator symbol, in addition to Relation symbols, and automatically determine the correct math type for the resulting compound symbol.

11-4-40

$$\overset{*}{X} > \underset{*}{X} \stackrel[\text{loc.}]{\text{def}} \sum_{a,b \in \mathbb{R}^*}' \overset{a}{\underset{b}{X}} = X$$

```
\usepackage{amsmath}

\[ \overset{*}{X} > \underset{*}{X}
\overunderset{\mathsf{def}}{\mathsf{loc.}}{\iff}
\sideset{}{'}\sum_{a,b \in \mathbf{R}^*}
\overset{a}{\underset{b}{X}} = X \]
```

The command `\sideset` serves a special purpose, complementary to the others: it adds decorations additional to the “normal” limits (which are set above and below) to any Operator symbol such as \sum or \prod . These are placed in the subscript and superscript positions, on both the left and right of the Operator.

the spacing varies. These defaults from the `amsmath` package can be changed in a class file when different conventions are in use.

11-5-1

A series H_1, H_2, \dots, H_n , a sum $H_1 + H_2 + \dots + H_n$, an orthogonal product $H_1 \times H_2 \times \dots \times H_n$.

```
\usepackage{amsmath}
```

A series H_1, H_2, \dots, H_n , a sum $H_1 + H_2 + \dots + H_n$, an orthogonal product $H_1 \times H_2 \times \dots \times H_n$.

If the dots fall at the end of a mathematical formula, the next object will be something like `\end` or `\]` or `$`, which does not give any information about how to place the dots. In such a case, you must help by using `\dotsc` for “dots with commas”, `\dotsb` for “dots with Binary operator/Relation symbols”, `\dotsm` for “multiplication dots”, `\dotsi` for “dots with integrals”, or even `\dotso` for “none of the above”. These commands should be used only in such special positions: otherwise you should just use `\dots`.

In this example, low dots are produced in the first instance and centered dots in the other cases, with the space around the dots being nicely adjusted.

11-5-2

A series H_1, H_2, \dots , a sum $H_1 + H_2 + \dots$, an orthogonal product $H_1 \times H_2 \times \dots$, and an infinite integral:

```
\usepackage{amsmath}
```

A series H_1, H_2, \dots , a sum $H_1 + H_2 + \dots$, an orthogonal product $H_1 \times H_2 \times \dots$, and an infinite integral: $\int_{H_1} \int_{H_2} \dots -\Gamma d\Theta$

$$\int_{H_1} \int_{H_2} \dots -\Gamma d\Theta$$

You can customize the symbols and spacing produced by the `\dots` command in various contexts by redefining the commands `\dotsc`, `\dotsb`, `\dotsm`, and `\dotsi`; this would normally be done in a class file. Thus, for example, you could decide to use only two dots in some cases.

For vertical ellipsis, standard \LaTeX already offers `\vdots`, but while this works well in situations such as inside matrices (with centered cells), it is rather suboptimal when indicating continuation in math displays. Here it is usually preferable if the vertical dots take the width of an equal sign or some other symbol so that they appear centered with respect to nearby relation symbols next to the alignment point.

*mathtools additions
to amsmath*

This is provided by `mathtools` with the command `\vdotswithin`. It takes one argument (typically a relational *symbol* such as `=`), measures the width of the formula $\{symbol\}$, and then typesets the vertical dots centered in a box of that width.

11-5-3

$a = b + c$ $a = b + c$

```
\usepackage{mathtools}
```

\vdots \vdots

```
\begin{align*} a &= b+c & \& a &= b+c & \\\
```

$x = y + z$ $x = y + z$

```
 & \vdots & \& \vdotswithin{=} \\\
```

```
 x &= y+z & \& x &= y+z & \end{align*}
```

If vertical ellipsis are used in formulas, then there is often too much white space above and below, because of the usual line separation in display formulas. To allow for shortening that space in this and other scenarios, `mathtools` offers the two commands

`\MTFlushSpaceAbove` (to be used directly after `\`) and `\MTFlushSpaceBelow` (to end the line *instead* of `\`). If we apply them, we get:

$a = b + c$	$a = b + c$	<code>\usepackage{mathtools}</code>	
\vdots	\vdots	<code>\begin{align*} a &= b+c & & a &= b+c & & \\\ \MTFlushSpaceAbove</code>	
$x = y + z$	$x = y + z$	<code>& \vdotswithin{=} & & \vdotswithin{=} & \MTFlushSpaceBelow</code>	
		<code>x &= y+z & & x &= y+z & \end{align*}</code>	

11-5-4

For the most common case of vertical dots after an alignment point there is also `\shortvdotswithin{<symbol>}`, which is a shorthand for

`\MTFlushSpaceAbove & \vdotswithin{<symbol>} \MTFlushSpaceBelow`

and therefore has to follow a `\`, and there cannot be anything else in that row — which is why we could not use it in the previous example. If you ever need it, there is also `\shortvdotswithin*`, which differs in that it typesets the `\vdotswithin` before and not after the alignment point.

The `mathdots`
package extensions

Standard \LaTeX already offers `\ddots` for diagonal dots, but if you need them, in the other direction you can load the `mathdots` package by Dan Luecking, which offers `\iddots` for this purpose. Note, though, that this package also changes the definitions of `\ddots`, `\vdots`, and if `amsmath` is loaded, the two accents `\ddot` and `\ddddot` so that they are slightly better placed when used at different sizes, e.g., in exponents. Especially for the accents the latter feature can be quite interesting. Here is an example:

				<code>\usepackage{array,amsmath,mathdots}</code>	
command	large	script	tiny	<code>\begin{tabular}{l@{>{\large\$}c<{\\$}>{\scriptsize\$}c<{\\$}>{\tiny\$}c<{\\$}}</code>	
				<code>>{\tiny\$}c<{\\$}}</code>	
<code>\ddots</code>	\ddots	\ddots	\ddots	command & <code>\multicolumn{1}{c}{large}</code>	
				& <code>\multicolumn{1}{c}{script}</code>	
<code>\iddots</code>	\iddots	\iddots	\iddots	& <code>\multicolumn{1}{c}{tiny}</code>	<code>\\[3pt]</code>
				<code>\verb=\ddots=</code>	<code>& \ddots & \ddots & \ddots & \\</code>
<code>\vdots</code>	\vdots	\vdots	\vdots	<code>\verb=\iddots=</code>	<code>& \iddots & \iddots & \iddots & \\</code>
<code>\ddot{Z}</code>	\ddot{Z}	\ddot{Z}	\ddot{Z}	<code>\verb=\vdots=</code>	<code>& \vdots & \vdots & \vdots & \\</code>
<code>\ddddot{Z}</code>	\ddddot{Z}	\ddddot{Z}	\ddddot{Z}	<code>\verb=\ddot{Z}=</code>	<code>& \ddot{Z} & \ddot{Z} & \ddot{Z} & \\</code>
				<code>\verb=\ddddot{Z}=</code>	<code>& \ddddot{Z} & \ddddot{Z} & \ddddot{Z} & \\</code>
				<code>\end{tabular}</code>	

11-5-5

11.5.2 Horizontal extensions in standard \LaTeX

In principle, any mathematical accent command can be set up to produce the appropriate glyph from a range of widths whenever these are provided by the available fonts. However, in standard \LaTeX there are only two such commands: `\widehat` and `\widetilde`.

This section describes a few commands that produce constructions similar to these extensible accents. All, except `\overbrace` and `\underbrace`, produce compound symbols of mathematical class Ordinary (see Section 11.8.1 on page 209). They are illustrated in this example:

11-5-6

$$\widehat{\psi_{\delta}(t)E_th} \neq \widetilde{\psi_{\Delta}(t)E_th}$$

$$\overline{\psi_{\delta}(t)E_th} \approx \underline{\psi_{\Delta}(t)E_th}$$

$$\overrightarrow{\psi_{\delta}(t)E_th} \cong \overleftarrow{\psi_{\Delta}(t)E_th}$$

Combinations are possible too:

$$\overline{\overrightarrow{\psi_{\delta}(t)E_th}} \leq \underline{\overleftarrow{\psi_{\Delta}(t)E_th}}$$

Braces have extra possibilities as explained below.

$$\overbrace{\psi_{\delta}(t)E_th} \doteq \underbrace{\psi_{\Delta}(t)E_th}$$

```
\[ \widehat{\psi_{\delta}(t) E_t h} \neq
\widetilde{\psi_{\Delta}(t) E_t h}
\]
\[ \overline{\psi_{\delta}(t) E_t h} \approx
\underline{\psi_{\Delta}(t) E_t h}
\]
\[ \overrightarrow{\psi_{\delta}(t) E_t h} \cong
\overleftarrow{\psi_{\Delta}(t) E_t h}
\]
Combinations are possible too:
\[ \overline{\overrightarrow{\psi_{\delta}(t) E_t h}}
\leq
\underline{\overleftarrow{\psi_{\Delta}(t) E_t h}}
\]
Braces have extra possibilities as explained below.
\[ \overbrace{\psi_{\delta}(t) E_t h} \doteq
\underbrace{\psi_{\Delta}(t) E_t h}
\]
```

The `\overbrace` and `\underbrace` commands are somewhat special in that they produce compound symbols of the Operator class and take `\limits`. This means that you can easily attach some explanatory text or other material to the brace. For this the `\text` command from `amsmath` can be very useful.

11-5-7

$$\overbrace{\psi_{\delta}(t)E_th}^{\text{explanation}} = \underbrace{\psi_{\Delta}(t)E_th}_{\iff x>0}$$

```
\usepackage{amsmath} % for the \text command
\[
\overbrace{\psi_{\delta}(t) E_t h}^{\text{explanation}} =
\underbrace{\psi_{\Delta}(t) E_t h}_{\iff x > 0}
\]
```

Another horizontally extensible feature of \LaTeX is the bar in a radical sign; it is described at the end of the next subsection.

11.5.3 Further horizontal extensions

To the basic set of horizontally extensible structures, `amsmath` adds a few more arrows and perhaps more importantly also reimplements `\overrightarrow` and `\overleftarrow` so that they change their mathematical style. This means that they look right when used, for example, in fractions or subscripts/superscripts (see Section 11.7.1 on page 195). In contrast, the arrowheads in standard \LaTeX always stay

at the same size so that the commands without `amsmath` are suitable for use only at the top level of displayed mathematics.

$$\overrightarrow{\psi_\delta(t)E_th} \approx \overleftarrow{\psi_\Delta(t)E_th} \quad \text{No style change without amsmath}$$

$$\overrightarrow{\psi_\delta(t)E_th} \simeq \overleftarrow{\psi_\Delta(t)E_th} \quad \text{Needs amsmath}$$

$$\overleftrightarrow{\psi_\delta(t)E_th} \sim \overleftrightarrow{\psi_\Delta(t)E_th} \quad \text{Needs amsmath}$$

```
\usepackage{amsmath}
\begin{align*}
\overrightarrow{\psi_\delta(t)E_th}
&\approx \overleftarrow{\psi_\Delta(t)E_th} \\
&\& \text{No style change} \\
&\& \text{without \textsf{amsmath}} \\
\underrightarrow{\psi_\delta(t)E_th}
&\simeq \underleftarrow{\psi_\Delta(t)E_th} \\
&\& \text{Needs \textsf{amsmath}} \\
\overleftrightharpoonup{\psi_\delta(t)E_th}
&\sim \underleftrightharpoonup{\psi_\Delta(t)E_th} \\
&\& \text{Needs \textsf{amsmath}}
\end{align*}
```

11-5-8

mathtools *additions*
to **amsmath**

The **mathtools** package offers two additional commands for producing over and under brackets.

```
\overbracket [bracket thickness] [bracket height] {content}
\underbracket [bracket thickness] [bracket height] {content}
```

Both commands have one mandatory *content* argument for the material bracketed and two optional arguments to specify the *bracket thickness* and *bracket height*. The defaults are chosen to blend well with the size and thickness of `\underbrace`, but if you do not like them or need several different weights, use the optional arguments.

The next example shows a couple of variations. Note the use of `\`, and `!` to make the brace and the innermost bracket slightly wider on the right without changing the spacing of the `+` signs.

$$\overbracket{a + b + \overbrace{c + d} + e + f}$$

$$\underbracket{a + b + \underbrace{c + d} + e + f}$$

```
\usepackage{mathtools}
\begin{gather*}
\overbracket{a + \underbracket{b + \overbrace{c + d},}! + e + f} \\
\overbracket[1.5pt][3pt]{a +}
\underbracket[3pt][4pt]{b +}
\overbracket[.7pt][2pt]{c + d},! + e + f}
\end{gather*}
```

11-5-9

The **mathtools** package also corrects some spacing problems with `\underbrace` and `\overbrace` because the \LaTeX versions are optimized for 10pt body font size and do not work that well with other sizes. With some math font families, such as Concrete Math, the original definitions are superior, though (because of a different brace design), and if that is the case, specify

```
\let\underbrace\LaTeXunderbrace \let\overbrace\LaTeXoverbrace
```

in the preamble of your document to get the \LaTeX definitions back.

<i>pattern</i>	<i>Effect</i>	<i>pattern</i>	<i>Effect</i>
l	⌞	A	Horizontal line (anchor) with the width of a D or U
L	⌞	O	Single empty fill (same width as 1)
r	⌞	1, ..., 9	Copies of regular fill —
R	⌞	@{ <i>material</i> }	Places <i>material</i> into brace
U	⌞	!{ <i>length</i> }	Regular fill of specific <i>length</i>
D	⌞	*{ <i>num</i> }{ <i>material</i> }	Repeat <i>material</i> a total of <i>num</i> times
,	⌞ Bracket end up	, [<i>height</i>]	Bracket up with extra <i>height</i>
,	⌞ Bracket end down	, [<i>height</i>]	Bracket down with extra <i>height</i>

Table 11.4: Pattern elements to construct braces and brackets

11.5.4 abraces — Customizable over and under braces

If you have a need for more specialized over or under braces, e.g., with special tips, or the middle part of the brace not centered or dashes instead of straight horizontal parts, etc., then take a look at the `abraces` package by Werner Grundlingh.

This package offers a construction method (somewhat modeled after the preamble of a `tabular`) allowing for a huge number of variant extensible braces.

`\aoverbrace[pattern]{material}` `\aunderbrace[pattern]{material}`

Without the optional argument the commands behave just like `\overbrace` and `\underbrace`, and if you load the package with the option `overload`, the standard \TeX commands get the optional argument added so that you can continue to use the standard names.

The optional argument lets you construct specially formed braces by specifying a *pattern* out of the characters given in Table 11.4. For example, the standard over brace would have the specification of `L1U1R` where the two numbers represent the horizontal filler parts and their values define the ratio, i.e., “1:1” in that case. Thus, if you want to move the middle part to the left, you could use a ratio like “1:3” or “2:5”, etc. Similarly, if you want to have several “middle” parts, place several U or D characters at the right point into the pattern. A few variants are shown in the following example:

11-5-10

$$\begin{array}{c}
 \overbrace{a^3 + 3ab^2 + 3a^2b + b^3} \\
 \text{Some text with a brace} \\
 \underbrace{x_1, x_2, x_3, \dots, x_n} \\
 \underbrace{(a+b)^2} = \underbrace{a^2 + 2ab + b^2}
 \end{array}$$

```

\usepackage{abraces,amsmath}
\begin{gather*}
  \aoverbrace[L1U3R]{a^3 + 3ab^2 + 3a^2b + b^3} \\
  \aunderbrace[l1U1D1U1r]{\text{Some text with a brace}} \\
  \aunderbrace[l10@{\ldots}04r]{x_1, x_2, x_3, \dots, x_n} \\
  \aunderbrace['1']{\smash[b]{(a+b)}}\nolimits^2 \\
  = \aunderbrace['1, [5pt]1']{\smash[b]{\{; a^2 + 2ab + b^2\}}}
\end{gather*}

```

Visual adjustments
and other
fine-tuning

The last line of the previous example is interesting on three accounts. For one, `\aunderbrace` takes limits to add material above or below the brace as discussed later, but here the `^2` is meant to apply to $(a+b)$, so we need `\nolimits` to cancel this.¹ The second adjustment concerns the vertical position of the brackets. Given that the first one contains material with a parenthesis adding to the depth, the bracket would be placed lower than the second one. To correct this we use `\smash` to ignore the depth on both sides. This brings the bracket fairly close to the formula parts; an alternative there would have been to add a `\mathstrut`. Finally, we also add some extra space at the beginning of the formula part embraced by the second bracket to make it appear visually balanced. See Section 11.7 on page 194 for more examples of such fine-tuning.

Nesting the commands is equally possible as long as you do not need braces that overlap. In the latter case take look at the `underoverlap` package discussed in the next section. Both packages can be jointly used as shown in Example 11-5-18 on page 190.

$$x + \overbrace{y + z}^{} - a$$

```
\usepackage{abrcases,amsmath}
\[ \aoverbrace[L1U6R]{x +
  \aunderbrace[l6D1r]{ \aoverbrace[,1,]{y+z} - a} } \]
```

11-5-11

If you need a certain pattern repeatedly, you can save yourself some effort by defining an additional pattern character and assigning the pattern to it.

```
\newbracespec{char}{pattern-elements}
```

This declaration is comparable to the `\newcolumntype` approach in the `array` package. Once given, the *char* can be used in any *pattern* representing the *pattern-elements*. Even though the declaration has “new” in its name, it is perfectly permissible to use it to overwrite a previously defined *char*, even one of the predefined ones — though that means its original functionality is lost and so seldom a good idea.

The approach is used in the next example, in which we define the pattern element `s` representing a brace with two tips and a few dots. Half of the brace is colored blue to show that coloring is possible too.

$$\underbrace{x_1, x_2, x_3, x_4, \dots, x_n}_{}$$

```
\usepackage{abrcases,amsmath,color}
\newbracespec{s}{l1D2@{\, \ldots}0@{\color{blue}\ldots\,}2D1r}
\[ \aunderbrace[s]{x_1, x_2, x_3, x_4, \ldots, x_n} \]
```

11-5-12

As you can observe in the previous example, any color change (or in fact any other declaration) inside an `@{...}` pattern element is applied to the remaining part of the pattern (or until changed again). Thus, if you want only to color the dots in the example, another `\color{black}` or the use of `\textcolor` is needed.

Attaching super and
subscripts

In many cases one does not only want to brace some part of a formula but also add some text or a formula above or below the brace. This can be easily achieved with

¹Without it the `^2` would not be displayed at all, because the specified *pattern* does not contain any D elements to attach it to.

the help of `^` and `_` after the mandatory argument. Normally you would use `^` with `\aoverbrace` and `_` with `\aunderbrace`, but it is possible to apply either or both.

The material is placed centered around the tip(s) of the brace. For this the *pattern* is evaluated in the following way: material in `^{\dots}` is placed above the first U or A pattern element, while material in `_{\dots}` attaches below the first D or A element. If you have several Us or Ds, you can attach material to each of them by using `&` to split the material in several parts that are then applied from left to right.

In the next example we set up a brace pattern with three anchor points for `^{\dots}` (U, A, and another U). As shown in the example, you can attach superscript material to any of them using the right number of `&` symbols. For a subscript there is only one anchor point, because the pattern has no D so that the subscript made with `_{\dots}` can attach only to the A element in the center.

If you split the super or subscript into more parts than you have anchors available, you will get an error message, and the excess parts are dropped. This is what happens in the last line of the next example where the word “dropped” is not in the output.

*Special cases
involving &*

If you need `&` as an ordinary character, just use `\&` as usual. However, if your super or subscript material does contain an array, `smallmatrix`, or some other environment that uses `&` in its syntax, you need to hide this use from a braces by surrounding it with an extra brace group as shown below:

11-5-13

$$\begin{array}{c} \overbrace{\text{a braced formula}}^{x \& y} \\ \overbrace{\text{a braced formula}}^{x \quad y} \\ \overbrace{\text{a braced formula}}^{x \qquad z} \\ \overbrace{\text{a braced formula}}^{\qquad z} \\ \underbrace{\text{a braced formula}}_{\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}} \end{array}$$

```
\usepackage{abraces,amsmath}
\newbracespec{s}{L1U1A1U1R}

\begin{gather*}
  \aoverbrace[s]{\text{a braced formula}}^{x \& y} \\
  \aoverbrace[s]{\text{a braced formula}}^{x \& y} \\
  \aoverbrace[s]{\text{a braced formula}}^{x \& \& z} \\
  \aoverbrace[s]{\text{a braced formula}}^{\& \& z} \\
  _{\begin{smallmatrix} a&b \\ c&d \end{smallmatrix}} \& \text{dropped}
\end{gather*}
```

Up to now all examples use a single *pattern* for constructing the brace as well as placing any super or subscripts. In nearly all circumstances this is all you need to get the results you are after. There are, however, a few cases where you want the annotation placed in a way that is incompatible with the brace construction; e.g., you want a normal brace above and also a centered annotation below the formula.

The extended syntax

For these cases, both `\aoverbrace` and `\aunderbrace` offer a second optional argument so the extended syntax (with *above* and *below* also both optional) is actually as follows:

```
\aoverbrace [brace-pattern] {material} [anchor-pattern] ^{above} _{below}
\aunderbrace [brace-pattern] {material} [anchor-pattern] ^{above} _{below}
```

If the optional *anchor-pattern* argument is given, it is used instead of the *brace-pattern* for determining the position of any super or subscript annotations. The fact that there is only a single pattern is not a problem, even if both `^{\dots}` and `_{\dots}` are

used, because you can guide the anchoring either by supplying the right number of & characters or by specifying a suitable combination of U (only for superscripts), D (only for subscripts), and A (anchor for both) in the *anchor-pattern*. In the example below we use 1A1 in the *anchor-pattern* to have one centered anchor for both super and subscripts:

with text above
 $\overbrace{\text{a braced formula}}$
 and some below

```
\usepackage{abraces,amsmath}
\[
  \aoverbrace{\text{a braced formula}}[1A1]
    ^{\text{with text above}}
    _{\text{and some below}}
\]
```

11-5-14

The problem of
 trailing optional
 arguments

There is a potential problem with a syntax using trailing optional arguments: if no optional argument is wanted but the command is followed by a bracket group (even on the next line), then that group is parsed as an optional argument and not considered part of the formula. Fortunately, with the `abraces` commands it is easy to identify that this is a mistake: if there is neither a super nor a subscript, then such a bracket group is not an *anchor-pattern* argument (as that would be of no use) but must belong to the formula itself. The first line in the example shows such a case and the fact that it is correctly handled.

However, if what follows is an open bracket that does not have a matching closing bracket, then this no longer works because the parser scans for the closing symbol until it finds one (unlikely), or until it finds a `\par`, and then responds with a low-level error message. The solution for this scenario is therefore to explicitly tell \LaTeX to stop scanning earlier, for example, by adding `\relax`.

$\overbrace{(x+y+z)}[a,b]$
 $\underbrace{(x+y+z)}[a,b]$

```
\usepackage{abraces,amsmath}
\begin{gather*}
  \aoverbrace{[ , 1 , ]{(x+y+z)}} [a,b] \quad \backslash\backslash
  \aunderbrace{[' 1 ']{(x+y+z)}} \relax [a,b]
\end{gather*}
```

11-5-15

Over or under
 braces split across
 several display lines

With all these tools at hand it is fairly simple to produce braces that are split across two lines in a display. To make it even simpler we define five new pattern characters: B or b (for begin brace), e or E (for end brace), and M (for any middle part with a tip). The uppercase letters produce a brace containing a middle part with a tip, while the lowercase ones do not. Thus, you would normally select one upper and one lowercase character (depending on where you want to place your annotations, if any). Also note the use of `\enspace` to run the brace a little wider at the open side to indicate that it is continuing.

In the example the M element is only indirectly used when defining B and E, but if you want to span three or more lines, you can use it for the middle one. If you need a continuation without any tip, then just use the pattern 1 on its own instead.

```

\usepackage{amsmath} \usepackage[overload]{abraces}
\newbracespec{M}{1U1} \newbracespec{B}{LM} \newbracespec{e}{1R}
\newbracespec{b}{L1} \newbracespec{E}{MR}

\begin{multiline*}
  f(x)=a_0+a_1x+a_2x^2+
  \overbrace[B]{a_3x^3 + a_4x^4 + \dots + a_{i-1}x^{i-1} + \enspace}
    ~{\text{some explanation}} \\\
  \overbrace[e]{\enspace a_ix^i + a_{i+1}x^{i+1}} + \dots + a_{n-1}x^{n-1}
\end{multiline*}

```

11-5-16

$$f(x) = a_0 + a_1x + a_2x^2 + \overbrace{a_3x^3 + a_4x^4 + \cdots + a_{i-1}x^{i-1}}^{\text{some explanation}} + \underbrace{a_ix^i + a_{i+1}x^{i+1} + \cdots + a_{n-1}x^{n-1}}_{\text{some explanation}}$$

11.5.5 underoverlap — Partly overlapping horizontal braces

While it is possible to nest `\overbrace` or `\underbrace` commands (or the equivalents from the `abraces` package), it is rather difficult with the standard tools to produce partly overlapping braces within a single formula. If this is needed, you can use the `underoverlap` package by Michiel Helvensteijn.¹ It offers by default four commands that can produce partly overlapping structures. Others can be added as needed.

$\text{\UOLoverbrace}\{private\}[common]$	$\text{\UOLunderbrace}\{private\}[common]$
---	--

The brace spans both the *private* and the *common* parts, i.e., as if both parts are inside the argument of `\overbrace`. However, the optional *common part* is typeset only by the next `\UOL . .` command, which therefore should follow immediately. If not, you get results as shown in the second and third formula of the next example.

By default `\UOLoverline` and `\UOLunderline` are also available, and all commands can be intermixed freely.

11-5-17

$$a + \overbrace{b + c + d}^{\text{both}} + f + g \quad (1)$$

$$a + \overbrace{b + + f + q}^{\text{fine}} \quad (2)$$

$$a + \overbrace{b + + fc + d + g}^{\text{clearly wrong}} \quad (3)$$

```
\usepackage{underoverlap,amsmath}
\begin{gather} a + \UOLoverbrace{b +}[c + d]^{\text{both}} \\
\qquad \qquad \qquad \UOLunderline{+ f}_{\text{fine}} + g \quad \backslash \\
a + \UOLoverline{b +}[c + d]^{\text{wrong!!}} + f + g \quad \backslash \\
a + \UOLoverbrace{b +}[c + d]^{\text{clearly wrong}} \\
\qquad + f \UOLunderlinebrace{+ g}_{\text{too!}} \quad \end{gather}
```

¹An alternative based on an `array`-like syntax is the `oubrace` package by Donald Arseneau.

\llbracket	\lbracket or <code>\lbrack \rbrack</code>	$\{ \}$	<code>\{ \}</code> or <code>\lbrace \rbrace</code>	$()$	$()$
$\langle \rangle$	<code>\langle \rangle</code>	$\lceil \rceil$	<code>\lceil \rceil</code>	$\lfloor \rfloor$	<code>\lfloor \rfloor</code>
$()$	<code>\lgroup \rgroup</code>	\int	<code>\lmoustache \rmoustache</code>	$\llcorner \lrcorner$	<code>\lvert \rvert</code>
\lll	<code>\lVert \rVert</code>	$\llbracket \rrbracket$	<code>\llbracket \rrbracket</code> ^(STM)		
$ $	<code> </code> or <code>\vert</code>	\uparrow	<code>\arrowup</code>	\updownarrow	<code>\bracketup</code>
\backslash	<code>\backslash</code>	$/$	<code>/</code>	\lvert	<code>\lvert</code> or <code>\Vert</code>
\Uparrow	<code>\Uparrow</code>	\downarrow	<code>\downarrow</code>	\uparrow	<code>\uparrow</code>
\Updownarrow	<code>\Updownarrow</code>	\Downarrow	<code>\Downarrow</code>	\Uparrow	<code>\Uparrow</code>
\Updownarrow	<code>\Updownarrow</code>	\cdot	<code>\cdot</code>	$\sqrt{}$	<code>\sqrt{}</code>

Symbols in *blue* require either the `amsmath` package or, if additionally denoted with ^(STM), the `stmaryd` package. A period (`.`) is not itself an extensible symbol, but it can be used to produce an “invisible” delimiter. The `\sqrt{}` symbol cannot be used with `\left`, `\right`, or `\middle`.

Table 11.5: Vertically extensible symbols

With the declaration `\newUOLdecorator` you can even define new `\UOL . . .`-like commands, and there is also the possibility of augmenting existing commands (like `\overline`) so that they behave as `\UOL . . .` commands.

The next example is not going to win us a design award, but it shows both features and also the fact that with a little care you can chain these commands. Note, however, that there are a number of restrictions that need to be taken into account. So if you intend to define your own variants, consult the package documentation.

```

\usepackage{underoverlap,abraces}
\newUOLdecorator\rightunderbrace{\aunderbrace[14D1r]{#1}}
\UOLaugment\underline
\UOLaugment\overleftarrow \UOLaugment\overrightarrow
\l[ \underline{a +}[b] \overrightarrow{+}[c + d]
      \rightunderbrace{+ e +}[f] \overleftarrow{+ g}
\l

```

11-5-18

11.5.6 Vertical extensions

While only a few symbols are horizontally extensible, there is a much larger range available with vertical extensions. The full list is given in Table 11.5. These symbols become extensible only in certain usages; they must all be based on a construction of the following form:

$$\backslash\mathrm{left}\langle\mathrm{ext-Open}\rangle \quad \dots \quad \backslash\mathrm{middle}\langle\mathrm{ext-Middle}\rangle \quad \dots \quad \backslash\mathrm{right}\langle\mathrm{ext-Close}\rangle$$

The `\middle<ext-Middle>` is optional, while `\left` and `\right` have to be present. The `<ext-Open>`, `<ext-Middle>`, and `<ext-Close>` can be any of the symbols (except `\sqrt`) listed in Table 11.5, or possibly others if additional packages are loaded. They must be symbols that have been set up to be extensible using the methods described in [113], which is part of every $\mathrm{\LaTeX}$ distribution; thus, a symbol must be available to represent the absence of an actual glyph. This symbol, which is sometimes called the *null delimiter*, is denoted by a period “.”.

The sizes of the actual glyphs used to typeset the extensible symbols are chosen to fit with the vertical size (height and depth) of the typeset *subformula* that lies in between them; the exact details of how this is done, and of the parameters that affect the process, can be found in Chapter 17 and Appendix G (Rule 19) of *The $\mathrm{\TeX}$ book* [84]. One can also request specific sizes for such symbols as explained in Section 11.7.4 on page 199.

The $\mathrm{\TeX}$ engine’s way of scaling delimiters with the help of `\left` and `\right` has a problem: it may in some cases change the spacing with respect to the material before and after. This can be avoided by using `\mleft` and `\mright` from the `mleftright` package instead; see the discussion in Section 11.8.1 on page 211 for details.

The radical sign `\sqrt` is even more amazing than the delimiters — it grows both vertically and horizontally to fit the size of its argument. In $\mathrm{\LaTeX}$ it is typically not used directly but accessed via the `\sqrt` command, which is discussed further in Section 11.7.5 on page 199.

 Possible spacing issues with `\left` and `\right`

11-5-19

$$\sqrt{1 + \sqrt{2 + \sqrt{3 + \sqrt{4 + \sqrt{5 + \sqrt{6 + \sqrt{7 + \sqrt{8 + x}}}}}}}}$$

```
\[
\sqrt{1 + \sqrt{2 +
\sqrt{3 + \sqrt{4 +
\sqrt{5 + \sqrt{6 +
\sqrt{7 + \sqrt{8 + x}}}}}}}
\]
```

11.6 Words in mathematics

Most of the time formulas consist only of symbols and individual letters denoting variables. However, sometimes ordinary text is made part of a formula, either to annotate some part of it or to continue the outer text with words like “and”, etc. In addition, a number of common operators are typeset using words rather than symbols.

11.6.1 The `\text` command

Math font-changing commands such as `\mathrm` are not intended for putting normal text inside mathematics as the fonts used are fixed and may not bear any relation to the font used in the text surrounding the formula. To produce “text” fonts inside a formula in standard \LaTeX you can use `\textrm`, `\textsf`, etc., or you can simply use `\mbox` if you want to typeset in the font used outside the current mathematical material. However, one problem with all these commands in standard \LaTeX is that they always typeset their text in a fixed font size, regardless of the position in the formula.

The `amsmath` package improves¹ on this by additionally providing the command `\text`, which is similar to `\mbox` but is much better, ensuring that the text is set using the correct font size. It also modifies `\textrm` and friends to change the font size as necessary, as can be observed in the next example:

Some text outside the formula ...

Also, if $\Delta_{\text{max up}} \geq \Delta_{\text{min down}} + \epsilon$
(for all ups and downs) then
 $\Delta_{\text{sum of ups}} > \Delta_{\text{sum of downs}}$

```
\usepackage{amsmath}
Some text outside the formula \ldots
\begin{multline*}
\text{Also, if } \Delta_{\text{max up}}
\geq \Delta_{\text{min down}} + \epsilon \\
\text{(for all ups and downs) then} \\
\Delta_{\text{sum of ups}} > \Delta_{\text{sum of downs}}
\end{multline*}
```

11-6-1

11.6.2 Operator and function names

The names of many well-known mathematical functions (such as `log` and `sin`) and operators (such as `max` and `lim`) are traditionally typeset as words (or abbreviations) in roman type so as to visually distinguish them from shorter variable names that are set in “math italic”. The most common function names have predefined commands to produce the correct typographical treatment; see Table 11.6 on the next page. Most functions are available in standard \LaTeX ; those listed in blue in the table require loading `amsmath`. The functions marked with (ℓ) may “take limits” in display formulas (see Section 11.4.4).

$$\lim_{x \rightarrow 0} \frac{\sin^2(x)}{x^2} = 1$$

$$\lim_{n \rightarrow \infty} |a_{n+1}|/|a_n| = 0$$

$$\lim_{\rightarrow} (m_i^\lambda \cdot M)^* \leq \lim_{A/p \rightarrow \lambda(A)} A_p \leq 0$$

```
\usepackage{amsmath} \newcommand{\abs[1]{\lvert#1\rvert}
\begin{gather*}
\lim_{x \rightarrow 0} \frac{\sin^2(x)}{x^2} = 1 \\
\varliminf_{n \rightarrow \infty} |a_{n+1}| / |a_n| = 0 \\
\varinjlim (m_i^\lambda \cdot M)^* \leq \lim_{A/p \rightarrow \lambda(A)} A_p \leq 0
\end{gather*}
```

11-6-2

¹This particular improvement is also available separately in the package `amstext`.

arccos	<code>\arccos</code>	arcsin	<code>\arcsin</code>	arctan	<code>\arctan</code>
arg	<code>\arg</code>	cos	<code>\cos</code>	cosh	<code>\cosh</code>
cot	<code>\cot</code>	coth	<code>\coth</code>	csc	<code>\csc</code>

Blue functions require the amsmath package. (ℓ) indicates that the operator takes limits in displays.

Table 11.6: Predefined operators and functions

New functions of this type are needed frequently in mathematics, so the amsmath package provides a general mechanism for defining new “operator names”.¹

`\DeclareMathOperator*{cmd}{text} \operatorname*{text}`

`\DeclareMathOperator` defines *cmd* to produce *text* in the appropriate font for “textual operators”. If the new function being named is an operator that should, when used in displays, “take limits” (so that any subscripts and superscripts are placed in the “limits” positions, above and below, as with, for example, \lim , \sup , or \min), then use the starred form `\DeclareMathOperator*`. In addition to using the proper font, `\DeclareMathOperator` sets up good spacing on either side of the function name when necessary. For example, it gives $A \text{ meas } B$ instead of $A \text{ meas} B$. The *text* argument is processed using a “pseudo-text mode” in which

 *Operator text is somewhat special*

- The hyphen character `-` prints as a text hyphen (and not as a minus sign); see `\supminus` in the next example.
- The asterisk character `*` prints as a raised text asterisk (not centered).
- Otherwise, the text is processed in math mode so that spaces are ignored and you can use subscripts, superscripts, and other elements.

The related command `\operatorname` (and its `*`-form) simply turns its argument into a function name, as in Example 11-2-11 on page 137. It is useful for “one-off” operators.

¹This functionality is also separately available in the package `amsopn`.

The next example shows how to provide the command `\meas` for the new function name “meas” (short for measure) and the operator functions `\esssup` and `\supminus`, both of which take limits.

$$\|f\|_\infty = \operatorname{ess\,sup}_{x \in R^n} |f(x)|$$

$$\operatorname{meas}_1 \{u \in R_+^1 : f^*(u) > \alpha\} = \operatorname{ess\,sup}_{x \in R^i} \operatorname{meas}_i \{u \in R^n : |f(u)| \geq \alpha\} \\ (\forall \alpha \in \operatorname{sup-minus}_{f^*} R_{*+})$$

```
\usepackage{amsmath}
\DeclareMathOperator \meas {meas}
\DeclareMathOperator*\esssup {ess \, sup}
\DeclareMathOperator*\supminus{sup - minus*}
\newcommand\abs [1]{\lvert#1\rvert}
\newcommand\norm[1]{\lVert#1\rVert}
\begin{multline*}
\norm{f}_{\infty} = \esssup_{x \in R^n} \abs{f(x)} \\\
\meas_1 \{ u \in R_+^1 \colon f^*(u) > \alpha \} = \\\
\esssup_{x \in R^i} \{ u \in R^n \colon \abs{f(u)} \geq \alpha \} \\\
(\forall \alpha \in \supminus_{f^*} R_{*+})
\end{multline*}
```

11-6-3

Unfortunately, such declarations must appear in the preamble, so it is not possible to change a declaration temporarily. In fact, `\DeclareMathOperator` works only for command names that have not been used previously, so it is not possible to overwrite an existing command directly. To do so, you must first remove the previous definition (in this case, of `\csc`) before redeclaring it; this removal is accomplished by using low-level \TeX coding, as \LaTeX provides no method for completing this task.

$$\overline{\lim}_{n \rightarrow \infty} \mathcal{Q}(u_n, u_n - u^\#) \geq \operatorname{cosec}(\mathcal{Q}'(u^\#)) \quad (1)$$

```
\usepackage{amsmath}
%% Low-level TeX needed here to cancel
%% the old definition of \csc:
\let \csc \relax
\DeclareMathOperator\csc{cosec}
\newcommand\calQ{\mathcal{Q}}
\begin{equation}
\varlimsup_{n \rightarrow \infty}
\calQ(u_n, u_n - u^{\#})
\geq \csc(\calQ'(u^{\#}))
\end{equation}
```

11-6-4

11.7 Fine-tuning the mathematical layout

Although \LaTeX generally does a good job of laying out the elements of a formula, it is sometimes necessary to fine-tune the positioning. This section describes how to achieve some of the many detailed adjustments to the layout that are used to produce mathematical typography that is just a little bit better. Most of this section applies to all \LaTeX mathematical material, but a few features are available only with the `amsmath` or `mathtools` package; these are clearly labeled.

<i>Style</i>	<i>Superscript</i>	<i>Subscript</i>	<i>Numerator</i>	<i>Denominator</i>
D	S	S'	T	T'
D'	S'	S'	T'	T'
T	S	S'	S	S'
T'	S'	S'	S'	S'
S, SS	SS	SS'	SS	SS'
S', SS'	SS'	SS'	SS'	SS'

Table 11.7: Mathematical styles in subformulas

11.7.1 Controlling the automatic sizing and spacing

Letters and mathematical symbols normally get smaller, and are more tightly spaced, when they appear in fractions, superscripts, or subscripts. In total, \TeX has eight different styles in which it can lay out formulas:

D, D'	<code>\displaystyle</code>	Displayed on lines by themselves
T, T'	<code>\textstyle</code>	Embedded in text
S, S'	<code>\scriptstyle</code>	In superscripts or subscripts
SS, SS'	<code>\scriptscriptstyle</code>	In all higher-order superscripts or subscripts

The prime versions (D' , T' , etc.) represent the so-called *cramped* styles, which are similar to the normal styles except that superscripts are not raised so much.

\TeX uses only three type sizes for mathematics in these styles: text size (also used in `\displaystyle`), script size, and scriptscript size. The size of each part of a formula can be determined according to the following scheme:

<i>A symbol in style</i>	<i>is typeset in</i>	<i>and produces</i>
D, D', T, T'	text size	(text size)
S, S'	script size	(script size)
SS, SS'	scriptscript size	(scriptscript size)

In \TeX , the top-level part of a formula set in running text (within a $\$$ pair or between `\(. . . \)`) is typeset using text style (style T). A displayed formula (e.g., one between `\[. . . \]`) is typeset in display style (style D). The kind of style used in a subformula can then be determined from Table 11.7, where the last two columns describe the styles used in the numerator and the denominator of a fraction or similar construct, for example, produced with `\frac` or `\binom`. In particular, notice this difference between fractions in display and text style; in the latter case the numerator and denominator are typeset in script style, i.e., noticeably smaller.

The various styles can be seen in this example:

	<code>\normalsize</code>	%% Style:	
	<code>\[b</code>	%% D	
	<code>~0</code>	%% S	
	<code>+</code>	%% D	
	<code>\frac{(k + p)</code>	%% T	
	<code>_ {j'}</code>	%% S'	
	<code>% \displaystyle</code>	%% <-- possible modification	
	<code>\pm</code>	%% T	[D]
	<code>\frac{(f + q)</code>	%% S	[T]
	<code>~{(pk)</code>	%% SS	[S] v
	<code>~y</code>	%% SS	
	<code>_ {j'}}</code>	%% SS'	
	<code>{(h + y)}</code>	%% S'	[T']
	<code>{(1 + q)</code>	%% T'	
	<code>~{(pk)}</code>	%% S'	
	<code>\]</code>		

$$b^0 + \frac{(k+p)_{j'} \pm \frac{(f+q)^{(pk)_{j'}}}{(h+y)}}{(l+q)^{(pk)}}$$

11-7-1

You can change the layout of this example by explicitly specifying the style to be used in each part. For example, if you remove the comment character in front of `\displaystyle`, then some of the styles will change to those shown in brackets. The result looks like this:

$$b^0 + \frac{(k+p)_{j'} \pm \frac{(f+q)^{(pk)_{j'}}}{(h+y)}}{(l+q)^{(pk)}}$$

11-7-2

mathtools additions
to amsmath

In standard \LaTeX or `amsmath` it is not possible to explicitly request that a formula should be typeset in cramped style. The only possibilities you have is requesting one of the uncramped styles and letting \TeX decide the rest based on its logic described in Table 11.7 on the preceding page. However, with `mathtools` you have a command at your disposal that lets you ask for cramped style explicitly.

```
\cramped[mathstyle]{subformula}
```

The *subformula* is typeset in the cramped version of the current math style. In the optional *mathstyle* argument you can explicitly ask for a different cramped style by specifying `\displaystyle`, `\textstyle`, `\scriptstyle`, or `\scriptscriptstyle`. To the outer formula the *subformula* looks like a single object of type Ordinary. If that is not appropriate, you need to additionally use `\mathop`, etc., to change its interpretation (see Section 11.8 on page 208).

In the next example a sum is typeset in a display formula. In cramped style the superscripts are noticeably lowered, and in cramped `\textstyle` the sum operator

additionally takes no limits. See also page 204 for additional commands that provide subformulas in *cramped* style.

11-7-3

$$\sum_i x^{i^2} \neq \sum_i x^{i^2} \neq \sum_i x^{i^2}$$

```
\usepackage{mathtools}
\Large \[ \sum_i x^{i^2} \neq \cramped{\sum_i x^{i^2}}
\neq \cramped[\textstyle]{\sum_i x^{i^2}} \]
```

11.7.2 Subformulas

Whereas in text a pair of braces can simply indicate a group to which the effects of some declaration should be confined, within mathematics they do more than this. They delimit a subformula, which is always typeset as a separate entity that is added to the outer formula. As a side effect, subformulas are always typeset at their natural width and do not stretch or shrink horizontally when T_EX tries to fit a formula in a paragraph line during line breaking. As shown earlier, the subformula from a simple brace group is treated as if it was just a single symbol (of class Ordinary). An empty brace group, therefore, generates an invisible symbol that can affect the spacing. The exact details can be found in Chapters 17 and 18 and Appendix G of *The T_EXbook* [84].

 Subformulas are always typeset at their natural width

The contents of subscripts/superscripts and the arguments of many (but not all) commands, such as `\frac` and `\mathrel`, are also subformulas and get this same special treatment. Important examples of arguments that are not necessarily set as subformulas include those of `\bm` (see Section 12.2.1). If a group is needed only to limit the scope of a declaration (i.e., where a separately typeset subformula would be wrong), then `\begingroup` and `\endgroup` and not `{...}` should be used. Note that specialized mathematical declarations such as style changes apply until the end of the current subformula, irrespective of the presence of any other groups.

In the following artificial example you can see that the mathematical styles are restricted to the subformulas of the operator subscripts, but the `\scriptstyle` inside `\bm` is neither restricted to the argument nor does it end at the `\endgroup`. However, that group delimits the scope of the color declaration.

 Scope of mathematical styles

11-7-4

$$\sum_i \prod_j X_{i_j} = A + B + C$$

```
\usepackage{color,bm}
\[ \sum_{\textstyle i} \prod_{\scriptscriptstyle j} X_{i_j} = A
\begingroup\color{blue} + \bm{\scriptstyle B} + \endgroup C \]
```

11.7.3 Line breaking in inline formulas

L^AT_EX can break an inline formula (e.g., produced with `$...$`) over several lines if necessary, but it does this by default only after Relation or Binary symbols. The penalty for breaking at these positions is customizable through the T_EX counters `\relpenalty` (default value 500) and `\binoppenalty` (default 700). This means that L^AT_EX discourages breaking a formula, but if necessary, it slightly prefers breaking after a Relation over breaking after a Binary symbol. If you want to discourage this

further, you can set the parameter to even higher values, but it has to be done with low-level assignments, e.g.,

```
\binoppenalty = 10000 % never break after a Binary symbol
\relpenalty   = 0      % but do not penalize a break after a Relation
```

If you never want any automatic line breaking happening within a formula, you can set both to 10000 (T_EX's number for ∞), but you might have to also alter the definitions of `\pmod` and `\bmod` because they use their own hardwired penalties — or handle them manually.

The penalty values used are the ones that are current *at the end* of the formula; thus, changing their values anywhere inside a formula affects all Relation and Binary symbols, not just a single one. For local adjustments, it is therefore better to place explicit penalties inside a formula that you want to affect, i.e., `\nobreak` for preventing a break after a specific symbol¹ or `\allowbreak`, `\linebreak[num]`, or `\nolinebreak[num]` to allow, encourage, or discourage it at any point within the formula, which makes it possible to break anywhere.

In the next example L^AT_EX breaks after the `+` sign, which looks a bit odd with the *b* on its own at the beginning of the line. So we correct it by adding `\nobreak`, after which L^AT_EX uses the only remaining breakpoint after the `=` sign. This makes the line look a bit spaced out in the example (because it is so narrow), but in real life with a wider paragraph measure, this adjustment would be a clear improvement.

Some words of text before the formula $\sum x_i = a + b$ and after.	Some words of text before the formula \$ \sum x_i = a + b \$ and after.
Some words of text before the formula $\sum x_i = a + b$ and after.	Some words of text before the formula \$ \sum x_i = a + \backslash nobreak b \$ and after.

11-7-5

Do not use `\mbox`
or `\{...\}` to
prevent a line break
in a formula

You sometimes see the advice that putting some material into an `\mbox` is a good way to prevent an unwanted line break. While this is a good solution for preventing hyphenation in a word, it is not really good to keep several words together nor to keep a formula from breaking across lines. The reason is that the spaces in the formula (or between words) are then always set at their natural width and no longer participate in shrinking or stretching to fill the line. This also happens if you turn your formula into a subformula: they too are always set at their natural width.

The next example clearly shows the problem. Assume that you wanted to prevent the short formula from being broken, so you make sure, but after a few rewrites, it is no longer anywhere near a line break. In the first two paragraphs the formula is now set at its natural width, resulting in the word “af-ter” being broken, and only in the third paragraph was L^AT_EX able to squeeze the formula slightly to make everything fit onto a single line.

¹Normally T_EX evaluates all penalties in sequence, which makes it impossible to disallow a break through `\nobreak` if there is already a penalty allowing it. However, in formulas an explicit penalty after a Relation or Binary symbol overwrites the default penalty, so here it works.

However, even if the line breaking comes out reasonably well, a line with some spaces set at their natural width, while all others are squeezed or expanded, looks bad and distracts from reading — you should therefore avoid that trap.

11-7-6	Words before $\sum x_i = a + b$ and after.	Words before $\mbox{$ \sum x_i = a + b $}$ and after.
	Words before $\sum x_i = a + b$ and after.	Words before $\{ \sum x_i = a + b \}$ and after.
	Words before $\sum x_i = a + b$ and after.	Words before $\$ \sum x_i = \text{\nobreak a} + \text{\nobreak b} \$$ and after.

11.7.4 Big-g delimiters

To provide direct control of the sizes of extensible delimiters, \LaTeX offers four commands: `\big`, `\Big`, `\bigg`, and `\Bigg`. These take a single parameter, which *must* be an extensible delimiter, and they produce ever-larger versions of the delimiter, from 1.2 to 3 times as big as the base size.

Three extra variants exist for each of the four commands, giving four sizes of Opening symbol (e.g., `\bigl`), four sizes of Relation symbol (e.g., `\Bigm`), and four sizes of Closing symbol (e.g., `\Biggr`).¹ All 16 of these commands can (and must) be used with any symbol that can come after either `\left`, `\right`, or `\middle` (see Table 11.5 on page 190).

In standard \LaTeX the sizes of these delimiters are fixed. With the `amsmath` package, however, the sizes adapt to the size of the surrounding material, according to the type size and mathematical style in use, as shown in the next example. The same is true when you load the `exscale` package (see Section 9.5.7) or when you use a font package that implements the `exscale` functionality as an option (e.g., several of the packages discussed in Sections 12.3 and 12.5).

11-7-7	$\left(\mathbf{E}_y \int_0^{t_\epsilon} L_{x,y^x(s)} \varphi(x) ds \right)$ $\left(\mathbf{E}_y \int_0^{t_\epsilon} L_{x,y^x(s)} \varphi(x) ds \right)$	<pre>\usepackage{amsmath} \left[\biggl(\mathbf{E}_y \int_0^{t_\text{\varepsilon}} L_{x, y^x(s)} \varphi(x) \, ds \biggr) \right] \bigskip\Large \left[\biggl(\mathbf{E}_y \int_0^{t_\text{\varepsilon}} L_{x, y^x(s)} \varphi(x) \, ds \biggr) \right]</pre>
--------	---	--

11.7.5 Radical movements

In standard \LaTeX , the placement of the index on a radical sign is sometimes not good. With `amsmath`, the commands `\leftroot` and `\uproot` can be used within the optional argument of the `\sqrt` command to adjust the positioning of this index.

¹ See Section 11.8.1 on page 209 for the various mathematical classes of symbols.

Positive integer arguments to these commands move the root index to the left and up, respectively, while negative arguments move it right and down. These arguments are given in terms of math units (see Section 11.7.7), which are quite small, so these commands are useful for fine adjustments.

$\sqrt[\beta]{k}$	$\sqrt[\beta]{k}$	$\sqrt[\beta]{k}$	<pre>\usepackage{amsmath} \[\sqrt[\beta]{k} \qquad \sqrt[\leftroot{2}\uproot{4}]{\beta}{k} \qquad \sqrt[\leftroot{1}\uproot{3}]{\beta}{k} \qquad\]</pre>	11-7-8
-------------------	-------------------	-------------------	--	--------

11.7.6 Ghostbusters™

To get math spacing and alignment “just right”, it is often best to make creative use of some of primitive \TeX ’s unique and sophisticated typesetting abilities. These features are accessed by a collection of commands related to `\phantom` and `\smash`; and they can be used in both mathematical and other text.

For instance, the large alignment example (Example 11-2-9 on page 136) uses lots of phantoms to get the alignment just right. Each of these phantoms produces an invisible “white box” whose size (width and total height plus depth) is determined by typesetting the text in its argument and measuring its size.

Conversely, the command `\smash` typesets its contents (in an LR-box) but then ignores both their height and depth, behaving as if they were both zero. The standard \LaTeX command `\hphantom` is a combination of these, producing the equivalent of `\smash{}`: an invisible box with zero height and depth but the width of the phantom contents.

The `\vphantom` command makes the width of the phantom zero but preserves its total height plus depth. An example is the command `\mathstrut`, which is defined as “`\vphantom{}`” so that it produces a zero-width box of height and depth equal to that of a parenthesis.

The `amsmath` package provides an optional argument for `\smash`, used as follows: `\smash[t]{...}` ignores the height of the box’s contents but retains the depth, while `[b]` ignores the depth and keeps the height. Compare these four lines, in which only the handling of \sqrt{y} varies:

$\sqrt{x} + \sqrt{y} + \sqrt{z}$	<pre>\usepackage{amsmath} \$\sqrt{x} + \sqrt{y} + \sqrt{z}\$ \\ \$\sqrt{x} + \sqrt{\mathstrut y} + \sqrt{z}\$ \\ \$\sqrt{x} + \sqrt{\smash{y}} + \sqrt{z}\$ \\ \$\sqrt{x} + \sqrt{\smash[b]{y}} + \sqrt{z}\$</pre>	11-7-9
----------------------------------	--	--------

To get the three radical signs looking pleasantly similar, it seems that the thing to do may be to give the y some extra height with a strut — but that makes things only worse! The best solution turns out to be to smash the bottom of the y (but not the whole of it!).

In the next example, the two case lines are spread too far apart due to the depth of the denominator in the first line and the superscript on the numerator of the large fraction in the second line.

11-7-10

$$f_p(x) = \begin{cases} \frac{1}{p} & x = p \\ \frac{\frac{(1-x)^{\frac{1}{2}}}{x - \sin(x-p)}}{\sqrt{1-p} \cos(x-p)} & x \neq p \end{cases}$$

```
\usepackage{amsmath}
\[ f_p (x) =
\begin{cases}
\frac{1}{p} & x = p \\
\frac{\frac{(1 - x)^{\frac{1}{2}}}{\{ x - \sin (x - p) \}}}{\{\sqrt{1 - p} \, \, \, \cos (x - p)\}} & x \neq p
\end{cases} \]
```

As the lines do not overlap if we bring them closer together, we can ask \LaTeX to disregard the depth of the p in the denominator on the first line and the top of the large fraction in the second line using bottom and top `\smash` commands. We also have to add an empty brace group because of the unfortunate optimization of \TeX to ignore the `\smash` if it is the only object in the fraction; see also page 203.

11-7-11

$$f_p(x) = \begin{cases} \frac{1}{p} & x = p \\ \frac{\frac{(1-x)^{\frac{1}{2}}}{x - \sin(x-p)}}{\sqrt{1-p} \cos(x-p)} & x \neq p \end{cases}$$

```
\usepackage{amsmath}
\[ f_p (x) =
\begin{cases}
\frac{1}{\smash[b]{p}} & x = p \\
\frac{\{\frac{(1 - x)^{\frac{1}{2}}}{\smash[t]{\{ x - \sin (x - p) \}}}\}}{\{\sqrt{1 - p} \, \, \, \cos (x - p)\}} & x \neq p
\end{cases} \]
```

This, of course, would bring the two lines in this example confusingly close together. For this reason we also add a `\strut` so that the numerator of the main fraction still appears to have a certain height (a `\mathstrut`, which has the dimensions of a parenthesis, would not produce enough extra space):

11-7-12

$$f_p(x) = \begin{cases} \frac{1}{p} & x = p \\ \frac{\frac{(1-x)^{\frac{1}{2}}}{x - \sin(x-p)}}{\sqrt{1-p} \cos(x-p)} & x \neq p \end{cases}$$

```
\usepackage{amsmath}
\[ f_p (x) =
\begin{cases}
\frac{1}{\smash[b]{p}} & x = p \\
\frac{\frac{(1 - x)^{\frac{1}{2}}}{\mathstrut \smash[t]{\{ x - \sin (x - p) \}}}}{\{\sqrt{1 - p} \, \, \, \cos (x - p)\}} & x \neq p
\end{cases} \]
```

As you probably realize, in this case a much simpler way to achieve the same effect is to request some negative vertical space between the case lines, e.g., using `\[-4pt]`. Nevertheless, some moderate use of smashing is often of benefit to such unbalanced displays.

You may also think that this only partly solves the issue with this display and that it would look better if there is a bit more vertical space in the main fraction. In that case you could try adding a strut to both its numerator and denominator. A `\mathstrut` is too small and would have no effect, and a text `\strut` is too large. For such cases `mathtools` offers `\xmathstrut`.

`\xmathstrut[bottom-enlarge]{enlarge}`

This produces a strut of the height and depth of a parenthesis in the current math style, e.g., smaller in a script or scriptscript situation. The mandatory *enlarge* argument defines the factor by which it is enlarged at the top and by default also at the bottom. If the optional *bottom-enlarge* is also given, it is used for bottom instead. Thus, `\xmathstrut[.1]{.2}` makes a strut that is 30% larger than a normal `\mathstrut` with 20% being added above. Using a value of 0 in an argument means that this part of the strut is not altered at all, while using a negative value shortens the strut (usually useful only for the top part).

The behavior is best explained in an example. We show different `\xmathstrut` commands inside a `\boxed` command and highlight its height and depth by showing a vertical blue rule that extends through the full size of the box (using `\vrule`).

```
\usepackage{color,mathtools} \setlength\fbboxrule{0pt}\setlength\fbboxsep{0pt}
\newcommand\xx[2]{\scriptscriptstyle #1\boxed{#2\color{blue}\vrule}\,}

$ (a) \xx{1}{\mathstrut}           % normal strut (size of parentheses)
    \xx{2}{\xmathstrut{0}}         % 0 gives normal strut
    \xx{3}{\xmathstrut{0.5}}       % add 50% at top + bottom (= 100% bigger)
    \xx{4}{\xmathstrut{0}{-0.2}}   % remove 20% from top, but keep bottom
    \xx{5}{\xmathstrut{0.3}{-1}}   % bottom 30% larger, no height
    \xx{6}{\xmathstrut{-0.5}} (z) $ % -> see explanation below ...
```

(a) $\left| \begin{array}{c} 1 \\ 2 \\ 3 \\ 4 \\ 5 \\ 6 \end{array} \right| (z)$

11-7-13

The setting for `\fbboxrule` and `\fbboxsep` in the example was made to prevent the `\boxed` command from adding its own rules or spaces. The reason that `-0.5` in the last line of the example does not remove the strut altogether is due to the fact that the top part of a strut is roughly 70% of the overall size. Thus, 20% remains, while in the bottom part `-0.3` would already remove everything.

Using `\xmathstrut`, we can now easily open up the parts of the fractions a bit to make them more readable; we used it three times with slightly different values — finding the most appropriate values may need some experimentation.

```
\usepackage{mathtools}

\[\ f_p(x) =
\begin{cases}
\frac{1}{p} & x = p \\
\frac{\frac{(1-x)^{\frac{1}{2}}}{x-\sin(x-p)}}{\sqrt{1-p}\cos(x-p)} & x \neq p
\end{cases}
```

```
\frac{\frac{\xmathstrut{.1} (1 - x)^{\frac{1}{2}}}{\xmathstrut{.25} x - \sin (x - p)}}{\xmathstrut{.3} \sqrt{1 - p} \, \, \cos (x - p)}
& x \neq p

\end{cases} \]
```

11-7-14

Another collection of examples illustrates a very common application of smashing: using a partial `\smash` to give fine control over the height of surrounding delimiters. It also shows that smashing can lead to problems because the real height of the line needs to be known; this is restored by `\vphantom`. In the following code, `\Hmjd` is the compound symbol defined by

```
\newcommand\Hmjd{\widetilde{\mathcal{H}^2}_{\text{MJD}}(\chi)}
```

To show the resulting vertical space we added some rules:

Appearance	Code	Comment
$\overline{(\widetilde{\mathcal{H}^2_{\text{MJD}}(\chi)})}$	<code>\left(\quad \quad \quad \{\Hmjd\} \quad \right)</code>	<i>Outer brackets too large</i>
$\overline{(\widetilde{\mathcal{H}^2_{\text{MJD}}(\chi)})}$	<code>\left(\quad \quad \smash{\Hmjd} \quad \right)</code>	<i>Outer brackets too small and rules too close</i>
$\overline{(\widetilde{\mathcal{H}^2_{\text{MJD}}(\chi)})}$	<code>\left(\smash[t]{\Hmjd} \right) \vphantom{\Hmjd}</code>	<i>Just right!</i>
$\overline{(\widetilde{\mathcal{H}^2_{\text{MJD}}(\chi)})}$	<code>\left(\smash[t]{\Hmjd} \right)</code>	<i>Both \vphantom and partial smash are needed</i>

A word of warning: in a few places, deficiencies in the very low-level T_EX processing may cause errors in the fine details of typesetting. These possibilities are of particular concern in mathematical layouts where (1) a subformula (such as the numerator/denominator of a fraction or subscripts/superscripts) consists of exactly one LR-box, or a similarly constructed mathematical box, and also (2) that box does not have its natural size, as with the more complex forms of `\makebox`, `smashes`, and some `phantoms`. As an example, look at the following:

 *Smashes being ignored by T_EX sometimes*

11-7-15

$$\begin{array}{l}
 \left[\begin{array}{l}
 \sqrt{\frac{a+b}{x_j}} \quad \sqrt{\frac{a+b}{x_j}} \quad \sqrt{\frac{a+b}{x_j}} \quad \sqrt{\frac{a+b}{x_j+b}} \\
 \backslash[\\
 \sqrt{\frac{a+b}{x_j}} \quad \sqrt{\frac{a+b}{\smash{x_j}}} \quad \sqrt{\frac{a+b}{\{\}\smash{x_j}}} \quad \sqrt{\frac{a+b}{\smash{x_j+b}}} \\
 \backslash]
 \end{array} \right]
 \end{array}$$

To shorten the depth of the radical, a `\smash` was added in the second radical, but without any effect. With an empty brace group (third radical), it suddenly worked. On the other hand, no workaround was needed for the fourth radical.¹ For the same reason, the `\strut` or an empty brace group was actually necessary in Example 11-7-11 on page 201 to see any effects from the second `\smash` command there. In summary, whenever you find that a `\smash` does not work, try adding an empty math subformula (from `{}`) before the lonely box, to keep it from being mistreated.

¹Technically this is due to the denominator being wider than the numerator in this case so that it was not reboxed by T_EX.

Positive Spaces			Negative Spaces			Amount	
Short	Space	Long	Short	Space	Long	Math	Text
$\backslash,$		<code>\thinspace</code>	$\backslash!$		<code>\negthinspace</code>	3mu	0.1667em
$\backslash:$		<code>\medspace</code>			<code>\negmedspace</code>	4mu plus 2mu minus 4mu	0.2222em
$\backslash;$		<code>\thickspace</code>			<code>\negthickspace</code>	5mu plus 5mu	0.2777em
		<code>\enskip</code>				0.5em	
		<code>\quad</code>				1em	
		<code>\qquad</code>				2em	

Note: The “Amount” columns are discussed in the text.

Table 11.8: Mathematical spacing commands

robust, and they can also be used outside math mode in normal text. They are related to the thin, medium, and thick spaces available on the machines used to typeset mathematics in the mid-20th century.

If used in text mode, the amount of space added by these `\. . space` commands is based on fractions of 1em as listed in the rightmost column of the table. However, if used in math mode, the amounts are, in fact, defined by the current values of the three parameters `\thinmuskip`, `\medmuskip`, and `\thickmuskip`; the table lists their default values with `amsmath`. These very low-level T_EX parameters require values in “mu” (*math units*). They must therefore be set only via low-level T_EX assignments (as shown in Example 11-8-2 on page 210) and not by `\setlength` or similar commands. Moreover, in normal circumstances their values should not be modified because they are used internally by T_EX’s mathematical typesetting (see Table 11.9 on page 210).

Do not change the *muskip* parameter values

One math unit (1mu) is 1/18 of an em in the current mathematical font size (see also Table A.1 on page 652). Thus, the absolute value of a math unit varies with the mathematical style, giving consistent spacing whatever the style.

These math units can be used more generally to achieve even better control over space within mathematics. This is done via the `amsmath` command `\mspace`, which is like `\hspace` except that it can be used only within mathematics, and its length argument must be given in math units (e.g., `\mspace{0.5mu}`). Thus, while a `\quad` in a mathematical formula always produces the same space of 1em based on the main mathematical font size, specifying `\mspace{18mu}` produces a space that is about two-thirds the space in a double subscript size. This is shown in the next example, where different em-based spaces are used in the first and second line and then corresponding mu-based spaces are used in the third line.

11-7-18

		<code>\usepackage[fleqn]{amsmath}</code>
		<code>\begin{gather}</code>
$X a b c d$	(1)	<code>X \, a \enspace b \quad c \quad\quad d</code>
$X_{y a b c d}$	(2)	<code>X_{y_{f a} \enspace b \quad c \quad\quad d}}</code>
$X_{y a b c d}$	(3)	<code>X_{y_{f a} \mspace{9mu} b \mspace{18mu} c \mspace{36mu} d}}</code>
		<code>\end{gather}</code>

11.7.8 `resizegather` — Downscaling an equation

Sometimes a formula is just a tiny bit too large to fit the text width, as is the case with the next example, which is quite ugly looking:

$a + b + c + d + e + f + g = X$ <p style="text-align: center;">(1)</p> $a + b + c + d + e + f + g + h = Y$ <p style="text-align: center;">(2)</p>	<pre>\usepackage{amsmath} \begin{gather} a+b+c+d+e+f+g = X \\ a+b+c+d+e+f+g+h = Y \end{gather}</pre>	11-7-19
---	---	---------

In such a case you have the option of manually breaking the formula over two lines, but usually that does not work well when the excess width is only small, because then both lines are fairly empty. As an alternative, Heiko Oberdiek developed the package `resizegather` that redefines `gather`, `equation`, and their starred forms (but not `\[...]`) so that they scale down the formula in each line to fit into the available space.

Usually this is preferable to a split of the line, but only when the excess is small. Therefore, if it is larger than 5%, a warning is given, and you better visually verify that the result is acceptable. With the package option `warningthreshold`, you can alter the default. In the example we increase it to 10% to get only warnings for substantial resizing.

$a + b + c + d + e + f + g = X$ <p style="text-align: center;">(1)</p> $a + b + c + d + e + f + g + h = Y$ <p style="text-align: center;">(2)</p>	<pre>\usepackage[warningthreshold=.1]{resizegather} \begin{gather} a+b+c+d+e+f+g = X \\ a+b+c+d+e+f+g+h = Y \end{gather}</pre>	11-7-20
---	---	---------

In the previous example the first line is fine (correcting Example 11-7-19), but the second line in direct comparison becomes too tiny, and you get the following warning on the terminal

```
Package resizegather Warning: Equation line 2 is too large by 20.54451pt
(resizegather)                in environment 'gather' on input line 25.
```

to alert you about this fact so that you can take manual actions.

11.7.9 `subdepth` — Normalizing subscript positions

Subscripts in formulas are not always placed at the same vertical position by the $\text{T}_{\text{E}}\text{X}$ engine. Instead, their placement depends on surrounding conditions: if there is also a superscript, then $\text{T}_{\text{E}}\text{X}$ lowers the subscript slightly in order to leave enough space between the two. If you compare the different subscripts in

$$X_a = Y_b \geq Z_c^2 \qquad \text{C}_2\text{H}_5^+$$

you see that the c is lower than a or b . This is usually fine and desirable, but there are applications, for example, when typesetting chemical formulas, where it is preferable if all subscripts are properly aligned; e.g., the 2 is in the same position as the 5.

To help with this task, Donald Arseneau wrote a short piece of code that later got packaged by Will Robertson as `subdepth`. All you have to do is to load this package in order to get all subscripts in *all* formulas aligned.

11-7-21

$$X_a = Y_b \geq Z_c^2 \quad C_2H_5^+$$

```
\usepackage{subdepth}
\l[   X_a = Y_b \ge Z^2_c           \qqquad
      \mathrm{C}_2 \mathrm{H}_5^+   \r]
```

If you look carefully, you see that this not only aligns the subscripts but also slightly raises the superscripts in certain situations (e.g., in Z_c^2). If you do not like that aspect of the package behavior, load it with the package option `low-sup`.

11.7.10 Color in formulas

If you prepare educational material, but also in other situations, it is sometimes helpful if parts of a formula are highlighted, e.g., by using color. Even though color is not a concept natively available in \TeX (and therefore needs to be handled by the backend, for example, in the Portable Document Format (PDF) generation), it is fairly easy to color parts of a formula without any negative side effects to spacing as long as you avoid a few traps.

To color a complete formula, all you need to do is to place the whole formula inside `\textcolor`. It is also possible to use `\color` inside the formula for this purpose, but this may color less than you intended if you place the command in a place with a restricted scope, e.g., between `\left` and `\right` or into one of the `amsmath` display environments, because in there the scope ends at the next `&` or the end of the line. In either case, the color is automatically reset when the scope ends.

11-7-22

What is $(a+b)(a-b)$?

$$(a+b)^2 = a^2 + 2ab + b^2$$

$$(a-b)^2 = a^2 - 2ab + b^2$$

```
\usepackage{amsmath,color}
What is \textcolor{blue}{$(a+b)(a-b)$}?
\begin{align*}
\color{blue} (a+b)^2 &= a^2 + 2ab + b^2 \\
(a-b)^2 &= a^2 \color{blue}- 2ab + b^2 \end{align*}
```

While you can put whole formulas inside `\textcolor`, you should not use it inside a math formula, because this usually results in bad spacing as shown in the next example where the binary minus suddenly comes out as a unary minus — a defect that does not happen with `\mathcolor` that was designed for this.

Thus, if you want to color only parts of a formula, you have two options: either change the color back and forth using several `\color` commands (which is fairly cumbersome and on some occasions results in spacing problems or even errors) or, assuming you have a recent \TeX release, use `\mathcolor` inside the formula.

Here is an example for comparison:

$(a+b)^2 = a^2 + 2ab + b^2$ $(a-b)^2 = a^2 - 2ab + b^2$ <p>But don't do this:</p> $(a-b)^2 = a^2 - 2ab + b^2$	<pre>\usepackage{amsmath,color} \begin{align*} (a+b)^2 &= a^2 \color{blue}{+2ab}\color{black}{+ b^2} \\ (a-b)^2 &= a^2 \mathcolor{blue}{-2ab} + b^2 \\ \intertext{But don't do this:} (a-b)^2 &= a^2 \textcolor{blue}{-2ab} + b^2 \end{align*}</pre>	11-7-23
---	--	---------

As you see, using `\mathcolor` is much simpler than trying to alter the color with `\color`, and it is designed to work correctly even in far more complicated cases, e.g., when coloring just a large operator but not its limits¹ or coloring an opening or closing symbol made with `\left` or `\right`². With `\mathcolor` all this is easy, so it should be the preferred choice.

It preserves the nature of the math symbols inside of its argument and allows them to interact correctly with their uncolored neighbors, which explains why the spacing around the equal sign in the next example, or the minus in the previous one, remains correct. It also understands about subscripts and superscripts and puts the color changes in appropriate places in order to not affect their placement.

$\sum_{i=1}^n x_i = \left\{ \frac{1}{2} \right\}^{\alpha+\beta}$	<pre>\usepackage{color} \[\mathcolor{blue}{\sum}_{i=1}^n x_i \mathcolor{blue}{= \left\{ \frac{1}{2} \right\}^{\alpha+\beta}} \]</pre>	11-7-24
--	--	---------

The `\mathcolor` commands can be nested as exhibited in the next example where the integral and its upper limit (but not its lower) are in black, while the rest of the formula, except for the `\dotsb`, is in blue.

$a + b + \int_0^1 f(x) dx + \dots$	<pre>\usepackage{amsmath,color} \[\mathcolor{blue}{a + b + \mathcolor{black}{\int^1_0 f(x)\,dx + }} \dotsb \]</pre>	11-7-25
------------------------------------	--	---------

What `\mathcolor` cannot do for you is to color across boundaries of \LaTeX 's or `amsmath`'s display environments; i.e., you cannot place an `&` or a `\\` inside the argument of `\mathcolor`. Instead, you have to color each part of such display environments separately — unless you want to color the whole formula, in which case you can place it inside `\textcolor`.

11.8 Symbols in formulas

The tables at the end of this section advertise the large range of mathematical symbols provided by the \mathcal{AMS} font packages, including the command to use for each symbol. They also include the supplementary symbols from the St. Mary Road Font, which

¹This needs four `\color` commands and extra braces in the sub and superscripts — try it out.

²This is simply not possible with `\color` unless you color both — again a good exercise to try.

was designed by Alan Jeffrey and Jeremy Gibbons. This font extends the Computer Modern and \mathcal{AMS} symbol font collections; the corresponding `stmaryrd` package should normally be loaded in addition to `amssymb`, but always after it. It provides extra symbols for fields such as functional programming, process algebra, domain theory, linear logic, and many more. For a wealth of information about an even wider variety of symbols, see the *Comprehensive L^AT_EX Symbol List* by Scott Pakin [161].

The tables indicate which extra packages need to be loaded to use each symbol command. They are organized as follows: symbols with command names in black are available in standard L^AT_EX without loading further packages; symbols in blue require loading either `amsmath`, `amssymb`, or `stmaryrd`, as explained in the table notes. If necessary, further classification is given by markings: *(StM)* signals a symbol from `stmaryrd` when the table also contains symbols from other packages; *(kernel)* identifies symbols that are available in standard L^AT_EX but only by combining two or more glyphs, whereas a single glyph exists in the indicated package; and *(var)* marks “Alphabetic characters/symbols” (of type `\mathalpha`; see Table 9.20 on page 751) that change appearance when used within the scope of a math alphabet identifier (see Section 9.4).

11.8.1 Mathematical symbol classes

The symbols are classified primarily by their “mathematical class”, occasionally called their “math symbol type”. This classification is related to their “meaning” in standard technical usage, but its importance for mathematical typography is that it influences the layout of a formula. For example, T_EX’s mathematical formatter adjusts the horizontal space on either side of each symbol according to its mathematical class. There are also some finer distinctions made, for example, between accents and simple symbols and in breaking up the enormous list of Relation symbols into several tables.

The setup for mathematics puts each symbol into one of these classes: Ordinary (Ord), Operator (Op), Binary (Bin), Relation (Rel), Opening (Open), Closing (Close), or Punctuation (Punct). This classification can be explicitly changed by using the commands `\mathord`, `\mathop`, `\mathbin`, `\mathrel`, `\mathopen`, `\mathclose`, and `\mathpunct`, thereby altering the surrounding spacing. In the next example, `\#` and `\top` (both Ord by default) are changed into a Rel and an Op:

11-8-1

$$a \# \top_x^\alpha x_b^\alpha$$

$$a \# \top_x^\alpha x_b^\alpha$$

```
\usepackage[fleqn]{amsmath}
\[ a \# \top_x^\alpha x_b^\alpha \]
\[ a \mathrel{\#} \mathop{\top}_x^\alpha x_b^\alpha \]
```

A symbol can be declared to belong to one of the above classes using the mechanism described in Section 9.8.5. In addition, certain subformulas — most importantly fractions, and those produced by `\left` and `\right` — form a class called Inner; it is explicitly available through the `\mathinner` command.

In T_EX, spacing within formulas is done simply by identifying the class of each object in a formula and then adding space between each pair of adjacent objects as

		<i>Right Object</i>							
		Ord	Op	Bin	Rel	Open	Close	Punct	Inner
<i>Left Object</i>	Ord	0	1	(2)	(3)	0	0	0	(1)
	Op	1	1	*	(3)	0	0	0	(1)
	Bin	(2)	(2)	*	*	(2)	*	*	(2)
	Rel	(3)	(3)	*	0	(3)	0	0	(3)
	Open	0	0	*	0	0	0	0	0
	Close	0	1	(2)	(3)	0	0	0	(1)
	Punct	(1)	(1)	*	(1)	(1)	(1)	(1)	(1)
	Inner	(1)	1	(2)	(3)	(1)	0	(1)	(1)

0 = no space, 1 = \thinmuskip, 2 = \medmuskip, 3 = \thickmuskip, * = impossible
Entries in (blue) are not added when in the mathematical “script styles” (see also Sections 11.7.1 and 11.7.7).

Table 11.9: Space between symbols

defined in Table 11.9; this table is unfortunately hardwired into TeX’s mathematical typesetting routines and so cannot be changed by macro packages.¹ In this table 0, 1, 2, and 3 stand for no space, a thin space (\,), a medium space (\:), and a thick space (\;), respectively. The exact amounts of space used are listed in Section 11.7.7 on page 204.

A Binary symbol is turned into an Ordinary symbol whenever it is not preceded and followed by symbols of a nature compatible with a binary operation; for this reason, some entries in the table are marked with a star to indicate that they are not possible. For example, \$+x\$ gives $+x$ (a “unary plus”) and not $+x$; the latter can be produced by $\${}\!+x\$$.

Finally, an entry in (blue) in Table 11.9 indicates that the corresponding space is not inserted when the style is script or scriptscript.

As an example of applying these rules, consider the following formula (the default values are deliberately changed to show the added spaces more clearly):

$$a - b = -\max\{x, y\} \quad \begin{array}{l} \text{\textcolor{blue}{\thinmuskip=10mu \medmuskip=17mu \thickmuskip=30mu}} \\ \text{\textcolor{blue}{\left[a - b = -\max \left\{ x, y \right\} \right]}} \end{array} \quad \boxed{11-8-2}$$

TeX identifies the objects as Ord, Bin, Ord, Rel, and so on, and then inserts spaces as follows:

$$\begin{array}{ccccccc} a & - & b & = & - & \max & \{ & x & , & y & \} \\ \text{Ord} \backslash & & \text{Bin} \backslash & & \text{Ord} \backslash & & \text{Rel} \backslash & & \text{Ord} \backslash & & \text{Op} & \text{Open} & \text{Ord} & \text{Punct} & \backslash & \text{Ord} & \text{Close} \end{array}$$

The minus in front of \max is turned into an Ordinary because a Binary cannot follow a Relation.

¹Although a few of the entries in the table are questionable, on the whole it gives pleasing results.

Table 11.9 reveals a difference¹ between a “\left...\right” construction, in which the entire subformula delimited by the construction becomes a single object of class Inner (see Section 11.5.6 on page 191) and commands like \Bigl and \Bigr that produce individual symbols of the classes Opening and Closing, respectively. Although they may result in typesetting delimiters of equal vertical size, spacing differences can arise depending on adjacent objects in the formula. For example, Ordinary followed by Opening gets no space, whereas Ordinary followed by Inner is separated by a thin space. In the next example we again use larger spaces to highlight these differences:

 Possible spacing issues with \left and \right

11-8-3

$a\left(\sum x\right) \neq a\left(\sum x\right)$ $\sin(x^2), x \neq \sin(x^2), x$	<pre> \thinmuskip=10mu \medmuskip=15mu \thickmuskip=20mu \[a \Bigl(\sum x \Bigr) \neq a \left(\sum x \right) \] \[\sin(x^2), x \neq \sin\left(x^2\right), x \]</pre>
---	--

The spaces inside the subformula within a “\left...\right” construction are as expected, beginning with an Opening symbol and ending with a Closing symbol. However, especially with the $\sin(x^2)$ example the extra spaces are not correct, and to avoid this problem, you can use the commands \mleft and \mright from the mleftright package (written by Heiko Oberdiek) in their place. Here we repeat the previous examples using these commands:

11-8-4

$a\left(\sum x\right) = a\left(\sum x\right)$ $\sin(x^2), x \simeq \sin(x^2), x$	<pre> \usepackage{mleftright} \thinmuskip=10mu \medmuskip=15mu \thickmuskip=20mu \[a \Bigl(\sum x \Bigr) = a \mleft(\sum x \mright) \] \[\sin(x^2), x \simeq \sin\mleft(x^2\mright), x \]</pre>
--	---

In fact, you can even change the meanings of \left and \right to locally (or globally) act as Opening and Closing symbols by executing \mleftright and \mleftrightrestore to get the original T_EX definitions back.

In summary, it is not enough to look up a symbol in the tables that follow; rather, it is also advisable to check that the symbol has the desired mathematical class to ensure that it is properly spaced when used. Example 11-8-5 on page 214 shows how to define new symbols that differ only in their mathematical class from existing symbols.

11.8.2 Letters, numerals, and other Ordinary symbols

The unaccented ASCII Latin letters and arabic numeral digits (see Table 11.10) are referred to as “Alphabetic symbols”. The font used for them can vary: in mathematical formulas, the default font for Latin letters is italic, whereas for the arabic digits it is upright/roman. Alphabetical symbols are all of class Ordinary.

Unlike the Latin letters, the mathematical Greek letters are no longer closely related to the glyphs used for typesetting normal Greek text. Due to an interesting 18th

¹Another important distinction is that the material within a “\left...\right” construction is processed separately as a subformula (see Section 11.7.2 on page 197).

<i>A B C D E F G H I J K L M N O P Q R S T U V W X Y Z</i>

Symbols in *blue* require the `amssymb` package. *(var)* indicates a variable Alphabetic symbol.

Table 11.11: Symbols of class `\mathord` (Greek)

century happenstance, in the major European tradition of mathematical typography the default font for lowercase Greek letters in mathematical formulas is italic, whereas for uppercase Greek letters it is upright/roman. (In other fields, such as physics and chemistry, the typographical traditions are slightly different.)

The capital Greek letters in the first rows of Table 11.11 are also Alphabetic symbols whose font varies, with the default being upright/roman. Those capital Greek letters not present in this table are the letters that have the same appearance as some Latin letter (e.g., *A* and *Alpha*, *B* and *Beta*, *K* and *Kappa*, *O* and *Omicron*). Similarly, the list of lowercase Greek letters contains no omicron because it would be identical in appearance to the Latin *o*. Thus, in practice, the Greek letters that have Latin look-alikes are not used in mathematical formulas.

Table 11.12 on the facing page lists other letter-shaped symbols of class Ordinary. The first four are Hebrew letters. Table 11.13 lists the remaining symbols in the Ordinary class, including some common punctuation. These behave like letters and digits, so they never get any extra space around them.

A common mistake is to use the symbols from Table 11.13 directly as Binary operator or Relation symbols, without using a properly defined math symbol command for that type. Thus, if you use commands such as `\#`, `\square`, or `\&`, check carefully that you get the correct inter-symbol spaces or, even better, define your own symbol command, which can be done with `\DeclareMathSymbol`, which is explained in Section 9.8.5 on page 750.

\aleph	<code>\aleph</code>	\beth	<code>\beth</code>	\daleth	<code>\daleth</code>	\gimel	<code>\gimel</code>

\DeclareMathSymbol\square{\mathrel}{AMSa}{"03}
\thickmuskip=10mu plus 5mu

\noindent Symbols of wrong class (ord):
\[ a \neg b \quad \quad \quad x \square y + z \]
Manual correction:
\[ a \mathbin{\neg} b \quad \quad \quad x \mathrel{\square} y + z \]
Symbols of correct class:
\[ a \neg b \quad \quad \quad b \quad \quad \quad x \square y + z \]
```

11-8-5

11.8.3 Mathematical accents

The basic accent commands available for use in formulas are listed in Table 11.14. Most of them are already defined in standard \LaTeX . See Section 11.4.12 for ways to define additional accent commands and ways to make compound accents and Section 11.5.2 for information about extensible accents. Adding a mathematical accent to a symbol always produces a symbol of class Ordinary. Thus, without additional help from `\mathbin` or `\mathrel`, one cannot use the accents to produce new Binary or Relation symbols.

$a = b$ but $a \approx b$ which is not $a \approx b$	<pre> \usepackage{amsmath} \[a = b \text{ but } a \tilde{=} b \text{ which is not } a \mathrel{\tilde{=}} b \]</pre>
--	---

11-8-6

Other ways to place symbols over Relation symbols are shown in Section 11.4.14.

11.8.4 Binary operator symbols

There are more than 100 symbols of class Binary operator from which to choose. Most of these Binary symbols are shown in Table 11.15 on the next page. Some of

*	* or \ast	+	+	−	−
II	\amalg	Φ	\baro ^(StM)	⌋	\barwedge
∥	\bbslash ^(StM)	▽	\bigtriangledown	△	\bigtriangleup
⌚	\Cap or \doublecap	∩	\cap	⊔	\Cup or \doublecup
∪	\cup	∨	\curlyvee	⋈	\curlywedge
†	\dag or \dagger	‡	\ddag or \ddagger	◇	\diamond
÷	\div	*	\divideontimes	+	\dotplus
∥	\fatbslash ^(StM)	;	\fatsemi ^(StM)	//	\fatslash ^(StM)
>	\gtrdot	⌈	\intercal		\interleave ^(StM)
∧	\land or \wedge	⌋	\lbag ^(StM)	◁	\leftslice ^(StM)
↗	\leftthreetimes	≤	\lessdot	∨	\lor or \vee
×	\ltimes	⋈	\merge ^(StM)	⊖	\minuso ^(StM)
±	\moo ^(StM)	⊞	\mp	⊕	\nplus ^(StM)

∧	\wedge	⌋	\wr	Y	\Ydown ^(StM)
←	\Yleft ^(StM)	→	\Yright ^(StM)	Y	\Yup ^(StM)

Symbols in *blue* require either the `amssymb` package or, if flagged with ^(StM), the `stmaryrd` package.

The left and right triangles are also available as Relation symbols.

The `stmaryrd` package confusingly changes the Binary symbols `\bigtriangleup` and `\bigtriangledown` into Operators, leaving only the synonyms `\varbigtriangleup` and `\varbigtriangledown` for the Binary operator forms.

Table 11.15: Symbols of class `\mathbin` (miscellaneous)

⊠	\boxast ^(StM)	▣	\boxbar ^(StM)	⊞	\boxbox ^(StM)	⊠	\boxbslash ^(StM)
⊞	\boxcircle ^(StM)	⊞	\boxdot	□	\boxempty ^(StM)	⊞	\boxminus
⊞	\boxplus	⊞	\boxslash ^(StM)	⊞	\boxtimes	□	\oblong ^(StM)

All symbols require either the `amssymb` package or, if flagged with ^(StM), the `stmaryrd` package.

Table 11.16: Symbols of class `\mathbin` (boxes)

them are also available, under different names, as Relation symbols. The `amssymb` package offers a few box symbols for use as Binary operators; many more are added by `stmaryrd`. These are shown in Table 11.16.

○ <code>\bigcirc</code>	⊗ <code>\oast^(StM)</code> or <code>\circledast^(StM)</code>	⊖ <code>\obar^(StM)</code>
○ <code>\varbigcirc^(StM)</code>	⊗ <code>\varoast^(StM)</code>	⊖ <code>\varobar^(StM)</code>
⊗ <code>\obslash^(StM)</code>	○ <code>\ocircle^(StM)</code> or <code>\circledcirc^(StM)</code>	⊙ <code>\odot</code>
⊗ <code>\varobslash^(StM)</code>	⊙ <code>\varocircle^(StM)</code>	⊙ <code>\varodot^(StM)</code>
⊗ <code>\ogreaterthan^(StM)</code>	⊗ <code>\olessthan^(StM)</code>	⊖ <code>\ominus</code>
⊗ <code>\varogreaterthan^(StM)</code>	⊗ <code>\varolessthan^(StM)</code>	⊖ <code>\varominus^(StM)</code>
⊕ <code>\oplus</code>	⊗ <code>\oslash</code>	⊗ <code>\otimes</code>
⊕ <code>\varoplus^(StM)</code>	⊗ <code>\varoslash^(StM)</code>	⊗ <code>\varotimes^(StM)</code>
⊖ <code>\ovee^(StM)</code>	⊖ <code>\owedge^(StM)</code>	⊖ <code>\varovee^(StM)</code>
⊖ <code>\varowedge^(StM)</code>	• <code>\bullet</code>	• <code>\cdot</code>
• <code>\centerdot</code>	○ <code>\circ</code>	⊖ <code>\circleddash</code>

Symbols in blue require either the `amssymb` package or, if flagged with ^(StM), the `stmaryrd` package.

Option `heavycircles` of the `stmaryrd` package affects all commands starting with `\var` and their normal variants.

Table 11.17: Symbols of class `\mathbin` (circles)

The `stmaryrd` package can be loaded with the option `heavycircles`. It causes each circle symbol command in Table 11.17 that starts with `\var` to swap its definition with the corresponding command without the “`var`”; for example, the symbol `\varodot` becomes `\odot`, and vice versa.

11.8.5 Relation symbols

The class of binary Relation symbols forms a collection even larger than that of the Binary operators. The lists start with symbols for equality and order (Table 11.18 on the next page). You can put a slash through any Relation symbol by preceding it with the `\not` command; this negated symbol represents the complement (or negation) of the relation.

$u \not\leq v$ or $a \notin A$ `$ u \not< v$` or `$a \not\in \mathbf{A}$`

11-8-7

Especially with larger symbols, this generic method of negating a Relation symbol does not always give good results because the slash will always be of the same size, position, and slope. Therefore, some specially designed “negated symbols” are also available (see Table 11.19 on the facing page). If a choice is available, the designed glyphs are usually preferable. To see why, compare the symbols in this example.

$\not\leq$ $\not\geq$ $\not\sim$ `\usepackage{amssymb}`
 $\not\leq$ $\not\geq$ $\not\sim$ `$ \not\leq \ \ \not\succeq \ \ \not\sim \ $ \par`

\therefore is a Relation symbol, so its spacing may not be as expected in common uses.

Table 11.26: Symbols of class `\mathrel` (miscellaneous)

In addition to `\not`, used to negate general Relation symbols, other building blocks have been especially designed to negate or extend arrow-like symbols; these are collected in Table 11.24.

11-8-11 \longleftrightarrow \leftrightarrow `\usepackage{stmaryrd}`
`$\Longarrownot\longlefttrightarrow \qqquad \arrownot\hookleftarrow$`

Table 11.25 shows Relation symbols that involve one or two colons. They are provided if you load the package `colonequals` by Heiko Oberdiek. The symbols are constructed from other glyphs; e.g., `\colonequals` is made up from a colon and an equal sign with some negative space between the two and can therefore be used with different math font setups. To fine-tune the constructed symbols, the commands `\colonsep` and `\doublecolonsep` can be adjusted (with `\renewcommand`).

Finally, in Table 11.26 you will find a miscellaneous collection of Relation symbols provided by the kernel or `amssymb`.

$\int \int$ <code>\int</code>	$\oint \oint$ <code>\oint</code>	$\square \square$ <code>\bigbox^(StM)</code>
$\cap \cap$ <code>\bigcap</code>	$\cup \cup$ <code>\bigcup</code>	$\Upsilon \Upsilon$ <code>\bigcurlyvee^(StM)</code>
$\wedge \wedge$ <code>\bigcurlywedge^(StM)</code>	$\ \ \ $ <code>\biginterleave^(StM)</code>	$\oplus \oplus$ <code>\bignplus^(StM)</code>
$\odot \odot$ <code>\bigodot</code>	$\oplus \oplus$ <code>\bigoplus</code>	$\otimes \otimes$ <code>\bigotimes</code>
$\ \ \ $ <code>\bigparallel^(StM)</code>	$\sqcap \sqcap$ <code>\bigsqcap^(StM)</code>	$\sqcup \sqcup$ <code>\bigsqcup</code>
$\nabla \nabla$ <code>\bigtriangledown</code>	$\triangle \triangle$ <code>\bigtriangleup</code>	$\uplus \uplus$ <code>\biguplus</code>
$\vee \vee$ <code>\bigvee</code>	$\wedge \wedge$ <code>\bigwedge</code>	$\coprod \coprod$ <code>\coprod</code>
$\prod \prod$ <code>\prod</code>	$\int \int$ <code>\smallint</code>	$\sum \sum$ <code>\sum</code>

Operator symbols in *blue* require the `stmaryrd` package.

The `stmaryrd` package confusingly changes the Binary symbols `\bigtriangleup` and `\bigtriangledown` into Operators, but there are alternative commands for the Binary operator forms.

Note that `\smallint` does not change size.

Further integral operators are provided by the `esint` package; see Section 11.4.6 on page 169.

Table 11.27: Symbols of class `\mathop`

11.8.6 Operator symbols

The Operator symbols typically come in two sizes, for text and display uses; most of them are related to similar Binary operator symbols. Whether an Operator symbol takes limits in displays depends on a variety of factors (see Section 11.4.4). The available collection is shown in Table 11.27.

11.8.7 Punctuation

The symbols of class Punctuation appear in Table 11.28, together with some other punctuation-like symbols. Note that some of the typical punctuation characters (i.e., “ . ! ? ”) are not set up as mathematical punctuation but rather as symbols of class Ordinary. This can cause unexpected results for common uses of these symbols, especially in the cases of ! and ?. Some of the dots symbols listed here are of class Inner; Section 11.5.1 on page 180 provides information about using dots for mathematical ellipsis.

The `:` character produces a colon with class Relation — not a Punctuation symbol. As an alternative, standard \LaTeX offers the command `\colon` as the Punctuation

,	,	...	<code>\cdots</code> ^(inner)	...	<code>\hdots</code> ^(inner)	...	<code>\ldots</code> ^(inner)	...	<code>\mathellipsis</code> ^(inner)
;	;	:	<code>\colon</code>	⋯	<code>\ddots</code> ^(inner)	⋮	<code>\vdots</code> ^(ord)		

Punctuation symbols in *blue* require the `amsmath` package.
 The logical `amsmath` commands normally used to access `\cdots` and `\ldots` are described in Section 11.5.1.
 The `\colon` command is redefined in `amsmath`, making it unsuitable for use as a general punctuation character.
 Synonyms: ... `\hdots`, `\ldots` ... `\mathellipsis`, `\ldots`

Table 11.28: Symbols of class `\mathpunct`, `\mathinner`, `\mathord` (punctuation)

<code>[]</code>	<code>[]</code> or <code>\lbrack \rbrack</code>	<code>{ }</code>	<code>\{ \}</code> or <code>\lbrace \rbrace</code>	<code>()</code>	<code>()</code>
<code>< ></code>	<code>\langle \rangle</code>	<code>\lceil \rceil</code>	<code>\lceil \rceil</code>	<code>\lfloor \rfloor</code>	<code>\lfloor \rfloor</code>
<code>()</code>	<code>\lgrou p \rgrou p</code>	<code>\l moustache \rmoustache</code>	<code>\l moustache \rmoustache</code>	<code>\lvert \rvert</code>	<code>\lvert \rvert</code>
<code>\lVert \rVert</code>	<code>\lVert \rVert</code>	<code>\llbracket \rrbracket</code> ^(StM)	<code>\llbracket \rrbracket</code> ^(StM)		

Delimiters in *blue* require either the `amsmath` package or, if flagged with ^(StM), the `stmaryd` package.
 Delimiters `\lgrou p`, `\rgrou p`, `\l moustache`, and `\rmoustache` are available only in sizes greater than `\big`.

Table 11.29: Symbol pairs of class `\mathopen` and `\mathclose` (extensible)

symbol. However, the `amsmath` package makes unfortunate major changes to the spacing produced by the command `\colon` so that it is useful only for a particular layout in constructions such as `f\colon A\to B` where it produces $f: A \rightarrow B$. It is therefore wise to always use `\mathpunct{ : }` for the simple punctuation colon in mathematics.

11.8.8 Opening and Closing symbols

The paired extensible delimiters, when used on their own (i.e., without a preceding `\left`, `\right`, or `\middle`), produce symbols of class Opening or Closing; these pairs are listed in Table 11.29. See Section 11.5.6 on page 191 for further information about the extensible symbols.

\llcorner	<code>\llcorner</code>	\lrcorner	<code>\lrcorner</code>	\ulcorner	<code>\ulcorner</code>	\urcorner	<code>\urcorner</code>
\lceil	<code>\lceil</code>	\rceil	<code>\rceil</code>	$\mathbin{\&}$	<code>\binampersand</code>	$\mathbin{\&}$	<code>\bindnasrepma</code>
\lfloor	<code>\lfloor</code>	\rfloor	<code>\rfloor</code>	$\{$	<code>\Lbag</code>	$\}$	<code>\Rbag</code>
\llbracket	<code>\llbracket</code>	\rrbracket	<code>\rrbracket</code>	\langle	<code>\llparenthesis</code>	\rangle	<code>\rrparenthesis</code>

Symbols on the first line require the `amssymb` package; all others the `stmaryd` package. They are not extensible.

Table 11.30: Symbol pairs of class `\mathopen` and `\mathclose` (nonextensible)

To improve the flexibility of the vertical bar notation, `amsmath` defines some new pairs of paired extensible delimiter commands: `\lvert`, `\rvert`, `\lVert`, and `\rVert`. These commands are comparable to standard \LaTeX 's `\langle` and `\rangle` commands.

Finally, there are a few nonextensible paired symbols of class Opening and Closing, as listed in Table 11.30. They should not be used after `\left` or `\right`.

CHAPTER 12

Fonts in Formulas

12.1 The world of (Latin) math alphabets	226
12.2 Making it bold	235
12.3 Traditional math font setup through packages.	238
12.4 unicode-math — Using Unicode math fonts	253
12.5 A visual comparison of different math setups	261

For most symbols in a formula, the font used for a glyph cannot be changed by a font declaration as it can be in text. Indeed, there is no concept of, for example, an italic plus sign or a small capital less than sign.

One exception involves the letters of the Latin alphabet, whose appearance can be altered by the use of math alphabet identifier commands such as `\mathcal`. The commands provided by standard \LaTeX for this purpose are discussed in Section 9.4; in the first section of this chapter we introduce a few more and discuss their use in some detail.

Another exception relates to the use of bold versions of arbitrary symbols to produce distinct symbols with new meanings. This potentially doubles the number of symbols available, as boldness can be a recognizable attribute of a glyph for nearly every shape: depending on the font family, even “<” is noticeably different from “<”. Although there is a `\mathbf` command, the concept of a math alphabet identifier cannot be extended to cover bold symbols — better solutions are the topic of the second section.

To change the overall appearance of the mathematics in a document, the best approach is to replace all the fonts used to typeset formulas. This is usually done in the preamble of a document by loading a (set of) suitable packages, such as those discussed in Section 12.3 starting on page 238.

In the world of text fonts (Chapter 10) there is a clear separation between fonts suitable only for use with \pdfTeX and fonts for exclusive use in Unicode engines. Fonts for \pdfTeX are available as 8-bit fonts, encoded in OT1, T1, or some other 8-bit

font encoding from Table 9.18 on page 1737 and typically available as Type-1 or METAFONT fonts. In contrast, OpenType or TrueType fonts are usable only with \LaTeX or \LuaTeX and are encoded in the TU font encoding.^{1,2}

For symbol fonts this is not the case, at least in one direction: it is easily possible to use an 8-bit symbol font, e.g., MarVoSym, originally designed for use with \pdfTeX , with one of the Unicode engines.

Given that formulas largely consist of fixed symbols together with a few alphabetical characters and that there have not been (many) Unicode fonts dedicated to mathematics (i.e., fonts that contain the mathematical symbols in their appropriate Unicode slots), it should come as no surprise that the Unicode engines have been designed to work with traditional \TeX math fonts.

This has changed in recent years, and while developing OpenType Math fonts (compared to Text fonts) remains a niche market, there are now a number of fonts available that make it interesting to provide a \LaTeX math setup that directly uses such fonts. Such a setup is available with the `unicode-math` package by Will Robertson, and we will describe it in Section 12.4 on page 253.

In the final section of this chapter, starting at page 261, we showcase the effects of extensive changes to documents on a sample page of mathematics, made with just a few keystrokes. It uses the same input material typeset with both Computer Modern Math fonts (the default in \LaTeX) and nearly 50 other font family setups for text and mathematics. All of the fonts used are readily available and, except for Lucida fonts, provided free of charge.

12.1 The world of (Latin) math alphabets

It is easily possible to add additional new math alphabets for use in formulas. While this can be done using arbitrary command names, by convention `\mathcal` (a calligraphic alphabet), `\mathscr` (a script alphabet), `\mathfrak` (a fraktur alphabet), and `\mathbb` (a double-stroke also known as blackboard bold alphabet) are normally used as command names. Out of the box only `\mathcal` is available; for the others you have to add a suitable package (e.g., `mathalpha`) in the preamble or make a declaration manually using `\DeclareMathAlphabet`.

By loading the `amsfonts` (or the `amssymb`) package, both the Euler Fraktur alphabet by Hermann Zapf (`\mathfrak`) and a blackboard bold alphabet³ (`\mathbb`) become available.

$\forall n \in \mathbb{N} : \mathfrak{M}_n \leq \mathfrak{A}$ `\usepackage{amsfonts}`
`\$ \forall \text{forall } n \text{ \in } \mathbb{N} : \mathfrak{M}_n \leq \mathfrak{A}` \$

12-1-1

¹While it is possible to load 8-bit text fonts in Unicode engines, this is not a good idea because correct hyphenation depends on using the appropriate font encoding, which means that words with diacritics come out wrong if a legacy font encoding such as T1 is used.

²If text fonts are usable with all engines (and many are), then this is because somebody generated Type-1 fonts from Unicode fonts (restricting them to 8-bit and the appropriate encoding) or that somebody built an OpenType font from existing 8-bit sources.

³Not much is known about the origin of this alphabet. Research in old archives (thanks to Nelson Beebe, Barbara Beeton, and Ulrik Vieth for digging) produced no conclusive results.

If you also want to use upright Euler Script, you can load the `eucal` package that is also part of the `amsfonts` distribution. Loaded without options, it replaces the default `\mathcal`, but if loaded with the option `mathscr`, as done below, it becomes accessible as `\mathscr`, and `\mathcal` remains free for a different alphabet:

*The Euler Script font
by Hermann Zapf*

	$ABCDEFGHIJKLMN\mathcal{OPQRSTUVWXYZ}$	<code>\usepackage[mathscr]{eucal}</code>
		<code>\[\mathcal{ABCDEFGHIJKLMNOPQRSTUVWXYZ} \]</code>
12-1-2	$ABCDEFGHIJJKLMNOPQRSTUVWXYZ$	<code>\[\mathscr{ABCDEFGHIJKLMNOPQRSTUVWXYZ} \]</code>

If you prefer a geometric hollowed-out blackboard bold font in `\mathbb`, you can load, for example, the `bboldx` package that provides support for a font designed by Alan Jeffrey. One interesting aspect of this font is that it contains many more glyphs than the usual (Uppercase) alphabet[?], which even allows you to use it outside formulas by accessing it as `\usefont{U}{bboldx}{m}{n}` as we did here. Michael Sharpe added an additional thin and a bold face to the original font and made it available through the package `bboldx`.

*A double-stroke font
by Alan Jeffrey*

	$\mathbb{N} = \{0, 1, 2, 3, \dots\}$	<code>\usepackage[light]{bboldx}</code>
	$ABCDEFGHIJKLMN\mathbb{OPQRSTUVWXYZ}$	<code>\[\mathbb{N}=\{\mathbb{0},1,2,3,\ldots\} \]</code>
		<code>\[\mathbb{ABCDEFGHIJKLMN\mathbb{OPQRSTUVWXYZ}} \]</code>
12-1-3	$abcdefghijklmnpqrstuvwxy\mathbb{z}$	<code>\[\mathbbfbb{abcdefghijklmnpqrstuvwxy\mathbb{z}} \]</code>

By default the medium series is offered as `\mathbb`, while `\mathbbfbb` selects the bold series. If you load the package with the option `light`, you get the thin and medium series with the two commands instead. Alternatively, you can use `bfbb`, which forces the package to use the bold series for `\mathbf` as if bold were the regular weight. You can also easily scale the alphabet slightly to make it fit with other glyphs in your formulas by using the option `scale`.

By default the other available characters in the font, such as the Greek letters or the special braces or brackets, are not available in math. If you want those in a formula, you can load the package with the option `bbsymbols`. However, note that using that option means that the font is declared as a symbol font, and as discussed in Section 9.4.1 on page 1681, this means you are reducing your options to use other math fonts in your document. Therefore, do this only if you really intend to use any of the extra symbols.

	$0 \neq 1 \neq \mathbb{1}$	<code>\usepackage[bbsymbols,scale=0.9]{bboldx} \usepackage{amsmath}</code>
		<code>\$ \mathbbfbb{0} \neq \mathbb{1} \neq \mathbbfbb{1} \$</code>
		<code>\begin{align*} \mathbb{G} = \{ \llbracket \alpha, \beta, \gamma, \delta, \dots, \omega</code>
		<code>& \llbracket \alpha, \beta, \gamma, \delta, \dots, \omega</code>
		<code>& \llbracket \alpha, \beta, \gamma, \delta, \dots, \omega</code>
12-1-4	$\llbracket \alpha, \beta, \gamma, \delta, \dots, \omega \rrbracket \in \mathbb{G}$	<code>\llbracket \alpha, \beta, \gamma, \delta, \dots, \omega \rrbracket \in \mathbbfbb{G} \end{align*}</code>

A serified double stroke alphabet based on the Courier clone of URW in regular and bold is provided through the `ds serif` package by Michael Sharpe. It offers lower and uppercase Latin characters as well as digits and makes them available as `\mathbb`

*A double-stroke font
by Michael Sharpe*

and `\mathbfbb`. As usual, `scale` can be used to adjust the font size to other letters in the formulas.

$\mathbb{N} = \{0, 1, 2, 3, \dots\}$	<code>\usepackage{ds serif}</code>	
ABCDEFGHIJKLMNOPQRSTUVWXYZ	<code>\[\mathbb{N}=\{\mathbfbb{0},1,2,3,\ldots\} \]</code>	
abcdefghijklmnopqrstuvwxyz	<code>\[\mathbb{ \{ABCDEFGHIJKLMNOPQRSTUVWXYZ\} \]</code>	
	<code>\[\mathbfbb{abcdefghijklmnopqrstuvwxyz} \]</code>	12-1-5

*A double-stroke font
by Olaf Kummer*

The DS font designed by Olaf Kummer is a double stroke font that is based on the Computer Modern font shapes and thus works well in formulas done with Computer Modern or Latin Modern math fonts. Besides the usual uppercase alphabet, the font supports four additional characters: a variant form for the uppercase A (accessed by typing a lowercase a), lowercase h and k, and the digit 1. Trying anything else results in missing glyph warnings.

The package makes the alphabet available through the command `\mathds` and not through `\mathbb`. If you prefer the latter, you can alternatively set it up with the help of the `mathalpha` package or by using `\DeclareCommandCopy`.

ABCDEFGHIJKLMNOPQRSTUVWXYZ	<code>\usepackage{ds font}</code>	
A h k 1	<code>\[\mathds{ABCDEFGHIJKLMNOPQRSTUVWXYZ} \]</code>	
	<code>\[\mathds{a \quad h \quad k \quad 1} \]</code>	12-1-6

A nice feature of the package is that it alternatively offers you a matching Sans double stroke font, which is useful if your formulas are typeset with sans serif fonts, e.g., when making slides.

A B C D E F G H I J K L M N O P Q R S T U V W X Y Z	<code>\usepackage[sans]{ds font}</code>	
A h k 1	<code>\[\mathds{ABCDEFGHIJKLMNOPQRSTUVWXYZ} \]</code>	
	<code>\[\mathds{a \quad h \quad k \quad 1} \]</code>	12-1-7

*Setting up math
alphabets with* 
`\DeclareMathAlphabet`

As an example of small-scale changes to the mathematical typesetting, those who prefer a visually distinct blackboard bold alphabet can load a different one, for example, the one contained in the PX fonts. The necessary declaration is done with `\DeclareMathAlphabet`, which is described in Section 9.4.1. In the example we first load the `amsfonts` package and then overwrite its definition of `\mathbb`.

$\{n, m \in \mathbb{N} \mid \mathfrak{N}_{n,m}\}$	<code>\usepackage{ams fonts} \DeclareMathAlphabet\mathbb{U}{px-ds}{m}{n}</code>	
	<code>\$ \lbrace n,m \in \mathbb{N} \mid \mathfrak{N}_{n,m} \rbrace \$</code>	12-1-8

The previous example shows how to include arbitrary alphabets from your \LaTeX distribution as math alphabets, with the crucial part being the arguments of the `\DeclareMathAlphabet` declaration. Although getting these right may appear to be a tricky matter, it is not so difficult once you know where to look. Fonts suitable for inclusion need to have an `.fd` file of the form `\langle enc \rangle \langle name \rangle .fd`, where the `\langle name \rangle` is the font family name, often abbreviated — see the discussion on NFSS font family naming conventions on page 6. Chapter 10 covers more than one hundred high-quality font families and the necessary information to use them.

For example, Table 10.11 on page 22 shows the different Lucida fonts¹ including Lucida Handwriting, which has the name `hlcw` as documented there. Table 10.85 on page 100 exhibits the freely available Almendra family with the name `Almndr-OsF`. Both families are inspired by chancery handwriting. The tables also show which encodings and which shapes are supported. If you want to use a family not documented in this chapter, look into its `.fd` file to find the information for the remaining arguments for the `\DeclareMathAlphabet` declaration.

Both families are available in several encodings, but Lucida Handwriting exists only in series `m` and shape `it`, so there is no choice there. Almendra in contrast is offered in several shapes. In the example below we use this information to set up Lucida Handwriting as the `\mathcal` alphabet and the italic Almendra shape (which is fairly upright) as the `\mathscr` alphabet:

	<code>\DeclareMathAlphabet\mathcal{T1}{hlcw}{m}{it}</code>	
	<code>\DeclareMathAlphabet\mathscr{T1}{Almndr-OsF}{m}{it}</code>	
	<code>\[A_B \neq \mathscr{A}_\mathscr{B}</code>	
	<code>\neq \mathcal{A}_\mathcal{B}</code>	<code>\]</code>
12-1-9	$A_B \neq \mathscr{A}_\mathscr{B}$	$\mathcal{A}_\mathcal{B}$
	<code>\[\mathcal{A}\mathcal{B}\mathcal{C}\mathcal{D}\mathcal{E}\mathcal{F}\mathcal{G}\mathcal{H}\mathcal{I} \dots \mathcal{P}\mathcal{Q}\mathcal{R}\mathcal{S}\mathcal{T}\mathcal{U}\mathcal{V}\mathcal{W}\mathcal{X}\mathcal{Y}\mathcal{Z}</code>	<code>\[\mathcal{A}\mathcal{B}\mathcal{C}\mathcal{D}\mathcal{E}\mathcal{F}\mathcal{G}\mathcal{H}\mathcal{I} \dots \mathcal{P}\mathcal{Q}\mathcal{R}\mathcal{S}\mathcal{T}\mathcal{U}\mathcal{V}\mathcal{W}\mathcal{X}\mathcal{Y}\mathcal{Z}</code>

The above example clearly shows that you have to be careful which fonts you mix and match: the two alphabets used there show noticeable difference in the heights of the capitals. If this is the case, then using `\DeclareMathAlphabet` may not be a viable option because it does not offer you a way to customize the loading. For this you would need to alter the information in the `.fd` file and provide your own. While this is possible (see Section 9.8 on page 740), it is much simpler to use the `mathalpha` package if the font is supported by it, because that package allows you to load math alphabets scaled up or down as necessary; see Section 12.1.1 on the next page.

As mentioned, except for the Lucida and the Cambria fonts all font families documented in Chapter 10 are freely available, so you should be able to choose any of them and get it working without problems. Of course, in general the presence of an `.fd` file (such as `t1hlcw.fd`) on your system does not mean that you can use the font it describes successfully. Most modern \LaTeX installations contain such support files for various commercial font sets so that you can use these fonts the moment you buy them and add them to your system. Thus, the previous example will work for you only if you own the Lucida fonts.

In truth, you probably do not need to buy any fonts (though most are definitely worth the cost), because the freely available fonts already include a huge — and high-quality — choice as exhibited in Chapter 10. The `nfssfont.tex` or `unicodefont.tex` programs can provide valuable help in choosing a font, by producing glyph tables for the fonts available to your installation (see Sections 9.5.9 and 9.6.7).

As a final example for manual math alphabet setup we look at the RSFS script font by Ralph Smith, which was one of the first available alternatives to the calligraphic Computer Modern letters designed by Donald Knuth. Given that both alphabets are quite distinct, many people use the more formal RSFS script as `\mathscr` and retain

*Ralph Smith's
Formal Script
Symbol Font*

¹This is one of the two commercial font families covered in the book; all others are freely available.

a second calligraphic alphabet in `\mathcal` as shown in the example. There also exists a small `mathrsfs` package in most distributions, but it sets up the font as a symbol font and so wastes one of the precious sixteen math family slots. We therefore recommend declaring it as shown below (or by using the `mathalpha` package):

<i>A B C D E F G H I J K L M</i>	<code>\usepackage{amsmath}</code>	
<i>N O P Q R S T U V W X Y Z</i>	<code>\DeclareMathAlphabet\mathscr{U}{rsfs}{m}{n}</code>	
<i>A B C D E F G H I J K L M N O P Q R S T U V W X Y Z</i>	<code>\begin{multline*} \mathscr{A} \mathscr{B} \mathscr{C} \mathscr{D} \mathscr{E} \mathscr{F} \mathscr{G} \mathscr{H} \mathscr{I} \mathscr{J} \mathscr{K} \mathscr{L} \mathscr{M} \mathscr{N} \mathscr{O} \mathscr{P} \mathscr{Q} \mathscr{R} \mathscr{S} \mathscr{T} \mathscr{U} \mathscr{V} \mathscr{W} \mathscr{X} \mathscr{Y} \mathscr{Z} \end{multline*}</code>	
	<code>\mathcal{A} \mathcal{B} \mathcal{C} \mathcal{D} \mathcal{E} \mathcal{F} \mathcal{G} \mathcal{H} \mathcal{I} \mathcal{J} \mathcal{K} \mathcal{L} \mathcal{M} \mathcal{N} \mathcal{O} \mathcal{P} \mathcal{Q} \mathcal{R} \mathcal{S} \mathcal{T} \mathcal{U} \mathcal{V} \mathcal{W} \mathcal{X} \mathcal{Y} \mathcal{Z}</code>	12-1-10

If you prefer a more upright design, then you can try the `RSFSO` variant by Michael Sharpe shown below. It too can be set up using `mathalpha` if that is preferred.

<i>A B C D E F G H I J K L M</i>	<code>\usepackage{amsmath}</code>	
<i>N O P Q R S T U V W X Y Z</i>	<code>\DeclareMathAlphabet\mathscr{U}{rsfso}{m}{n}</code>	
	<code>\begin{multline*} \mathscr{A} \mathscr{B} \mathscr{C} \mathscr{D} \mathscr{E} \mathscr{F} \mathscr{G} \mathscr{H} \mathscr{I} \mathscr{J} \mathscr{K} \mathscr{L} \mathscr{M} \mathscr{N} \mathscr{O} \mathscr{P} \mathscr{Q} \mathscr{R} \mathscr{S} \mathscr{T} \mathscr{U} \mathscr{V} \mathscr{W} \mathscr{X} \mathscr{Y} \mathscr{Z} \end{multline*}</code>	
	<code>\mathcal{A} \mathcal{B} \mathcal{C} \mathcal{D} \mathcal{E} \mathcal{F} \mathcal{G} \mathcal{H} \mathcal{I} \mathcal{J} \mathcal{K} \mathcal{L} \mathcal{M} \mathcal{N} \mathcal{O} \mathcal{P} \mathcal{Q} \mathcal{R} \mathcal{S} \mathcal{T} \mathcal{U} \mathcal{V} \mathcal{W} \mathcal{X} \mathcal{Y} \mathcal{Z}</code>	12-1-11

12.1.1 `mathalpha` — Simplified setup for math alphabets

So far we have seen small packages for setting up additional math alphabets as well as the manual method through `\DeclareMathAlphabet`. In his `mathalpha` package, Michael Sharpe offers a much more convenient interface to this that allows you to set up `\mathcal`, `\mathscr`, `\mathbb`, and `\mathfrak` in one go by supplying suitable key/value pairs as package options. To give a practical example we assign different font families to the math alphabets by using the keys `cal`, `scr`, `bb`, and `frak` and as values the chosen fonts, e.g., `zapfc` stands for Hermann Zapf's Chancery italic script. Other font values are discussed below.

<i>A B C D E F G H I J K L M N O P ...</i>	<code>\usepackage[cal=zapfc,scr=boondoxo,bb=txof,frak=esstix]</code>	
<i>A B C D E F G H I J K L M N O P ...</i>	<code>{mathalpha}</code>	
<i>A B C D E F G H I J K L M N O P ...</i>	<code>\newcommand\sample[1]{\mathcal{A} \mathcal{B} \mathcal{C} \mathcal{D} \mathcal{E} \mathcal{F} \mathcal{G} \mathcal{H} \mathcal{I} \mathcal{J} \mathcal{K} \mathcal{L} \mathcal{M} \mathcal{N} \mathcal{O} \mathcal{P} \dots}</code>	
<i>A B C D E F G H I J K L M N O P ...</i>	<code>\sample\mathcal \sample\mathscr</code>	
<i>A B C D E F G H I J K L M N O P ...</i>	<code>\sample\mathbb \sample\mathfrak</code>	12-1-12

Some fonts, for example `dutchcal`, have bold variants. If that is the case, then those are made accessible through further math alphabets named `\mathbfc`, `\mathbfs`, `\mathbbf`, and `\mathfrakf` as shown below:

<i>A B C D E F G H I J K L M N O P ...</i>	<code>\usepackage[cal=dutchcal,frak=euler]{mathalpha}</code>	
<i>A B C D E F G H I J K L M N O P ...</i>	<code>\newcommand\sample[1]{\mathcal{A} \mathcal{B} \mathcal{C} \mathcal{D} \mathcal{E} \mathcal{F} \mathcal{G} \mathcal{H} \mathcal{I} \mathcal{J} \mathcal{K} \mathcal{L} \mathcal{M} \mathcal{N} \mathcal{O} \mathcal{P} \dots}</code>	
<i>A B C D E F G H I J K L M N O P ...</i>	<code>\sample\mathcal \sample\mathbfc</code>	
<i>A B C D E F G H I J K L M N O P ...</i>	<code>\sample\mathfrak \sample\mathfrakf</code>	12-1-13

If you want to use the bold variant as the default, you can use one or more of the options `bfbb`, `bfc`, `bff`, or `bfscr` to arrange for this.

We already mentioned that alphabets sometimes need slight adjustments in size to comfortably fit with the rest of the math formula. To help you with this task, the package offers four keys that allow you to scale the alphabets up or down. They are named `bbscaled`, `calscaled`, `frakscaled`, and `scrscaled`, and if given, they expect a numerical value, such as 0.95, to scale the respective alphabet down by 5%, etc.

The package knows about many font families that are useful candidates for math alphabets: several commercial fonts as well as many free ones. However, it is obviously impossible for the package to cover everything; e.g., if you want to use *Almendra* as we did in Example 12-1-9 on page 229, you have to use the method shown there, because *Almendra* is not in the list of supported font families. Once in a while Michael adds support for further math alphabets, and to give you a simple way to see what is currently available, there is the option `showoptions`. If you use it when loading the package, it replies by throwing an error message that lists all available option keys and their supported values; i.e., you get output like this:

```
Package mathalfa Error: Package Options:
```

```
bb=ams, lucida, mathpi, mma, mt, mth, pazo, fourier, esstix, boondox,
px, tx, txof, libus, ds serif, bboldxLight, bboldx, dsfont serif,
dsfont sans, stixtwo, stix

```

To help you with the selection, we show samples of different supported fonts sorted by type. The value to use is shown in the margin; if the font has a bold variant the indicator (*bold*) is added after the value. This means that `\mathbfcal`, `\mathbfscr`, `\mathbffrac`, or `\mathbfbb` is also set up when such a font is chosen as the value.

Selection of supported Calligraphic and Script math alphabets

We start with the calligraphic fonts that can be used with the keys `cal` or `scr`, grouped into “upright”, “oblique restrained”, and “oblique embellished”. Initially, the list of allowed alphabets for `cal` and `scr` differed, but as shown above, they now accept the same set of values. For details on which alphabets are supported, see the output of the `showoptions` option.

The value `euler` refers to the Euler Script fonts, which we have already seen in Example 12-1-2 on page 227; `txupr` is an upright script that is based on the TX fonts, and `boondoxupr` is based on the STIX font designs.

<code>euler</code>	<i>A B C D E F G H I J K L M N O P Q R S T U V W X Y Z</i>
<code>euler (bold)</code>	<i>A B C D E F G H I J K L M N O P Q R S T U V W X Y Z</i>
<code>txupr</code>	<i>A B C D E F G H I J K L M N O P Q R S T U V W X Y Z</i>
<code>boondoxupr</code>	<i>A B C D E F G H I J K L M N O P Q R S T U V W X Y Z</i>

In the second group we compare the slanted alphabets with relatively simple (restrained) glyph shapes. The value `cm` refers to the Computer Modern Calligraphic alphabet (which is the default for `\mathcal`), `lucida` refers to the Lucida calligraphic math alphabet (i.e., designed for use in math), `zapfc` is Hermann Zapf's chancery font (see Table 10.87 on page 103) but adjusted for math instead of text typesetting, and `pmtx` is the calligraphic math alphabet from the TX/PX fonts inspired by Palatino.

<code>cm</code>	<i>A B C D E F G H I J K L M N O P Q R S T U V W X Y Z</i>
<code>cm (bold)</code>	<i>A B C D E F G H I J K L M N O P Q R S T U V W X Y Z</i>
<code>lucida</code>	<i>A B C D E F G H I J K L M N O P Q R S T U V W X Y Z</i>
<code>lucida (bold)</code>	<i>A B C D E F G H I J K L M N O P Q R S T U V W X Y Z</i>
<code>zapfc</code>	<i>A B C D E F G H I J K L M N O P Q R S T U V W X Y Z</i>
<code>pmtx</code>	<i>A B C D E F G H I J K L M N O P Q R S T U V W X Y Z</i>
<code>pmtx (bold)</code>	<i>A B C D E F G H I J K L M N O P Q R S T U V W X Y Z</i>
<code>stixplain</code>	<i>A B C D E F G H I J K L M N O P Q R S T U V W X Y Z</i>
<code>stixplain (bold)</code>	<i>A B C D E F G H I J K L M N O P Q R S T U V W X Y Z</i>
<code>stixtwoplain</code>	<i>A B C D E F G H I J K L M N O P Q R S T U V W X Y Z</i>

The embellished scripts are much more expressive than the previous set. The value `dutchcal` refers to an adaptation by Michael Sharpe of a design from Elsevier Publishing later donated to the STIX project, `rsfs` is Ralph's Smith Formal Script as shown in Example 12-1-10 on page 230; `boondox` is the calligraphic math alphabet of the STIX fonts, slightly adjusted by Michael Sharpe; and the `kp` fonts represent the calligraphic alphabet from the Johannes Kepler fonts (a.k.a. KP fonts). There are also `rsfso` and `boondoxo`, both being less slanted variants of their originals. They have been also prepared by Michael Sharpe.

<code>dutchcal</code>	<i>A B C D E F G H I J K L M N O P Q R S T U V W X Y Z</i>
<code>dutchcal (bold)</code>	<i>A B C D E F G H I J K L M N O P Q R S T U V W X Y Z</i>

<i>A B C D E F G H I J K L M N O P Q R S T U V W X Y Z</i>	<i>rsfso</i>

<i>A B C D E F G H I J K L M N O P Q R S T U V W X Y Z</i>	<i>stixfancy (bold)</i>

Selection of supported Fraktur math alphabets

Most Fraktur alphabets follow a similar design, but with recognizable differences in several shapes. The only exception is the lucida blackletter alphabet, which offers various shapes that are noticeably different from historical models. *pmtx* and *euler* are designs by Hermann Zapf (1918–2015) (or rather inspired by in the case of *pmtx*) and *esstix* and *boondox* are adaptations of the Fraktur fonts from STIX, and one can easily see the close relationship.

<i>A B C D E F G H I J K L M N O P Q R S T U V W X Y Z</i>	<i>pmtx</i>
<i>A B C D E F G H I J K L M N O P Q R S T U V W X Y Z</i>	<i>pmtx (bold)</i>
<i>A B C D E F G H I J K L M N O P Q R S T U V W X Y Z</i>	<i>euler</i>
<i>A B C D E F G H I J K L M N O P Q R S T U V W X Y Z</i>	<i>euler (bold)</i>
<i>A B C D E F G H I J K L M N O P Q R S T U V W X Y Z</i>	<i>esstix</i>
<i>A B C D E F G H I J K L M N O P Q R S T U V W X Y Z</i>	<i>boondox</i>
<i>A B C D E F G H I J K L M N O P Q R S T U V W X Y Z</i>	<i>boondox (bold)</i>
<i>A B C D E F G H I J K L M N O P Q R S T U V W X Y Z</i>	<i>stixtwo</i>
<i>A B C D E F G H I J K L M N O P Q R S T U V W X Y Z</i>	<i>stixtwo (bold)</i>
<i>A B C D E F G H I J K L M N O P Q R S T U V W X Y Z</i>	<i>lucida</i>

Selection of supported Blackboard Bold math alphabets

Among the blackboard bold alphabets are two major styles: those that show hollowed-out shapes, i.e., where most parts of the glyphs show their contours, and the more

geometric shapes where the usual character shape is augmented by a single extra vertical or diagonal line (the Lucida design is somewhere in between the two).

Hollowed-out shapes are those from the AMS fonts referred to as `ams`; the open-faced design from the TX fonts is accessed with `txof`, and `lucida` represents the more sans serif open-faced design of the Lucida math fonts.

```
ams  A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
txof A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
txof (bold) A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
lucida A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
```

If you are looking for a more traditional¹ geometric-shaped blackboard bold typeface, then you have a choice between serifed designs, i.e., `pazo` from the Pazo Math fonts and `px` from the PX fonts, both of which are based on Palatino and nearly identical, and the `dsfontserif` math alphabet from the DS fonts.

```
pazo  A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
px    A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
px (bold) A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
dsfontserif A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
```

The DS fonts also offer a sans variant with `dsfontsans`. The other sans designs are nearly identical. Between `esstix` and `boondox` there are minor differences in stroke lengths of E and F and the `bbold` alphabet by Alan Jeffrey and its light and bold versions by Michael Sharpe have some stroke variations in some letters compared to the former two alphabets.

```
dsfontsans A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
esstix     A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
boondox    A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
bbold (light) A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
bbold      A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
bbold (bold) A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
```

The list of supported designs is larger than the number of examples shown above; not included are the commercial fonts (except for Lucida) and a few that are virtually identical to others. Furthermore, the list might grow over time; thus, for the full list, use the `showoptions` key or refer to the package documentation.

¹At least my math teachers used the approach of an extra stroke in this way on a blackboard.

12.2 Making it bold

For bold Latin letters only, you can use the command `\mathbf`; for everything else, there is the `bm` package. Although `amsmath` provides `\boldsymbol` and `\pmb`, the rules about when to use which command, and many of the restrictions on when they work, can now be avoided: just load the `bm` package and use `\bm` to make any formula as bold and beautiful as the available fonts allow.

12.2.1 `bm` — Making bold

The `bm` package by David Carlisle addresses the problem that it is rather difficult to bolden individual symbols in a math formula without altering the spacing or introducing other unwanted side effects.¹

The example below shows many ways to use the `\bm` and `\mathbf` commands and a strategy for defining shorthand names for frequently occurring bold symbols, using both standard L^AT_EX's `\newcommand` and `\bmdefine`, which is provided by `bm`. Note that `\mathbf{xy}` is not identical to `\bm{xy}`: the former produces bold roman “**xy**”, and the latter produces “***xy***” (i.e., bold math italic).

```
\usepackage{amsmath,amssymb,bm}
\newcommand\bfB{\mathbf{B}}      \newcommand\bfX{\mathbf{x}}
\bmdefine\bpi{\pi}              \bmdefine\binfty{\infty}
\section{The bold equivalence}

$$\sum_{j < B} \prod_{\lambda} : \bm{\sum_{x_j} \prod_{\lambda}}$$

\begin{gather}
B_{\infty} + \pi B_1 \sim \bfB_{\binfty} \bm{+} \bpi \bfB_{\bm{1}} \\
\bm{\sim B_{\infty} + \pi B_1} \\
B_{\binfty} + \bpi B_{\bm{1}} \bm{\in} \bm{\biggl\{ \frac{\partial \bfB}{\partial \bfX} : \frac{\partial \bfB}{\partial \bfX} \bm{\gtrsim} 1 \biggr\}} \\
\bm{\lnapprox} \bm{1} \bm{\biggr\rbrace}
\end{gather}
```

1 The bold equivalence $\sum_{j < B} \prod_{\lambda} : \sum_{x_j} \prod_{\lambda}$

$$B_{\infty} + \pi B_1 \sim \mathbf{B}_{\infty} + \pi \mathbf{B}_1 \sim B_{\infty} + \pi B_1 \quad (1)$$

$$B_{\infty} + \pi B_1 \in \left\{ (\mathbf{B}, \mathbf{x}) : \frac{\partial \mathbf{B}}{\partial \mathbf{x}} \gtrsim 1 \right\} \quad (2)$$

12-2-1

In the above example `bm` tries its best to fulfill the requests for bold versions of individual symbols and letters, but if you look closely, you will see that the results are not always optimal. For example, \sum , \prod , and \gtrsim are all made bold by the use of a technique known as *poor man's bold*, in which the symbol is overprinted three times with slight offsets. Also, the $\{$ is not made bold in any way. Such deficiencies are

 *bm cannot do miracles if symbols are not available in a bold variant*

¹However, `bm` is unfortunately not usable with Unicode engines — this might change though.

This situation can be improved by use of the `newtxmath` package (as in Example 12-2-2) or use of another font set with full bold variants, such as the `newpxmath` shown here:

12-2-4

$$\left\{ \left\{ \left\{ \left\{ \left\{ Q \right\} \right\} \right\} \right\} \right\}$$

```
\usepackage{newpxmath,bm}
$ \bm{\Biggl\lbrace\biggl\lbrace\Bigl\lbrace\bigl\lbrace \lbrace
\mathcal{Q}}
\rangle \bigr\rangle\Bigr\rangle\biggr\rangle\Biggr\rangle\Bigr\rangle$
```

Normally, `\bm` requires that if a command that itself takes arguments is within its argument, then that command must be fully included (i.e., both the command and its arguments must appear) in the argument of `\bm`; as a result, all parts of the typeset material are typeset in bold. If you really need the output of a command with arguments to be only partially bold, then you have to work harder. You should place the symbol(s) that should not be bold in an `\mbox` and explicitly reset the math version within the box contents using `\unboldmath`. T_EX considers an `\mbox` to be a symbol of class Ordinary (see Section 11.8.1); hence, to get the spacing right, you may have to surround it by a `\mathbin`, `\mathrel`, or `\mathop`.

12-2-5

$$\sqrt[2]{x \times \alpha} \text{ but } \sqrt[2]{x \times \alpha}$$

or the similar $\sqrt{x \times \alpha}$

```
\usepackage{amsmath,bm}
$ \bm{\sqrt[2]{x \times \alpha}} $ but
$ \bm{\sqrt[2]{x \mathbin{\mbox{\unboldmath$\times$}}
\alpha}}} $
or the similar
$ \bm{\sqrtsign}{\bm{x} \times \bm{\alpha}} $
```

Fortunately, such gymnastics are seldom needed. In most cases involving commands with arguments, only parts of the arguments need to be made bold, which can be achieved by using `\bm` inside those arguments. As with `\sqrtsign` in the example above, for the common case of bold accents `\bm` is specially programmed to allow the accent's argument to be outside its own argument. However, if you need such accents regularly, it is wise to define your own abbreviation using `\bmdefine`, as in the next example:

12-2-6

$$\hat{a} \neq \hat{\hat{a}} \neq \hat{a} = \hat{a} \neq \hat{\hat{a}}$$

```
\usepackage{bm} \bmdefine\bhat{\hat}
$ \hat a \neq \bm{\hat a} \neq \bm\hat a = \bhat a
\neq \bm\widehat a $
```

This example also shows that the variable-width accents (e.g., `\widehat`) share a deficiency with the delimiters: in the Computer Modern math setup they come from a font for which no bold variant is available.

Although `\bmdefine\blambda{\lambda}` appears to be simply a shorthand for `\newcommand\blambda{\bm{\lambda}}`, in fact almost the opposite is true: `\bm` defines a new hidden temporary command using `\bmdefine` and then immediately uses this temporary command to produce the bold symbol. In other words,

*Speeding up the
processing*

`\bmdefine` does all the hard work! If you frequently use, for example, something that is defined via `\bm{\alpha}`, then a new `\bmdefine` is executed at every use. If you set things up by doing `\bmdefine\balpha{\alpha}`, then `\bmdefine` does its time-consuming work only once, however many times `\balpha` is used.

Dealing with strange errors

The `bm` package tries very hard to produce the correct spacing between symbols (both inside and outside the argument of `\bm`). For this effort to work, `\bm` has to “investigate” the definitions of the commands in its argument to determine the correct mathematical class to which each of the resulting symbols belongs (see Section 11.8.1 on page 209). It is possible that some complicated constructions could confuse this investigation. If this happens, then \LaTeX will almost certainly stop with a strange error. Ideally, this problem should not arise with constructs from standard \LaTeX or `amsmath`, but proper parsing in \TeX is extremely difficult, and the odd overlooked case might still be present.¹

If some command does produce an error when used inside `\bm`, you can always surround it *and all its arguments* with an extra level of braces — for example, writing `\bm{...{\cmd}...}` rather than simply `\bm{...{\cmd}...}`. The `\bm` command does not attempt to parse material surrounded by braces but uses the `\boldmath` version to typeset the whole of the formula within the braces. The resulting bold subformula is then inserted as if it were a “symbol” of class Ordinary. Thus, to obtain the right spacing around it, you may have to explicitly set its class; for instance, for a relation you would use `\bm{...{\mathrel}{\cmd}...}` (see Section 11.8.1 on page 209).

12.3 Traditional math font setup through packages

Implementing a setup for math in \LaTeX is a rather complicated undertaking and not something you do in a preamble of your document. There you might add a few declarations for math alphabets with `\DeclareMathAlphabet` or through the packages discussed in Section 12.1 or define your own notations as we have done in several examples throughout the book.

However, if you want to replace all glyphs used in formulas with new ones that have a different design, you typically simply call one or more packages that do the hard work for you behind the scenes. In this section we discuss a number of them. As mentioned earlier, most of them can be used with every \TeX engine even if they are based on 8-bit fonts.² Setting up math using Unicode fonts (and thus usable only with Unicode engines) is the subject of Section 12.4.

12.3.1 cfonts — The Concrete fonts for text and math

Starting from the work done for the EC fonts, it was relatively easy to create Concrete Roman fonts in T1 and TS1 encodings (original work by Frank Mittelbach; current version by Walter Schmidt (1960–2021)). Ulrik Vieth used the construction method

¹For instance, the author got trapped when writing this section by the fact that `\bm` was trying to process the argument of `\hspace` instead of producing the desired space (now fixed).

²As long as they do not also set up text fonts, that is.

outlined by Knuth [94] to develop a companion set of Concrete Math fonts including the full range of AMS symbols (as provided by the `amssymb` or `amsfonts` package).

The first package that provided access to these font families for normal text was `beton` (by Frank Jensen). A more recent development that also provides the use of Concrete fonts for math and supports the T1 and TS1 encodings is the `ccfonts` package by Walter Schmidt; see page 65 for details.

Because the Concrete fonts have no boldface series, the `ccfonts` package offers the option `boldsans` to use the semibold series of the Computer Modern Sans fonts as a replacement. As a result, without any further adjustments, headings in standard classes are typeset using this font series. A larger sample page is shown in Figure 12.39 on page 288.

1 Testing headings

An example showing a trigonometric function:

$$\sin \frac{\alpha}{2} = \pm \sqrt{\frac{1 - \cos \alpha}{2}}$$

The script looks like this: ABC .

12-3-1

Text symbols: \$ € ★ ∞ † ...

```
\usepackage[boldsans]{ccfonts}
```

```
\section{Testing headings}
```

An example showing a trigonometric function:

$$\sin \frac{\alpha}{2} = \pm \sqrt{\frac{1 - \cos \alpha}{2}}$$

The script looks like this: `\mathcal{ABC}`. `\`

Text symbols: \textdollaroldstyle\ \texteuro\

\textborn\ \textmarried\ \textdied\ \ldots

Because the Concrete fonts are of considerably heavier weight than, say, Computer Modern, it is advisable to use them with a larger leading than most document classes provide by default. For this reason the package automatically enlarges the leading to 10/13 and similar ratios for other document sizes. If this adjustment is undesirable for some reason, it can be canceled with the option `standard-baselineskips`.

The feature provided by the `exscale` package is available as the package option `exscale`; see Section 9.5.7 on page 704 for details. The `exscale` package itself cannot be used because it is set up to work with only Computer Modern math fonts.

If the `amssymb` or `amsfonts` package is loaded, the `ccfonts` package automatically arranges to use the Concrete variants of the AMS symbol fonts.

Finally, the package offers the option `slantedGreek` to make uppercase Greek letters slanted instead of being upright (default). The two extra commands `\upDelta` and `\upOmega` always typeset an upright Δ and Ω , respectively.

12.3.2 cmbright—The Computer Modern Bright fonts

Another font family whose design is based on the METAFONT sources of the CM fonts are the Computer Modern Bright (CM Bright) fonts by Walter Schmidt (1960–2021), shown in Table 10.3 on page 12. This family of sans serif fonts is designed to serve as a legible body font. It comes with matching typewriter and math fonts, including the American Mathematical Society symbols.

Loading the `cmbright` package in the preamble ensures that these families are selected throughout the document. It is recommended that you combine this package with `fontenc`, as shown in the next example, to achieve proper hyphenation with languages other than English. All CM Bright fonts have fully implemented T1 and TS1 encoding support.

1 A CM Bright document

The CM Bright family contains typewriter fonts and matching fonts for math formulas, e.g.,

$$\sum_{0 \leq k < n} k = \frac{n(n-1)}{2}$$

```
\usepackage[T1]{fontenc}
\usepackage{cmbright}
\section{A CM Bright document}
The CM Bright family contains
\texttt{typewriter} fonts and matching fonts
for math formulas, e.g.,
\[ \sum_{0 \leq k < n} k = \frac{n(n-1)}{2} \]
```

12-3-2

By default, the package selects a slightly larger leading than the default classes to account for the use of sans serif fonts; this can be canceled by specifying the package option `standard-baselineskips`. Also in other respects, this package works similarly to other works by Walter: the option `slantedGreek` produces slanted uppercase Greek letters, with `\upDelta` and `\upOmega` typesetting an upright Δ and Ω , respectively. When the `amssymb` or `amsfonts` package is loaded, the `cmbright` package automatically arranges to use the CM Bright variants of the AMS symbol fonts.

The METAFONT implementation of the fonts is freely available from CTAN archives; Type 1 format versions have been commercially sold by MicroPress. In 2002, a freely available Type 1 (although without manual hinting) was made available by Harald Harders under the name `hfbright`. Moreover, as mentioned in Section 9.5.1, the freely available CM-Super Type 1 fonts also cover parts of the CM Bright fonts.

12.3.3 euler, eulervm — Accessing Zapf's Euler fonts

As mentioned earlier, Hermann Zapf (1918–2015) designed a beautiful set of fonts for typesetting mathematics — upright characters with a handwritten flavor — named after the famous mathematician Leonhard Euler [100]. These fonts can be accessed as (math) alphabets of their own, or you can generally modify the math font setup, thus making \LaTeX use Euler math fonts (rather than Computer Modern) by default.

The Euler fonts contain three math alphabets: `SCRIPT`, Euler Fraktur, and Euler Roman.¹ The script and the fraktur alphabets can be easily set up with the `mathalpha` package, but for historical reasons there also exist individual packages to set them up. For the script alphabet you can alternatively use the `eucal` package, which makes this math alphabet available under the name `\mathcal`. If the package is loaded with the `mathscr` option, the alphabet becomes available through the command `\mathscr`, with `\mathcal` retaining its original definition. The package for Euler Fraktur is `eufrak`, which defines the math alphabet `\mathfrak`. There is no particular package to access the Euler Roman alphabet separately.

¹None of these alphabets is suitable for typesetting text because the individual glyphs have side-bearings specially tailored for use in math formulas.

The next example shows Computer Modern Calligraphic, Euler Script, and Euler Fraktur side by side. We use the `mathalpha` approach but also show the equivalent older way using the packages `eucal` and `eufrak`:

12-3-3

$$\mathcal{A} \neq \sum_{k < n} \mathcal{A}_k \neq \mathfrak{A}$$

```
%\usepackage[mathscr]{eucal} \usepackage{eufrak} % old way
\usepackage[scr=euler,frak=euler]{mathalpha}
\[ \mathcal{A} \neq \sum_{k < n} \mathscr{A}_k \neq \mathfrak{A} \]
```

Unfortunately, the Euler fonts use font encodings that differ from all other encoding schemes for mathematics. For this reason, the fonts are all assigned the encoding U (unknown) in NFSS classification.

These nonstandard encodings make it difficult to simply substitute the Euler alphabets and symbols for the default CM math fonts. Yet the `euler` package, written by Frank Jensen, went exactly this way, redeclaring most of \LaTeX 's math font setup. In conjunction with the package `beton`, which sets up Concrete as the default text font family, it simulates the typography of Knuth's book *Concrete Mathematics* [58], as shown below:

Concrete Roman blends well with Euler Math,
as can be seen with

12-3-4

$$\sum_{0 \leq k < n} k = \frac{n(n-1)}{2}$$

```
\usepackage{beton,euler}
Concrete Roman blends well with Euler Math,
as can be seen with
\[ \sum_{0 \leq k < n} k = \frac{n(n-1)}{2} \]
```

One of the problems with extensive reencoding in macro packages, as done by the `euler` package, is that it is likely to break other packages that assume certain symbols in slot positions, as defined by the established standard font encodings. The `eulervm` package developed by Walter Schmidt (1960–2021) attempts to avoid this problem by providing reencoded virtual fonts that follow as much as possible the standard math encodings OML, OMS, and OMX.

The `eulervm` package sets up a `\mathnormal` alphabet, which is based mainly on Euler Roman, and a `\mathcal` alphabet, which is based on Euler Script. It does not provide immediate support for the Euler Fraktur alphabet — to access this math alphabet one needs to additionally load the `eufrak` or `mathalpha` package. Also, the math symbols are taken from the Euler fonts, with a few exceptions coming from the Computer Modern math fonts. Compare the next example to Example 12-3-3 and you see that `\mathcal` has changed and that `\sum` and the indices are different, because they are now taken from the Euler fonts.

12-3-5

$$\mathcal{A} \neq \sum_{k < n} \mathcal{A}_k \neq \mathfrak{A}$$

```
\usepackage{eulervm,eufrak}
\[ \mathcal{A} \neq \sum_{k < n} \mathcal{A}_k \neq \mathfrak{A} \]
```

In typical font setups the same digits are used in text and math formulas. The Euler fonts contain a set of digits that have a distinctive look and thus make digits in text and math look noticeably different.

Virtual Euler fonts

By default, the digits of the main document font are used in formulas as well. To switch to the digits from Euler Roman, one has to explicitly request them by specifying the option `euler-digits`. It then becomes very important to distinguish between a number in a mathematical or a textual context. For example, one must watch out for omitted \$ signs, as in the first line of the next example:

	<code>\usepackage{ccfonts}</code>		
	<code>\usepackage[euler-digits]{eulervm}</code>		
The value can be 1, 2, or -1 (wrong!)	The value can be 1, 2, or \$-1\$ (wrong!)\par		
The value can be 1, 2, or -1 (right!)	The value can be \$1\$, \$2\$, or \$-1\$ (right!)		12-3-6

A full sample page with this setup is shown in Figure 12.40 on page 289.

The option `small` causes `eulervm` to load all Euler fonts at 95% of their normal size, thereby enabling them to blend better with some document fonts (e.g., Adobe Minion). This option also affects the Euler Fraktur fonts if they are loaded with `eufrak` and the AMS symbol fonts.

The functionality provided by the `exscale` package is automatically available. See Section 9.5.7 on page 704 for details.

Some peculiarities of the Euler fonts

Neither the standard `\hbar` command nor `\hslash` (from the `amssymb` package) is really usable with the Euler fonts if it is used without modification (i.e., with `euler`), because `\hslash` uses a Computer Modern style “h” and `\hbar` gets the slash in a strange position.

This issue restricts the usage of the `euler` package somewhat for physics and related fields. The `eulervm` package resolves this problem (partially) by providing a properly slashed “h” glyph built using the possibilities offered by the virtual font mechanism ([93] explains the concepts). It does, however, provide only a slashed version (`\hslash`); if `\hbar` is used, a warning is issued, and the slashed glyph is used nevertheless.

<code>\usepackage{amssymb,euler}</code>	<code>\usepackage{eulervm}</code>
<code>\[\hslash \neq \hbar \]</code>	<code>\[\hslash \neq \hbar \]</code>
$\hbar \neq \hbar$	$\hbar \neq \hbar$
12-3-7	12-3-8

Normally, the math accent `\hat` is taken from the main document font, which might not be a good choice when text and math fonts are noticeably different. With the option `euler-hat-accent`, an alternative version from the Euler fonts is used instead. In the example we mimic that option and define the alternate accent under the name `\varhat` manually to enable comparison of the two (neither looks really perfect).

$\hat{x} \neq \hat{x} \text{ and } \hat{K} \neq \hat{K}$	<code>\usepackage{tgpagella,eulervm,eufrak}</code>
	<code>\DeclareMathAccent\varhat{\mathalpha}{symbols}{222}</code>
	<code>\Large \$ \hat{x} \neq \varhat{x} \$ and</code>
	<code>\$ \hat{\mathfrak{K}} \neq \varhat{\mathfrak{K}} \$</code>
	12-3-9

If `\mathbf` is used in an `eulervm` setup, it uses the bold text font, e.g., Concrete Bold in the next example (as the `ccfonts` package is used for text). To get bold Euler letters instead, you can use `\mathbold` provided by `eulervm` for this purpose.

12-3-10

Compare: $a + b \neq a + b \neq \mathbf{a} + \mathbf{b}$

```
\usepackage{ccfonts,eulervm}
```

```
Compare: $ a + b \neq \mathbf{a} + \mathbf{b}
\neq \mathbold{a} + \mathbold{b}$
```

Because `eulervm` defines the math alphabets (`\mathbf`, `\mathsf`, etc.) by evaluating the document's default information current at the time of loading, it is usually best to load the package after all the document fonts have been defined. In the previous and the next examples the loading order is in fact absolutely essential because the `ccfonts` package also tries to set up the math fonts, and thus the one that comes last wins.

In the book *Concrete Mathematics* [58], where Euler and Concrete fonts were first used together, one can see that slanted \leq and \geq signs were once part of the Euler Math fonts. Somewhere along the way these two symbols got lost, though traces of their existence can be found in [94] and in macros that Donald Knuth developed for producing the book. With the help of the virtual font mechanism, Walter Schmidt brought them back in the `eulervm` package; compare the next example to Example 12-3-4 on page 241, which shows the straight \leq sign.

Concrete Roman blends well with Euler Math, as can be seen with

12-3-11

$$\sum_{0 \leq k < n} k = \frac{n(n-1)}{2}$$

```
\usepackage{ccfonts,amssymb}
```

```
\usepackage[euler-digits]{eulervm}
```

Concrete Roman blends well with Euler Math, as can be seen with

```
\[ \sum_{0 \leq k < n} k = \frac{n(n-1)}{2} \]
```

12.3.4 newtxmath — A Swiss¹ knife for math font support

In 2000, Young Ryu released a set of virtual fonts together with accompanying Type 1 fonts to provide math support for documents using Times Roman as the document font. \LaTeX support was implemented through the package `txfonts`.

This implementation was fairly comprehensive in offering a large glyph set including all symbols from the American Mathematical Society fonts, but unfortunately it had some serious problems in that the glyph side-bearings in math were extremely tight, up to the point that characters actually touched if used in subscripts or superscripts. Compare the next two examples: the first is using the original TX fonts, while the second is using similar fonts prepared by Michael Sharpe.

A problematic example:

12-3-12

$$t[u_1, \dots, u_n] = \sum_{k=1}^n \binom{n-1}{k-1} (1-t)^{n-k} t^{k-1} u_k$$

```
\usepackage{amsmath,txfonts}
```

A problematic example:

```
\[ t[u_1, \dots, u_n] = \sum_{k=1}^n
\binom{n-1}{k-1} (1-t)^{n-k} t^{k-1} u_k \]
```

¹Or rather an Australian/California knife.

In fact, you can have both types in a single document by appending `up` or `sl` to the normal command names; which you need depends on your chosen default.

12-3-15

```

\usepackage{newtxmath}

\[ \intsl \iintup \iiintsl \iiiiiintup \enspace
\ointsl \oiintup \oiintsl \enspace
\varointclockwiseup \ointctrlockwisesl\enspace
\!fintup \sumintsl \saintup \! ]

```

The full set of the integral commands is also available as tiny symbols by prepending `small` to the names for upright and sloped integrals, e.g., `\smalliintsl`. These small versions may help in inline formulas when it is important to keep line registration and not open up the line with large symbols. The example below has the same input as Example 12-3-14, but with `small` prefixed to all command names, and the second set by additionally appending `sl`:

12-3-16

[illegible]

With the option `smallerops` you can reduce the size of all operators that can take `\limits`, e.g., those from Table 11.27 on page 222, about 20%. Integrals are not affected by this option.

The package also defines a few additional commands for use in math: `\smallsum`, `\smallprod`, and `\smallcoprod` are small versions of the operators and may sometimes be useful (for comparison, the normal size in running text is shown as well). There are also a number of “wide accents” that span the whole of their argument. They are shown in the display formulas of the example.

12-3-17

	<code>\usepackage{newtxtext,newtxmath}</code>
In running text: $\sum \sum_{i=1}^n \prod \prod_x^y \prod_z!$	<code>In running text: \$ \sum \smallsum_{i=1}^n \prod</code>
	<code>\smallprod_x^y \smallcoprod\limits_z \$!</code>
	<code>\[\overgroup{AB} \enspace \overgrouppra{CDEF} \enspace</code>
	<code>\overgrouppla{\ldots LMN\ldots} \enspace \widering{XYZ}</code>
$\overrightarrow{AB} \overrightarrow{CDEF} \overleftarrow{\dots LMN \dots} \overleftrightarrow{\overset{\circ}{XYZ}}$	<code>\]</code>
	<code>\[\undergroup{abc} \enspace \undergrouppra{de} \enspace</code>
$\underbrace{abc}_{de} \overleftrightarrow{\dots xyz}$	<code>\undergrouppla{\ldots xyz}</code>
	<code>\]</code>

It is customary in Anglo-American mathematical typesetting to use upright Greek uppercase letters and italic Greek lowercase together with all Latin characters in italics. ISO also suggests using slanted uppercase Greek. This can be controlled through the options `uprightGreek` (default) and `slantedGreek`. In any case all commands to access Greek letters (upper or lowercase) have a variant to explicitly access the upright form by prepending `up` to the command name, e.g., `\upDelta`, `\upOmega`, `\upalpha`, `\upbeta`, etc.

With the option `frenchmath` you set the default style in math mode for rendering uppercase Latin and all Greek letters to upright. Latin lowercase remains italic. You can still get the italic uppercase Latin glyphs by using `\mathnormal`.

```
\usepackage{newtxtext}
\usepackage{newtxmath}
\[ \mathrm{A} = \alpha + \beta
    < A_k \quad \backslash]
```

$$A = \alpha + \beta < A_k$$

12-3-18

```
\usepackage{newtxtext}
\usepackage[frenchmath]{newtxmath}
\[ A = \alpha + \beta
    < \mathnormal{A}_k \quad \backslash]
```

$$A = \alpha + \beta < A_k$$

12-3-19

The math italic *v* and the Greek ν are often fairly similar as shown in Example 12-3-20. For that reason the `newtxmath` package offers the option `varvw` to give both *v* and *w* a different shape, or the option `varg` that changes the shapes of *v*, *w*, *g*, and *y*. If you compare the two example, you can observe the differences. Unfortunately, the options make *w* now look closer to ω , so you have to pick and choose what works better for you.

```
\usepackage{newtxmath}
\[ v w \neq \nu \omega \quad \backslash]
```

$$v w \neq \nu \omega \quad (gy)$$

12-3-20

```
\usepackage[varg]{newtxmath}
\[ v w \neq \nu \omega \quad \backslash]
```

$$vw \neq \nu \omega \quad (gy)$$

12-3-21

With many heavily sloped math fonts there is a problem that the side-bearings of individual characters would need to change based on their usage, e.g., whether they appear as a variable in a formula or as a subscript character. This is not automatically possible for \TeX when sticking glyphs together, and the package attempts to solve this by some clever programming. To enable it, specify the option `subscriptcorrection`. If activated, an external file (default `newtx-subs.tex`) is read that specifies corrective actions for individual characters that are carried out whenever the glyph appears as the first character in a subscript (and only there). Compare the subscript placements in the next two examples:

```
\usepackage{newtxmath}
\[ xjfA \to x_j \neq y_f
    \neq z_A \quad \backslash]
```

$$xjfA \rightarrow x_j \neq y_f \neq z_A$$

12-3-22

```
\usepackage[subscriptcorrection]{newtxmath}
\[ xjfA \to x_j \neq y_f
    \neq z_A \quad \backslash]
```

$$xjfA \rightarrow x_j \neq y_f \neq z_A$$

12-3-23

Which characters are affected depend on the math fonts used (as we see below, you are not confined to Times), and it is customizable. How to do this is explained in the package documentation in case you feel you need to make further adjustments.

The original TX fonts offered two blackboard bold alphabets; the `newtxmath` packages adds yet another one (taking it from the STIX2 fonts). The alphabets are

available through `\mathbb`, `\vmathbb`, and `\vvarmathbb`. Given that you probably want only one within your document, you can make a selection via an option (`varbb` or `vvarbb`), in which case `\mathbb` is made equal to one of the other ones.

```
\usepackage{newtxtext}
\usepackage{newtxmath}
\[ \mathbb{AN} \text{ \textrm{\ (default)}}
  < \vmathbb{AN} < \vvarmathbb{AN} \]
```

12-3-24

$$\mathbb{AN} \text{ (default)} < \mathbb{AN} < \mathbb{AN}$$

```
\usepackage{newtxtext}
\usepackage[vvarbb]{newtxmath}
\[ \mathbb{AN} \text{ \textrm{\ (default)}}
  < \vmathbb{AN} < \vvarmathbb{AN} \]
```

12-3-25

$$\mathbb{AN} \text{ (default)} < \mathbb{AN} < \mathbb{AN}$$

A sample page using Times for text and math by loading the packages `newtxtext` and `newtxmath` is shown in Figure 12.27 on page 280.

Support for other math font families

Michael's package started out as a reimplementaion for the TX fonts, but over time support for more and more math font families got added. They can be accessed by adding an appropriate option when loading the package. The options change the math italics and bold math italics being loaded. If the new base family offers Greek glyphs (i.e., Cochineal, EB Garamond, Garamondx, Libertine, Minion, STIX 2, or XCharter), then these are used as well.

The other symbols remain the same, which is a compromise that is not necessarily perfect with all combinations compared to a design that was made to go together from the outset.

When one of these font options is selected, the options `varg` and `varvw` are both ignored (if given). Instead, there are a few extra options to cater for peculiarities of some of the font families, as explained below:

baskervaldx This loads math italics based on the glyphs from Baskervaldx; see Figure 12.15 on page 272 for a sample page. In Figure 12.16 there is also an example of Baskervaldx text combined with Times math.

baskerville or **baskervillef** This provides math italics based on BaskervilleF instead. An example is given in Figure 12.14 on page 271; compare it with Figure 12.15.

charter or **xcharter** In this case the math italics are based on the XCharter design. When this option is chosen, you can also use `alty` to get an alternative glyph for “y” and `noxchw` to have the original “v” and “w” from Charter italics. This makes them harder to distinguish from `\nu`, but that is a problem only if you use that Greek character. A sample page is shown in Figure 12.19 on page 275.

cochineal Figure 12.2 on page 263 shows the usage. With this option the italics from Cochineal are used as the basis for the math italics. It can be combined with the options `cochf` and `cochrho` to use a longer italic “f” and `\rho`, respectively.

ebgaramond Use math italics based on EB Garamond; see Figure 12.3 on page 264 for an example.

garamondx This uses Garamondx instead of EB Garamond as math italics. There is also an example page showing the OpenType font version. Compare Figures 12.3 to 12.5 on pages 264–265.

libertine This option uses math italics based on Libertine fonts. With the option **libaltvw** you can alter the look of “v” and “w”, and with **liby** that of “y” of the family. Figure 12.22 on page 277 shows an example. Compare this with Figure 12.23, which exhibits the Libertinus math fonts that are available only for Unicode engines.

minion This option bases the math italics on the commercial MinionPro fonts, which requires that you own a recent version of this family, and it requires manual installation because some components are not part of the \TeX Live distribution.

nc **or** **ncf** Both options use math italics based on New Century Schoolbook, the difference between the two options is that the **ncf** option uses Greek math from the Fourier fonts, while **nc** retains the glyphs from the TX fonts. An example is given in Figure 12.20 on page 276.

noto **or** **notosans** Use Noto Serif or Noto Sans as the basis for the math italics. If you also want to use the Noto fonts as your text fonts, then it is better to use the **notomath** described in Section 12.3.7 on page 252.

stix2 This option bases the math italics on the STIX 2 fonts. An example is given in Figure 12.30 on page 282. Compare this to Figure 12.31, which shows the OpenType STIX 2 fonts, and to Figure 12.29 (based on OpenType STIX 1), both usable only in Unicode \TeX engines.

utopia **or** **erewhon** The Utopia clone Erewhon is used as the basis for the math italics; an example page is shown in Figure 12.32 on page 283.

There are a few more options related to reducing the number of allocated math alphabets. However, with the more recent addition of **localmathalphabets** to the \LaTeX kernel, this is less of an issue. See Section 9.4.1 on page 681 for details.

12.3.5 newpxmath — Using the PX fonts for math

Besides support for Times in math, Young Ryu also developed a set of math fonts to work together with Palatino-like font families. These PX fonts were based on a Palatino Italic clone, together with all necessary symbols to cover all of the standard \LaTeX and **amsmath** symbols. Unfortunately, just as with his TX fonts the PX fonts have metrics that are overly tight.

For this reason Michael Sharpe produced a new version, made a few glyph additions, and completely reworked the metrics. His fonts (New PX) are made available through the `newpxmath` package. Below are both fonts set side by side for comparison:

`\usepackage{amsmath,pxfonts}`

A problematic example:

`\[t[u_1, \dots, u_n] = \sum_{k=1}^n \binom{n-1}{k-1} (1-t)^{n-k} t^{k-1} u_k \]`

A problematic example:

$$t[u_1, \dots, u_n] = \sum_{k=1}^n \binom{n-1}{k-1} (1-t)^{n-k} t^{k-1} u_k$$

12-3-26

`\usepackage{amsmath,newpxtext,newpxmath}`

A better result:

`\[t[u_1, \dots, u_n] = \sum_{k=1}^n \binom{n-1}{k-1} (1-t)^{n-k} t^{k-1} u_k \]`

A better result:

$$t[u_1, \dots, u_n] = \sum_{k=1}^n \binom{n-1}{k-1} (1-t)^{n-k} t^{k-1} u_k$$

12-3-27

Michael's package alters only the math setup, so you are free to combine it with any text font to which you think it fits with. Above we have combined it with his companion package for text, called `newpxtext`. This uses an augmented version of T_EX Gyre Pagella (Palatino clone) with superior figures and an additional set of larger small capitals added. You can activate them in your document by adding the option `largesc`. The package also sets up T_EX Gyre Heros (Helvetica clone) appropriately scaled as the sans serif family; this can be prevented through the option `nohelv`. Figure 12.10 on page 269 shows the combination of `newpxtext` and `newpxmath` on a sample page.

Most of the general functionality seen with the `newtxmath` package is also available with `newpxmath`, so we rehash it here only with a few examples. There is the same extended set of integrals available both in slanted form (default) or upright when using the option `upint`. You can explicitly select either form by appending up or sl to the command names.

$\int \iint \iiint \int \oint \oint \oint \oint \oint \oint \oint \oint$
 $\int \iint \iiint \int \oint \dots \oint \oint$

12-3-28

`\usepackage[upint]{newpxmath}`

`\[\int \iint \iiint \iiint \oint \oint \oint \oint \oint \oint \oint \oint`
`\varointclockwise \ointctrclockwise \fint \sumint \sqint \]`
`\[\intsl \iintup \iiintsl \iiintup`
`\ointsl \ointup \ldots \sumintsl \sqintup \]`

As with `newtxmath` the package supports the full set of integrals upright and slanted in tiny size by prepending `small` to the integral command name.

$\int \iint \iiint \int \oint \oint \oint \oint \oint \oint \oint \oint$ $\int \iint \iiint \int \oint \oint \oint \oint \oint \oint \oint \oint$

12-3-29

The option `smallerops` forces all big operators to render about 20% smaller with the result that many display formulas occupy noticeably less vertical space.

Also supported are additional small operators and wide accents as exhibited here:

In running text: $\sum \sum_{i=1}^n \prod \prod_x^y \prod_z$	<code>\usepackage{newpxtext,newpxmath}</code>	
	In running text: $\sum \sum_{i=1}^n \prod \prod_x^y \prod_z$	<code>\sum \smallsum_{i=1}^n \prod \smallprod_x^y \smallcoprod \limits_z</code>
$\overline{AB} \overrightarrow{CDEF} \overleftarrow{LMN} \overline{\overline{XYZ}}$	$\overline{AB} \overrightarrow{CDEF} \overleftarrow{LMN} \overline{\overline{XYZ}}$	<code>\[\overgroup{AB} \enspace \overgrouppra{CDEF} \enspace \overgrouppla{\ldots LMN\ldots} \enspace \widening{XYZ} \]</code>
$\underline{abc} \underline{\underline{de}} \underline{\underline{\underline{xyz}}}$	$\underline{abc} \underline{\underline{de}} \underline{\underline{\underline{xyz}}}$	<code>\[\undergroup{abc} \enspace \undergrouppra{de} \enspace \undergrouppla{\ldots xyz} \]</code>

12-3-30

With the option `frenchmath` you set the default style in math mode for rendering uppercase Latin and all Greek letters to upright. Latin lowercase glyphs remain italic. You can still get the italic uppercase Latin glyphs by using `\mathnormal`.

<code>\usepackage{newpxtext}</code>	<code>\usepackage{newpxtext}</code>
<code>\usepackage{newpxmath}</code>	<code>\usepackage[frenchmath]{newpxmath}</code>
$\mathrm{A} = \alpha + \beta < A_k$	$A = \alpha + \beta < \mathnormal{A}_k$

12-3-31

12-3-32

If you want to follow the ISO style recommendations, you can set all uppercase Greek letters slanted by using the option `slantedGreek`. In any case, all commands to access Greek letters (upper or lowercase) have a variant to explicitly access the upright form by prepending `up` to the command name, e.g., `\upDelta`, `\upOmega`, `\upalpha`, `\upbeta`, etc.

The `newpxmath` package offers the same selection of blackboard bold math alphabets as `newtxmath` including the options `varbb` and `vvarbb` for a preselection and the commands `\vmathbb` and `\vvmathbb`.

<code>\usepackage{newpxtext}</code>	<code>\usepackage{newpxtext}</code>
<code>\usepackage{newpxmath}</code>	<code>\usepackage[vvarbb]{newpxmath}</code>
$\mathbb{A}N \text{ (default)} < \mathbb{A}N < \mathbb{A}N$	$\mathbb{A}N \text{ (default)} < \mathbb{A}N < \mathbb{A}N$

12-3-33

12-3-34

The subscript correction code is also available with the `newpxmath` when you specify `subscriptcorrection`. The default adjustments are more subtle compared to those made for other fonts, but still visible.

<code>\usepackage{newpxmath}</code>	<code>\usepackage[subscriptcorrection]{newpxmath}</code>
$x_j f A \rightarrow x_j \neq y_f \neq z_A$	$x_j f A \rightarrow x_j \neq y_f \neq z_A$

12-3-35

12-3-36

Michael offers only one alternative glyph in his version of the PX fonts: you can have either a math italic *g* (default) or, by specifying the option `varg`, this *g* shape.

12.3.6 mathpazo — Another Palatino-based approach for math

A package named `mathpple` supporting Adobe Palatino with matching math fonts was originally developed by Walter Schmidt (1960–2021) based on earlier work by Aloysius Helminck. It was built on the virtual font mechanism, combining symbols from Palatino, Symbol, Euler, and CM Math. Because these fonts only partly match the style of Palatino, Diego Puga developed a set of Type 1 fonts (Pazo Math) intended to repair the defects apparent in the initial `mathpple` solution.

The Pazo Math fonts contain glyphs that are unavailable in Palatino and for which Computer Modern or glyphs from Symbol look odd when combined with Palatino. These include a number of math glyphs, the uppercase Greek alphabet (upright and slanted), a blackboard bold alphabet, as well as several other glyphs (such as the euro symbol) in regular and bold weights and upright and slanted shapes.

The fonts are accessible with the `mathpazo` package developed by Diego Puga and Walter Schmidt as part of the PSNFSS collection. It makes Palatino the document text font and provides a math setup that works by using virtual fonts accessing Palatino Italic, the Pazo Math fonts, and CM fonts (for the remaining symbols).

An example showing a trigonometric function:

$$\sin \frac{\alpha}{2} = \pm \sqrt{\frac{1 - \cos \alpha}{2}}$$

12-3-37 Scripts: $A \neq \mathcal{A} \neq \mathbb{A}$.

`\usepackage{mathpazo}`

An example showing a trigonometric function:

`\[\sin \frac{\alpha}{2} = \pm \sqrt{\frac{1 - \cos \alpha}{2}} \]`

Scripts: `$ A \neq \mathcal{A}`
`\neq \mathbb{A} $.`

The package supports the option `slantedGreek` to make uppercase Greek letters slanted instead of upright (the default). In either case the two extra commands `\upDelta` and `\upOmega` print an upright Δ and Ω , respectively. The package also provides the functionality of the `exscale` package.

Pazo Math has bold font variants, but in contrast to the PX fonts, it does not offer dedicated fonts replacing the American Mathematical Society symbol fonts. Thus, the latter are unavailable (unless you additionally load `amssymb`), and they do not change their weight in a bold context if that package is loaded.

Bold is easy to achieve: $\alpha \neq A$. It also blends in well: $A \neq \mathbf{A} = \alpha - \gamma$.

`\usepackage{mathpazo,bm}`

Bold is easy to achieve: `\{\boldmath$\alpha \neq A$}`. It also blends in well:

`$A \neq \mathbf{A} = \bm{\alpha} - \bm{\gamma}$.`

As mentioned above, the Pazo Math fonts contain a blackboard bold alphabet, which can be accessed through the math alphabet identifier `\mathbb`. The font contains the uppercase Latin letters and the digit “1”. Be careful, however: all other digits are silently ignored!

ABCDEFGHIJK 1

`\usepackage{mathpazo}`

`$\mathbb{ABCDEFGHIJK}$ $\mathbb{0123}$`

If `\mathbb` should select a different alphabet, provided by some other package, it is best to suppress the Pazo Math one by using the option `noBBppl` when loading it.

Commercial Palatino fonts

The package also offers two additional options that deal with the use of commercially available Palatino fonts¹ for the text font: `sc` selects Palatino with true small capitals (font family name `pp1x`), and `osf` selects Palatino with small caps and oldstyle numerals (font family name `pp1j`) instead of basic Palatino (`pp1`).

12.3.7 notomath — Setting up Noto fonts for math and text

The Noto fonts is a huge collection of text fonts in Serif, Sans, and Mono designs available as OpenType fonts for many languages and scripts across the world. There are also Type 1 versions in T1 and other encodings (see Table 10.14 on page 28), and these are supported by Bob Tennent's `noto` package.

As part of `newtxmath` (with the option `noto` or `notosans`) Michael Sharpe provides math support for the Noto families; thus, in principle, his package, together with Bob's, would be sufficient to set a whole document in Noto Serif or Noto Sans. There are, however, a few wrinkles that make combining them nicely a bit awkward. Michael, therefore, offers `notomath` as a simple frontend package that does all necessary work for you behind the scenes.

If you want a document in Noto Serif, all you have to do is to load the package without options. This sets up Noto Serif for the body text and Noto Sans for `\textsf`. Both families are slightly scaled down to better fit with the mathematical symbols.

If instead you want Noto Sans as your main document font, add the option `sfdefault`. This changes the `\familydefault` but leaves the `\rmdefault` untouched; thus, `\textrm` still produces Noto Serif.

An example showing a trigonometric function:

$$\sin \frac{\alpha}{2} = \pm \sqrt{\frac{1 - \cos \alpha}{2}}$$

Scripts: $\mathcal{A} \neq \mathscr{A} \neq \mathfrak{A} \neq \mathbb{A}$.

`\usepackage[sfdefault]{notomath}`

An example showing a trigonometric function:

`\[\sin \frac{\alpha}{2} =`
`\pm \sqrt{\frac{1 - \cos \alpha}{2}} \]`

Scripts: `\mathcal{A}` `\neq` `\mathscr{A}`

`\neq` `\mathfrak{A}` `\neq` `\mathbb{A}` `\mathbb{A}` `\mathbb{A}`

12-3-40

Note that the typewriter family is not set up — the package uses whatever has already been set up when it is loaded. Thus, to be able to use the typewriter font in text also with math (via `\mathtt`), you should do the typewriter setup first. However, if you want to use Noto Mono as the typewriter font, you can simply specify the option `mono`. This then loads and scales down the family appropriately.

Package options that are relevant to the `noto` package can be given to `notomath`, which passes them on, e.g., `oldstyle` or `proportional` to alter the figure style. Similarly, the general options for `newtxmath` can all be given to `notomath` too, e.g., `varbb` or `upint`, but not those that change the math italic glyphs, e.g., `stix2`.

Figure 12.38 on page 287 shows a sample page using a Noto Serif setup, and in Figure 12.50 on page 295 you can study the same sample using Noto Sans instead.

¹These fonts are commercially available and are *not* part of the Base 35 fonts.

12.4 unicode-math — Using Unicode math fonts

The original motivation for developing \TeX engines that understand Unicode and accept UTF-8 input was the desire to use text fonts with more than 256 addressable glyphs. While the engines also supported such bigger fonts for use in formulas, this was of little relevance, simply because \TeX requires special attributes for fonts used in math, and no fonts, other than a few 8-bit fonts tailored for use with \TeX , offered this.

Furthermore, Unicode itself did not explicitly encode math symbols, except for very common ones also found in typical text fonts or that were a carry-over of 8-bit input encodings — i.e., keyboard layouts used across the world. Consequently, there was little incentive for devising a set of extended font encodings for mathematics; after all, there was no standard to follow, and any change would involve a huge effort. Thus, for a long time, all engines followed the traditional 8-bit font setup for typesetting as originally devised by Donald Knuth and only marginally changed since the eighties.¹

This started to change when mathematical symbols finally got embraced by the Unicode Consortium and code points for all standard symbols in use with \TeX and many more got defined. Once that had happened, the door of opportunity opened, and the first Unicode-encoded math fonts appeared not long after. Even though the \TeX world was the driving force in this adoption into Unicode, the focus of the first such fonts was by no means \TeX (but commercial systems such as Word); in fact, the new fonts initially missed crucial font parameters to make them usable with \TeX . However, that changed too over time, and now there a dozen or more free and commercial Unicode Math fonts that you can use for typesetting with \TeX .

If you have read Chapter 9, then you know that it is not enough to have fonts for math and \TeX engines that can access them. You also need hundreds of definitions that make commands (such as `\sum` or `\alpha`) fetch the right glyph from the correct slot in the appropriate font and apply the \TeX magic to make it become a binary, relational, or whatever math symbol. Obviously, in Unicode fonts the glyphs are stored in completely different places than in the 8-bit fonts to which the \LaTeX math commands are tailored to, so nothing would work if you load such a font.

To say it differently: in the past making a new symbol font available for use with \TeX meant (re)encoding the font so that it used the same slots as Computer Modern Symbol (`cmsy`), and then all \LaTeX math commands automatically selected the right glyphs. This is what the packages provide that we discussed in the previous section.

Now, with Unicode-encoded fonts, the \LaTeX commands have to change instead to make everything work with the new font setup, and this is what `unicode-math` by Will Robertson is undertaking for you, and which is the subject of this section.

Unicode engines

To use the `unicode-math` package, you need a Unicode engine, e.g., $\text{Lua}\TeX$ or $\text{Xe}\TeX$. Thus, the remainder of this section should be inside a box like this —

¹The fact that Don's fonts are really 7-bit fonts (leaving half of the available slots unused) was of some considerable concern, but the attempt to develop a set of real 8-bit encodings for math never got beyond the theoretical work [203] and a single prototype implementation using virtual fonts — the obstacles in introducing this and getting it embraced and used everywhere proved to be too large. But this work was not in vain, because it helped with the Unicode adoption later.

which is not done to avoid straining your eyes.

As a first simple example: all you need in order to typeset using Unicode Math fonts is to load the package and use a Unicode engine. Without further adjustments this typesets your document in Latin Modern Math OpenType fonts.

An example showing a trigonometric function:

$$\sin \frac{\alpha}{2} = \pm \sqrt{\frac{1 - \cos \alpha}{2}}$$

Scripts: $\mathcal{A} \equiv \mathcal{A} \neq \mathfrak{A} \neq \mathbb{A}$.

`\usepackage{unicode-math}`

An example showing a trigonometric function:

`\[\sin \frac{\alpha}{2} =`
`\pm \sqrt{\frac{1 - \cos \alpha}{2}} \]`

Scripts: `\mathcal{A}` `\equiv` `\mathscr{A}`
`\neq` `\mathfrak{A}` `\neq` `\mathbb{A}` `$`.

12-4-1

So what do you gain by loading the package (after all, Latin Modern is the default font for \LaTeX when using a Unicode engine)? The answer is that without making further adjustments (e.g., loading a different Unicode Math font), there is not much gain that it is immediately visible. You see that `\mathbb`, `\mathscr`, and `\mathfrak` are available without loading an extra package, but that is about all.¹

But there are already now invisible but important differences between the output of the above example and that of the similar ones from the previous section. These become noticeable if you take the PDF of the examples and copy and paste parts of the formula into a different application (or into a new document). If you use Example 12-4-1, then the α , for example, copies as the Unicode character U+1D6FC (*Mathematical Italic Small Alpha*), \neq copies as U+2260 (*Not Equal To*), and the three different “A” characters copy as U+1D49C (*Mathematical Script Capital A*), U+1D504 (*Mathematical Fraktur Capital A*), and U+1D538 (*Mathematical Double-Struck Capital A*), respectively. That is, they all carry their mathematical meaning as part of their Unicode character information with them.

If on the other hand you started from Example 12-3-37, then the α is pasted as a *Greek Small Alpha* (a text character) or even as an “a”, the \neq as \neq or worse, and the different capital A’s as simple identical ASCII A’s; i.e., the material becomes unusable for further processing. For the question of accessible PDFs, this makes quite a difference.

12.4.1 Math alphabets revisited

Math alphabets as used in \LaTeX were introduced in Section 9.4.1 on page 677 and further discussed in Section 12.1 in this chapter. In a nutshell, each is related to a font that has in its ASCII slot positions for A to Z (and sometimes a to z) glyphs that are suitable as special alphabetic letters in formulas, e.g., a calligraphic alphabet such as \mathcal{ABC} These alphabets fall into two distinct groups. There are those where each glyph is always intended to be used by its own, i.e., `\mathbb`, `\mathcal`, `\mathfrak`, `\mathnormal`, and `\mathscr`. The side-bearing of each glyph is specially adjusted to give them enough room when used as a single symbol in a formula, and that makes

¹As you see, `\mathscr` is in fact by default nothing more than a different name for `\mathcal`.

them often unsuitable and uneven looking, if you try to form words with them; e.g., while you could use `\mathcal` to typeset *CALLIGRAPHY*, it is clearly not what this alphabet was intended for.

The second group are those math alphabets that have a dual purpose. They can be used to typeset a single alphabetic character, e.g., $\forall g \in G$, but alternatively can also be used to properly typeset words or word fragments within a formula, e.g., V_{\min} . In this group we have `\mathbf`, `\mathit`, `\mathrm`, `\mathsf`, and `\mathtt`, and they all point to text fonts, which means that they provide proper kerning and ligatures if their argument consists of more than one character. The difference to the corresponding `\text{...}` commands (which can also be used in formulas) is that they do not change fonts based on surrounding conditions. For example, `\mathrm` is usually used to build the textual operators, such as \lim or \max , and it always produces the same roman letters in all formulas no matter what.

When the Unicode Consortium extended its support for mathematics, this dual rôle of some of the `\math{...}` alphabet commands in \LaTeX turned out to be somewhat of a problem. In the Unicode block “Mathematical Alphanumeric Symbols” U+1D400 to U+1D7FF, Unicode places Latin and Greek letters as separate mathematical alphabets. The description in the Unicode standard for this block reads:

Mathematical Alphanumeric Symbols

To be used for mathematical variables where style variations are important semantically. For general text, use standard Latin and Greek letters with markup.

Thus, the use of `\mathsf{G}` should produce U+1D5A6 (*Mathematical Sans-Serif Capital G*) in the PDF output, whereas `\mathsf{min}` should produce ordinary Latin letters, i.e., U+006D, U+0069, and U+006E.

To cater for this additional complexity, `unicode-math` introduced `\symsf` and similarly named commands that take one argument and expect it to contain a single Latin character from the ranges A...Z, a...z, or 0...9. These commands then output the corresponding character from the “Mathematical Alphanumeric Symbols” block of Unicode. Where applicable, e.g., for `\symbf`, they also accept commands such as `\alpha` or `\Omega` to produce Greek mathematical letters from this block. Table 12.1 shows the supported set of characters for the different `\sym{...}` commands — as you can see, Unicode is unfortunately somewhat selective in what is offered.

<code>\symrm{char}</code>	<code>\symbf{char}</code>	<code>\symsf{char}</code>	<code>\symtt{char}</code>
---------------------------	---------------------------	---------------------------	---------------------------

These four commands select an appropriate symbol for a given *char* from the mathematical alphanumeric symbols block of Unicode. `\symrm` and `\symtt` are always set upright; for the other two the result is either upright or italic depending on the chosen style selected through the package keys `bold-style` and `sans-style`; see Section 12.4.2 on page 257. There is also `\symnormal`, but this is essentially the same as just typesetting *char*.

<code>\symup{char}</code>	<code>\symsfup{char}</code>	<code>\symbfup{char}</code>	<code>\symbfsfup{char}</code>
<code>\symit{char}</code>	<code>\symsfit{char}</code>	<code>\symbfit{char}</code>	<code>\symbfsfit{char}</code>

If you want to explicitly set the style for a *char* regardless of the document setup, you can do so with one of these eight commands; e.g., `\symsfit{\delta}` generates a sans serif italic Greek delta, even if the `sans-style` is set to upright. In a similar fashion you can overwrite the package's bold-style setting and request a *char* in one of the above bold styles. Note that not all imaginable combinations are supported, but only those encoded by Unicode.

<code>\symbb{char}</code>	<code>\symbbit{char}</code>	<code>\symfrak{char}</code>	<code>\symbffrak{char}</code>
<code>\symcal{char}</code>	<code>\symbfcal{char}</code>	<code>\symscr{char}</code>	<code>\symbfscr{char}</code>

The traditional math alphabets offer fewer variations than those associated with text fonts, and in many font setups they support only uppercase letters. Note that the blackboard bold italic (`\symbbit`) is supported only for the letters D, d, e, i, and j in Unicode, so it is of comparably little use. Also important to know is that by default `\symcal` and `\symbfcal` are only synonyms for `\symscr` and `\symbfscr`.

In the next example, most of the commands discussed above are used, and the characters are dancing horribly in front of your eyes. Still, it is worth looking at the example from line to line and observing what changes and why.

```

\usepackage{amsmath,unicode-math}
\begin{gather*}
  a,b,X,Y,Z,\pi,\Gamma
  \symrm{a},\symbf{b},\symsf{Y},X,\symtt{Z},\symrm{\pi},\symit{\Gamma} \\\
  \symbfsfit{a},\symbfit{b},X,\symbfsfit{Y},\symbfsfup{Z},
  \symbfup{\pi},\symbfit{\Gamma} \\\
  \symfrak{a},\symbffrak{b},\symbb{X},\symscr{Y},\symbfscr{Z},
  \symbfit{\pi},\symbfsf{\Gamma} \\\
  \symbb{0},\symbb{1},\symbb{2},\symbb{3},\dots,
  \symbfsfup{7},\symbfsfup{8},\symbfsfup{9}
\end{gather*}

```

a, b, X, Y, Z, π, Γ
a, b, Y, X, Z, π, Γ
a, b, X, Y, Z, π, Γ
a, b, ℵ, ℶ, ℷ, π, Γ
0, 1, 2, 3, ..., 7, 8, 9

12-4-2

If the default set of math alphabet, i.e., `bb`, `bf`, `cal`, `frak`, `sf`, and `tt`, are not sufficient, you can declare additional ones for 8-bit fonts for which you know the NFSS values with `\DeclareMathAlphabet`; see Section 9.4.1 on page →I 677. For Unicode fonts use `\setmathfontface` instead.

<code>\setmathfontface{cmd}{font name} [font features]</code>

The *cmd* can be any command name, though something like `\math...` or `\mathtext...` would be customary and fit well with other math alphabets.¹ The *font name* and *font features* are describing the Unicode (text) font and are passed to the `fontspec` package for loading; see Section 9.6 on page →I 705. In the following example we define `\mathhw` and assign the handwriting font *Miama Nueva* to it. Because of

¹There is a good chance that L^AT_EX adopts both `\sym...` and `\mathtext...` as the new standard for all engines during the next years — this is currently under discussion to bridge the gap between 8-bit and Unicode engines.

Command	Math alphabet			Affected characters			
	family	series	shape	Latin	Greek	Numeral	
<code>\symnormal</code>	serif	medium	^(a)	•	•	(•)	A (•) indicates that numerals are always set upright.
<code>\symbf</code>		bold	^(b)	•	•	•	
<code>\symrm^(c)</code>		medium	upright	•		•	
<code>\symsf</code>	sans serif	medium	^(d)	•		•	^(a) The shape depends on the setting for math-style and may differ for different characters.
<code>\symtt</code>	typewriter	medium	upright	•		•	
<code>\symup</code>	serif	medium	upright	•	•	•	^(b) The shape depends on the setting for bold-style and may differ for different characters.
<code>\symit</code>			italic	•	•	(•)	
<code>\symbfup</code>		bold	upright	•	•	•	
<code>\symbf^(c)</code>	sans serif	medium	upright	•		•	^(c) This is just a synonym for <code>\symup</code> .
<code>\symsfup</code>			italic	•		(•)	
<code>\symsf^(d)</code>		bold	upright	•	•	•	
<code>\symbfsfup</code>			italic	•	•	(•)	^(d) The shape depends on the setting for sans-style and may be upright or italic throughout.
<code>\symbfsf^(e)</code>	blackboard	medium	upright	•		•	
<code>\symbbit</code>		medium	italic	• ^(e)			
<code>\symscr</code>	script/cal ^(f)	medium	upright	•			^(e) There is only support for the characters D, d, e, i, and j in Unicode.
<code>\symbfscr</code>		bold	upright	•			
<code>\symfrac</code>	fraktur	medium	upright	•			^(f) By default <code>\symcal</code> and <code>\symbcal</code> just are synonyms for <code>\symscr</code> and <code>\symbfscr</code> .
<code>\symbffrak</code>		bold	upright	•			

Table 12.1: Behavior and argument scope of `\sym...` commands

its large design size we have to rigorously scale it down to match the size of Latin Modern used for the rest of the glyphs.

12-4-3

$$\begin{array}{l}
 ABCDEFG \neq ABCDEF \mathcal{G} \\
 X_{\text{writing}}^{\text{Hand}} \not\approx X_{\text{writing}}^{\text{Formal}}
 \end{array}$$

```

\usepackage{amsmath,unicode-math}
\setmathfontface{\mathhw{Miama Nueva}}[Scale=.75]
\begin{align*}
\mathhw{ABCDEFG} &\&\neq \mathcal{ABCDEFG} \\
X^{\mathhw{Hand}}_{\mathhw{writing}} &\&\not\approx X^{\mathrm{Formal}}_{\mathit{writing}}
\end{align*}

```

Note that for alphabets defined in this way, there are no dedicated Unicode ranges, so they are all placed as ordinary Latin characters into the PDF.

12.4.2 Adjusting the formula style

By default formulas typeset with T_EX use an italic alphabet for variables denoted by Latin characters. Lowercase Greek letters are also in italic, but uppercase Greek is set upright. While this is a widely accepted style, it is by no means the only one in use. ISO recommends the use of italics throughout (i.e., uppercase Greek in italics

A choice of italic or upright Greek and Latin letters

All five package keys also support the special value `literal`, which means that `unicode-math` does not undertake any input normalization (e.g., typeset Latin letters in italic) but uses the style given by the source character; e.g., if it is a *Latin Small X* (U+0078), it typesets an upright *x*, but if it is *Mathematical Italic Small X* (U+1D465), it typesets it as *x* in the formula; see the package documentation when this might be useful. You can also force “literal” style through `\symliteral`, which undoes the effect of `\symnormal`.

Forcing literal input style

12.4.3 Setting up Unicode math fonts

Up until now we have loaded `unicode-math`, which gives us the features and commands described, but our documents are still typeset using Latin Modern, because that is \TeX 's default in Unicode engines. If we want to use a different Unicode math font, we need to tell the package about it.

Changing the main font for math formulas

```
\setmathfont{family}[feature-list]
```

This declaration sets up the math font *family* to be used (which needs to be a specially prepared font). The command is modeled after the declarations provided by the `fontspec` package, e.g., `\setmainfont`, and you may want to review Section 9.6.1 on page 706 to familiarize yourself with the different ways to find and specify the *family* name and the various features that you can put into the *feature-list*.

There are a few keys that are specific to setting up math fonts, and those are discussed below. However, it is often enough to just give the right *family* name, as shown in the next example where we use Fira Sans and Fira Math for typesetting.

An example showing a trigonometric function:

$$\sin \frac{\alpha}{2} = \pm \sqrt{\frac{1 - \cos \alpha}{2}}$$

```
\usepackage{fontspec} \setmainfont{Fira Sans}
\usepackage{unicode-math} \setmathfont{Fira Math}
```

An example showing a trigonometric function:

```
\[ \sin \frac{\alpha}{2} =
\pm \sqrt{\frac{1 - \cos \alpha}{2}} \]
```

Scripts: $A \neq \mathbb{A}$; no other math alphabets are available in Fira Sans.

Scripts: $\$A \neq \text{\textbb{A}} \$$; no other math alphabets are available in Fira Sans.

12-4-5

Well-known mathematical functions (such as $\sin \alpha$ and $\cos \beta$) are usually typeset in a font distinct from surrounding letters denoting variables in a formula. In \TeX such functions are declared with `\DeclareMathOperator`; see Section 11.6.2 on page 192. They all use the same fixed font, typically upright roman (e.g., `\mathrm`). With `\setoperatorfont{alphabet}` the `unicode-math` package offers a simple way to choose a different math alphabet for this task. For example, after `\setoperatorfont{\mathsf}` you get $\sin \alpha$ and $\cos \beta$ in your formulas.

Adjusting the “operator” font

Adjusting parts of the font setup

Simply adding a single `\setmathfont` declaration works fine if the Unicode math font that you use implements all the math glyphs that you are interested in. However, this may not be the case. You may find that individual characters or whole alphabets

Making adjustments for a range of characters

are missing, in which case you need to provide some additional declarations. For example, the Fira Math fonts used above do not offer a script or a fraktur math alphabet, and many examples in Section 12.5 miss individual symbols that need to be provided from elsewhere. For this you can use the `range` key.

In the next example we repeat the setup from above but add a second declaration that loads the STIX 2 math font. By specifying a `range`, we tell the loader that it should be replacing only the ranges `frak` and `scr` and leave the rest of the math setup alone. As a result we can now typeset in all three math alphabets (though our choice of using the STIX font alphabets is not that great).

```
\usepackage{fontspec}      \setmainfont{Fira Sans}      % text setup
\usepackage{unicode-math} \setmathfont{Fira Math}      % math setup
\setmathfont{STIX Two Math Regular}[range={frak,scr}] % replacement
```

Scripts: $A \neq \mathcal{A} \neq \mathbb{A} \neq \mathfrak{A}$ Scripts: $\$A \backslash neq \backslash symscr{A} \backslash neq \backslash symbb{A} \backslash neq \backslash symfrak{A} \$$

12-4-6

The previous example showed “named” ranges as the value for the `range` key. The supported names are `bb`, `bbit`, `bfcalf`, `bffrak`, `bfit`, `bfscr`, `bfsfit`, `bfsfup`, `bfup`, `cal`, `frak`, `it`, `scr`, `sfit`, `sfup`, `tt`, and `up` — hopefully all self-explanatory.

*Replacing individual
characters or adding
missing ones*

They are useful if you want to include a whole alphabet from a different font, but perhaps you need to add only a few missing characters. In that case the syntax is a comma-separated list of hexadecimal slot numbers, e.g., `range={"2A04,"2A0C}`, which we need in Figure 12.26 on page 279 to make the example work. Note that you need braces around the value if it contains commas.

If you want to load a consecutive range (one that is not matching any of the named ones), you can simplify the input, by giving the start and end hexadecimal codes separated by a hyphen instead of a comma, e.g., `"27D0-"27EB`. There are further (less often needed) syntax variations: see the package documentation if the above does not seem sufficient.

*Script and
scriptscript fonts
and features*

Characters in formulas come in three sizes, e.g., a^{a^a} (text, script, and second-order script size). In many situations, \TeX simply loads the same font at three different sizes, but this is not always the case. Some font families, such as Computer or Latin Modern, have separate optically adjusted fonts for different sizes and thus for different sizes different fonts are loaded (see Figure 9.6 on page 1657 for an example). With OpenType fonts, such optical adjustments may all be bundled in a single font and selected through font features — for example, with Cambria Math.

To cater for both approaches (or a combination thereof), `unicode-math` offers the keys `script-font` and `sscript-font` to select alternate fonts for the index sizes and `script-features` and `sscript-features` to apply individual feature lists for them. The keys are preset with `Style=MathScript` and `Style=MathScriptScript`, respectively, which are the correct settings in most cases.

*Providing several
math versions*

In standard \LaTeX you can switch “math versions” (different setups for formulas) using `\mathversion{version}`. By default, two *versions* are provided, `normal` and `bold`, and with the mechanisms described on Section 9.8.5 on page 1753 you can define further versions, if necessary. This concept of versions is also supported for Unicode fonts, but because these fonts are loaded differently, the declaration mechanism differs too. To indicate that a Unicode font is for a specific *version*, use

```
\setmathfont{family}[version=version,... other features...]
```

12.5 A visual comparison of different math setups

In this section we repeatedly show the same sample text, typeset with different font setups for math and text. It assumes `amsmath` and with `pdfTeX` also the `bm` package.

We start by briefly discussing the input used, highlighting points to look at in the examples with blue color. At the beginning of the example file, we define `\ibinom`, which is used later. This is followed by the section title, which differs in each example, denoted here with three dots:

```
\newcommand\ibinom[2]{\genfrac\lbrace\rbrace{0pt}{}{#1}{#2}}
\section*{...}
```

In the first paragraph we use a `\smash` around the first inline formula in order to avoid it pushing the baseline apart. One point to keep track of in the output is the different math alphabets (always used with the letter Q), and you should compare their results — here we use the calligraphic one. Also noteworthy are the different integrals: in some examples they are shown upright.

```
First some large operators both in text:
\smash{$ \ibint\limits_{\mathcal{Q}} f(x,y,z)\,dx\,dy\,dz $} and
$ \prod_{\gamma\in\Gamma_{\widetilde{C}}}
\partial(\widetilde{X}_{\gamma}) $; and also on display:
```

The first line of the split equation is deliberately long so as to show differences in widths in different font setups; it is a little wider than the space needed with Computer Modern fonts. `\ibint` is marked blue, because it is missing in some OpenType fonts. The output line also shows two further “Q”s, both bold, but one produced with `\mathbf`, and the other with `\bm` from the `bm` package.¹

```
\begin{equation} \begin{split}
\ibint\limits_{\mathbf{Q}} f(w,x,y,z)dwxdydz
& \leq \oint_{\bm{\partial Q}} f' \left( \max \left\{ \frac{w}{w^2 + x^2} \right. \right. \\
& \quad \left. \frac{z}{y^2 + z^2} \right. \\
& \quad \left. \left. \frac{w}{w^2 + x^2} \right\} \right) \right) \end{split}
```

The three symbols \mathbb{Q} (from core \TeX) and \mathbb{Q} and \mathbb{Q} (from the American Mathematical Society symbol set) are all problematical (i.e., missing) in one or the other OpenType font and there are some further “Q”s. This time we have two blackboard bold (`\mathbb`) and another ordinary bold one. Further down we have marked `\nu` and `v` blue, as an example of glyphs that may be hard to distinguish in some font families.

```
& \precapprox \biguplus_{\mathbb{Q}} \bar{\mathbf{Q}}
\left[ f^{\ast} \left( \frac{\left\{ \text{moustache} \mathbb{Q} (t) \right\}}{\sqrt{1 - t^2}} \right) \right]_{t=\alpha}^{t=\vartheta} - ( \Delta + \nu - v )^3
\end{split} \end{equation}
```

¹In the Unicode font examples `\symbf` is used instead of `\bm`.

The next paragraph gives you an indication for the running length of the text and math fonts if you take a look at where the two words in blue show up:

For x in the open interval $]-1, 1[$ the infinite sum in Equation~\eqref{eq:binom1} is **convergent**; **however**, this does not hold throughout the closed interval $[-1, 1]$.

In the last equation we have two places where there may be spacing issues with superscripts and another blackboard alphabet character, this time “N”.

```
\begin{equation}
(1 - x)^{-k} = 1 + \sum_{j=1}^{\infty} (-1)^j \binom{k}{j} x^j
\text{\quad for } k \in \mathbb{N}; k \neq 0. \quad \label{eq:binom1}
\end{equation}
```

Figure 12.1 shows the sample text typeset in Computer Modern text and math fonts — the default font setup in L^AT_EX. We reuse this input throughout the remainder of this section to exhibit different font setups and allow you to compare them with each other. The only thing that changes is the section title.

The remaining examples (Figures 12.2 to 12.51) in this section follow the classification we introduced in Chapter 10. The fonts in some groups, e.g., Humanist serif, have no matching math support at all, in which case we bypass them, but otherwise

Mathematical typesetting with Computer Modern

First some large operators both in text: $\iiint_{\mathbb{Q}} f(x, y, z) dx dy dz$ and $\prod_{\gamma \in \Gamma_{\tilde{C}}} \partial(\tilde{X}_{\gamma})$; and also on display:

$$\begin{aligned} \iiint_{\mathbb{Q}} f(w, x, y, z) dw dx dy dz &\leq \oint_{\partial Q} f' \left(\max \left\{ \frac{\|w\|}{|w^2 + x^2|}; \frac{\|z\|}{|y^2 + z^2|}; \frac{\|w \oplus z\|}{\|x \oplus y\|} \right\} \right) \\ &\approx \bigcup_{\mathbb{Q} \in \mathbb{Q}} \left[f^* \left(\frac{\int \mathbb{Q}(t)}{\sqrt{1-t^2}} \right) \right]_{t=\alpha}^{t=\vartheta} - (\Delta + \nu - v)^3 \end{aligned} \quad (1)$$

For x in the open interval $]-1, 1[$ the infinite sum in Equation (2) is convergent; however, this does not hold throughout the closed interval $[-1, 1]$.

$$(1 - x)^{-k} = 1 + \sum_{j=1}^{\infty} (-1)^j \left\{ \begin{matrix} k \\ j \end{matrix} \right\} x^j \quad \text{for } k \in \mathbb{N}; k \neq 0. \quad (2)$$

12-1-fig

Figure 12.1: Sample page typeset with Computer Modern text + math fonts

the order is preserved so that you can easily hunt for similar text fonts to go with a certain math setup or vice versa.

Each setup is explained in the accompanying text, e.g., on some occasions we use special package options or have to substitute a few glyphs, because they are missing in the font.¹

Many font setups can be used both with pdfTeX or Unicode engines — in this case we show the pdfTeX version in the book. With fonts that are not usable with pdfTeX, the sample has been processed with LuaTeX. This is explained in the text, but also visually indicated by displaying the figure caption with a gray background, e.g., Figure 12.5.

12.5.1 Garalde (Oldstyle) serif fonts with math support

Math support for the Crimson family of fonts designed by Sebastian Kosch is provided by Michael Sharpe through his `newtxmath` package by passing it the option `cochineal`. To set up matching text fonts you can use either `CrimsonPro` or `cochineal`; see Section 10.4.3 on page 40 for the differences. For Figure 12.2 we used the following simple setup:

*Crimson, Crimson
Pro, and Cochineal*

```
\usepackage{cochineal} \usepackage[cochineal]{newtxmath}
```

¹Especially with OpenType fonts that can happen rather easily. It is therefore quite important to use `\tracinglostchars=3` in your document preamble to receive an error message in such a case.

Mathematical typesetting with Cochineal

First some large operators both in text: $\iiint_Q f(x, y, z) dx dy dz$ and $\prod_{\gamma \in \Gamma_{\tilde{C}}} \partial(\tilde{X}_{\gamma})$; and also on display:

$$\begin{aligned} \iiint_Q f(w, x, y, z) dw dx dy dz &\leq \oint_{\partial Q} f' \left(\max \left\{ \frac{\|w\|}{|w^2 + x^2|}, \frac{\|z\|}{|y^2 + z^2|}, \frac{\|w \oplus z\|}{\|x \oplus y\|} \right\} \right) \\ &\approx \bigcup_{Q \in \mathcal{Q}} \left[f^* \left(\frac{\int \mathcal{Q}(t) \, t}{\sqrt{1 - t^2}} \right) \right]_{t=\alpha}^{t=\beta} - (\Delta + \nu - \nu)^3 \end{aligned} \quad (1)$$

For x in the open interval $] -1, 1[$ the infinite sum in Equation (2) is convergent; however, this does not hold throughout the closed interval $[-1, 1]$.

$$(1 - x)^{-k} = 1 + \sum_{j=1}^{\infty} (-1)^j \begin{Bmatrix} k \\ j \end{Bmatrix} x^j \quad \text{for } k \in \mathbb{N}; k \neq 0. \quad (2)$$

12-5-fig

Unicode engines

Figure 12.5: Sample page typeset with Garamond Libre + Garamond Math fonts

There are many revivals of the fonts designed by Claude Garamond, and a number of them have been made freely available for use with T_EX; see Sections 10.4.4 to 10.4.7.

A number of setups based on Garamond

We show three combinations: EB Garamond designed by Georg Duffner and Octavio Pardoin for math and text (Figure 12.3); Garamondx, a reworking of URW's Garamond by Michael Sharpe, in math and text (Figure 12.4); and a combination of Garamond Libre by D. Benjamin Miller for text and Garamond Math by Yuansheng Zhao and Xiangdong Zeng (Figure 12.5). The setup used for EB Garamond was:

```
\usepackage[lining,semibold,scaled=1.05]{ebgaramond}
\usepackage[ebgaramond,varbb,subscriptcorrection]{newtxmath}
```

and somewhat simpler for Garamondx:

```
\usepackage{garamondx} \usepackage[garamondx]{newtxmath}
```

Compared to Garamondx, EB Garamond runs slightly shorter (which can be seen in the second paragraph) even though it is scaled up a bit. Otherwise, the differences are small with some differences in individual letter forms, such as the ν and the different blackboard bold alphabet.

The OpenType Garamond Math font (which offers some stylistic sets, not used) is available only for Unicode engines, and the setup that we used looks as follows:

```
\usepackage{fontspec} \setmainfont{Garamond Libre}
\usepackage{unicode-math} \setmathfont{Garamond Math}
\setmathfont{Asana Math}[range="2AB7,Scale=.84]
```

The last line shows a substitution because a character was missing — note the scaling.

Mathematical typesetting with Kp Roman Light

First some large operators both in text: $\iiint_Q f(x, y, z) dx dy dz$ and $\prod_{\gamma \in \Gamma_{\mathbb{C}}} \partial(\widetilde{X}_{\gamma})$; and also on display:

$$\begin{aligned} \iiint_Q f(w, x, y, z) dw dx dy dz &\leq \oint_{\partial Q} f' \left(\max \left\{ \frac{\|w\|}{|w^2 + x^2|}, \frac{\|z\|}{|y^2 + z^2|}, \frac{\|w \oplus z\|}{\|x \oplus y\|} \right\} \right) \\ &\approx \bigcup_{Q \in \tilde{Q}} \left[f^* \left(\frac{(\mathcal{Q}(t))}{\sqrt{1-t^2}} \right) \right]_{t=\alpha}^{t=\vartheta} - (\Delta + \nu - \nu)^3 \end{aligned} \quad (1)$$

For x in the open interval $] -1, 1[$ the infinite sum in Equation (2) is convergent; however, this does not hold throughout the closed interval $[-1, 1]$.

$$(1-x)^{-k} = 1 + \sum_{j=1}^{\infty} (-1)^j \left\{ \begin{matrix} k \\ j \end{matrix} \right\} x^j \quad \text{for } k \in \mathbb{N}; k \neq 0. \quad (2)$$

$$(1 - x)^{-k} = 1 + \sum_{j=1}^{\infty} (-1)^j \left\{ \begin{matrix} k \\ j \end{matrix} \right\} x^j \quad \text{for } k \in \mathbb{N}; k \neq 0. \quad (2)$$

12-8-fig

Unicode engines

Figure 12.8: Sample page typeset with KpRoman + Kp Math fonts

The Kp family of fonts by Christophe Caignaert is based on the Palatino design and offers full math support in all engines. On this page we show three variations. The first two use `kpfonts` for `pdfTeX`, which comes with a huge number of options for customization, out of which we have chosen seven. The setup for Figure 12.6 was this:

```
\usepackage[light,lighttext,narrowiints,frenchstyle]{kpfonts}
```

This applies lighter fonts, both for text and math, and brings multiple integrals closer together. Finally, `frenchstyle` typesets all math letters — except for lowercase Latin letters — upright (Q, γ, C, X in the first line). Figure 12.7 then used this setup:

```
\usepackage[oldstyle,oldstylenumsmath,sfmathbb]{kpfonts}
```

Here, the `oldstyle` option is responsible for the extra ligatures, e.g., in “First”, and for the `oldstylenumsmath` requests them also in math; and `sfmathbb` changes the blackboard bold alphabet to sans serif.

The final example exhibits the OpenType versions of the family, as provided by Daniel Flipo. He also offers the package `kpfonts-otf` to set them up, but for Figure 12.8 we have used `fontspec` and `unicode-math` instead, because that also shows how to combine the math fonts with other text families.

```
\usepackage{fontspec} \setmainfont{KpRoman}
\usepackage[math-style=ISO]{unicode-math} \setmathfont{Kp Math}[StylisticSet=3]
```

The feature `StylisticSet=3` sets the integral closer; for a full set of features see the font documentation or the `kpfonts-otf` package documentation.

The Kp (Johannes Kepler) fonts

Mathematical typesetting with Math Pazo

First some large operators both in text: $\iiint_Q f(x, y, z) dx dy dz$ and $\prod_{\gamma \in \Gamma_{\tilde{C}}} \partial(\tilde{X}_{\gamma})$; and also on display:

$$\iiint_Q f(w, x, y, z) dw dx dy dz \leq \oint_{\partial Q} f' \left(\max \left\{ \frac{\|w\|}{|w^2 + x^2|}, \frac{\|z\|}{|y^2 + z^2|}, \frac{\|w \oplus z\|}{\|x \oplus y\|} \right\} \right) \\ \approx \bigcup_{Q \in \tilde{Q}} \left[f^* \left(\frac{\int Q(t)}{\sqrt{1 - t^2}} \right) \right]_{t=\alpha}^{t=\theta} - (\Delta + \nu - v)^3 \quad (1)$$

For x in the open interval $] -1, 1[$ the infinite sum in Equation (2) is convergent; however, this does not hold throughout the closed interval $[-1, 1]$.

$$(1 - x)^{-k} = 1 + \sum_{j=1}^{\infty} (-1)^j \left\{ \begin{matrix} k \\ j \end{matrix} \right\} x^j \quad \text{for } k \in \mathbb{N}; k \neq 0. \quad (2)$$

12-9-fig

Figure 12.9: Sample page typeset with Palatino text + Pazo Math fonts

*Different math
setups for use with
Palatino*

The typeface Palatino was designed by Hermann Zapf (1918–2015) for the Stempel foundry in 1948 based on lettering from the Italian Renaissance. Since then it has become one of the most widely used typefaces, and probably the most popular Old Style revival in existence [26]. A number of math font setups are available for use with Palatino as the text font.

Figure 12.9 shows the freely available Pazo Math fonts (designed by Diego Puga), which can be activated with `\usepackage{mathpazo}`. It offers boldface symbols and a matching blackboard bold alphabet but does not contain specially designed shapes for the AMS symbol set; see also Section 12.3.6.

In contrast, the free PX fonts (designed by Young Ryu) comprise the complete symbol set. Shown in Figure 12.10 is the version of the fonts that was reworked by Michael Sharpe; see also Section 12.3.5 on page 248. The setup used for the example was the following simple line:

```
\usepackage{newpxtext,newpxmath}
```

For comparison Figure 12.11 combines Pagella with the Kp fonts for math using the following setup:

```
\usepackage{newpxtext} \usepackage[notext]{kpfonts}
```

The `notext` option for `kpfonts` tells the package to only set up math font support but leave the text fonts untouched.

Mathematical typesetting with Pagella/New PX

First some large operators both in text: $\iiint_Q f(x, y, z) dx dy dz$ and $\prod_{\gamma \in \Gamma_{\bar{C}}} \partial(\tilde{X}_{\gamma})$; and also on display:

$$\begin{aligned} \iiint_Q f(w, x, y, z) dw dx dy dz &\leq \oint_{\partial Q} f' \left(\max \left\{ \frac{\|w\|}{|w^2 + x^2|}, \frac{\|z\|}{|y^2 + z^2|}, \frac{\|w \oplus z\|}{\|x \oplus y\|} \right\} \right) \\ &\approx \bigcup_{Q \in \mathbb{Q}} \left[f^* \left(\frac{f(Q(t))}{\sqrt{1-t^2}} \right) \right]_{t=\alpha}^{t=\vartheta} - (\Delta + \nu - \nu)^3 \end{aligned} \quad (1)$$

For x in the open interval $] -1, 1[$ the infinite sum in Equation (2) is convergent; however, this does not hold throughout the closed interval $[-1, 1]$.

$$(1-x)^{-k} = 1 + \sum_{j=1}^{\infty} (-1)^j \left\{ \begin{matrix} k \\ j \end{matrix} \right\} x^j \quad \text{for } k \in \mathbb{N}; k \neq 0. \quad (2)$$

12-10-fig

$$(1-x)^{-k} = 1 + \sum_{j=1}^{\infty} (-1)^j \left\{ j \atop k \right\} x^j \quad \text{for } k \in \mathbb{N}; k \neq 0. \quad (2)$$

12-12-fig

Unicode engines

Figure 12.12: Sample page typeset with Pagella + Pagella Math fonts

Mathematical typesetting with Pagella/Asana

First some large operators both in text: $\iiint_{\mathbb{Q}} f(x, y, z) dx dy dz$ and $\prod_{\gamma \in \Gamma_{\mathbb{C}}} \partial(\tilde{X}_{\gamma})$; and also on display:

$$\begin{aligned} \iiint_{\mathbb{Q}} f(w, x, y, z) dw dx dy dz &\leq \oint_{\partial \mathbb{Q}} f' \left(\max \left\{ \frac{\|w\|}{|w^2 + x^2|}, \frac{\|z\|}{|y^2 + z^2|}, \frac{\|w \oplus z\|}{\|x \oplus y\|} \right\} \right) \\ &\approx \bigcup_{\mathbb{Q} \in \tilde{\mathbb{Q}}} \left[f^* \left(\frac{\mathbb{Q}(t)}{\sqrt{1-t^2}} \right) \right]_{t=\alpha}^{t=\vartheta} - (\Delta + \nu - v)^3 \end{aligned} \quad (1)$$

For x in the open interval $] -1, 1[$ the infinite sum in Equation (2) is convergent; however, this does not hold throughout the closed interval $[-1, 1]$.

$$(1-x)^{-k} = 1 + \sum_{j=1}^{\infty} (-1)^j \left\{ j \atop k \right\} x^j \quad \text{for } k \in \mathbb{N}; k \neq 0. \quad (2)$$

12-13-fig

Unicode engines

Figure 12.13: Sample page typeset with Pagella + Asana Math fonts

When it comes to Unicode engines, there are a few additional alternatives available. The T_EX Gyre foundry (Bogusław Jackowski, Piotr Pianowski, Piotr Strzelczyk) developed a set of OpenType math fonts to accompany their text fonts, one of which is Pagella Math. The sample in Figure 12.12 was produced with the following setup:

```
\usepackage{fontspec}      \setmainfont{TeX Gyre Pagella}
\usepackage{unicode-math}  \setmathfont{TeX Gyre Pagella Math}
\setmathfont{Asana Math}[range="2AB7,Scale=1.1]
```

Again, we have to fix a missing character by using a scaled version from Asana Math, but this time we have to enlarge it to get the correct size.

In the final example involving Palatino, we pair it with Asana Math by Apostolos Syropoulos. This font has no missing glyphs, so we simply load it with the help of `unicode-math`: the result is shown in Figure 12.13 on the facing page.

```
\usepackage{fontspec}      \setmainfont{TeX Gyre Pagella}
\usepackage{unicode-math}  \setmathfont{Asana Math}
```

12.5.2 Transitional serif fonts with math support

Among the transitional serif typefaces there are many with matching math support. As always, we progress in alphabetical order starting with versions of Baskerville. Figure 12.14 exhibits BaskervilleF, and Figures 12.15 and 12.16 on the next page show Baskervaldx. In all cases the math support was developed by Michael Sharpe.

Mathematical typesetting with BaskervilleF

First some large operators both in text: $\iiint_Q f(x, y, z) \, dx \, dy \, dz$ and $\prod_{\gamma \in \Gamma_{\tilde{C}}} \partial(\tilde{X}_{\gamma})$; and also on display:

$$\begin{aligned} \iiint_Q f(w, x, y, z) \, dw \, dx \, dy \, dz &\leq \oint_{\partial Q} f' \left(\max \left\{ \frac{\|w\|}{|w^2 + x^2|}, \frac{\|z\|}{|y^2 + z^2|}, \frac{\|w \oplus z\|}{\|x \oplus y\|} \right\} \right) \\ &\approx \bigcup_{Q \in \tilde{Q}} \left[f^* \left(\frac{f(Q(t))}{\sqrt{1 - t^2}} \right) \right]_{t=\alpha}^{t=\theta} - (\Delta + \nu - v)^3 \end{aligned} \quad (1)$$

For x in the open interval $] -1, 1[$ the infinite sum in Equation (2) is convergent; however, this does not hold throughout the closed interval $[-1, 1]$.

$$(1 - x)^{-k} = 1 + \sum_{j=1}^{\infty} (-1)^j \left\{ \begin{matrix} k \\ j \end{matrix} \right\} x^j \quad \text{for } k \in \mathbb{N}; k \neq 0. \quad (2)$$

12-14-fig

Figure 12.14: Sample page typeset with BaskervilleF text + math fonts

Mathematical typesetting with Baskervaldx

First some large operators both in text: $\iiint_{\mathbb{Q}} f(x, y, z) dx dy dz$ and $\prod_{\gamma \in \Gamma_{\tilde{C}}} \partial(\tilde{X}_{\gamma})$; and also on display:

$$\begin{aligned} \iiint_{\mathbb{Q}} f(w, x, y, z) dw dx dy dz &\leq \oint_{\partial Q} f' \left(\max \left\{ \frac{\|w\|}{|w^2 + x^2|}; \frac{\|z\|}{|y^2 + z^2|}; \frac{\|w \oplus z\|}{\|x \oplus y\|} \right\} \right) \\ &\approx \bigcup_{\mathbb{Q} \in \tilde{\mathbb{Q}}} \left[f^* \left(\frac{\int \mathbb{Q}(t) \setminus}{\sqrt{1 - t^2}} \right) \right]_{t=\alpha}^{t=\vartheta} - (\Delta + \nu - \nu)^3 \end{aligned} \quad (1)$$

For x in the open interval $] -1, 1[$ the infinite sum in Equation (2) is convergent; however, this does not hold throughout the closed interval $[-1, 1]$.

$$(1 - x)^{-k} = 1 + \sum_{j=1}^{\infty} (-1)^j \left\{ \begin{matrix} k \\ j \end{matrix} \right\} x^j \quad \text{for } k \in \mathbb{N}; k \neq 0. \quad (2)$$

12-15-fig

Mathematical typesetting with Bonum

First some large operators both in text: $\iiint_Q f(x, y, z) dx dy dz$ and $\prod_{\gamma \in \Gamma} \partial(\tilde{X}_\gamma)$; and also on display:

$$\begin{aligned} \iiint_{\mathfrak{g}} f(w, x, y, z) dw dx dy dz &\leq \oint_{\partial \mathfrak{g}} f' \left(\max \left\{ \frac{\|w\|}{|w^2 + x^2|}, \frac{\|z\|}{|y^2 + z^2|}, \frac{\|w \oplus z\|}{\|x \oplus y\|} \right\} \right) \\ &\lesssim \bigcup_{Q \in \bar{\mathfrak{g}}} \left[f^* \left(\frac{Q(t)}{\sqrt{1-t^2}} \right) \right]_{t=a}^{t=\vartheta} - (\Delta + \nu - \nu)^3 \end{aligned} \quad (1)$$

For x in the open interval $] -1, 1[$ the infinite sum in Equation (2) is convergent; however, this does not hold throughout the closed interval $[-1, 1]$.

$$(1-x)^{-k} = 1 + \sum_{j=1}^{\infty} (-1)^j \left\{ \begin{matrix} k \\ j \end{matrix} \right\} x^j \quad \text{for } k \in \mathbb{N}; k \neq 0. \quad (2)$$

12-17-fig

Unicode engines

Figure 12.17: Sample page typeset with Bonum + Bonum Math fonts

Figure 12.14 on page 271 was produced by loading BaskervilleF's support package [Math setups for Baskerville](#) with an option to get oldstyle numerals in text, and the math was set up using Michael's workhorse newtxmath with an appropriate option.

```
\usepackage[osf]{baskervillef} \usepackage[baskervillef]{newtxmath}
```

The showcases for Baskervaldx on the opposite page were produced in a similar fashion, except that we used a few more options and also deployed a different calligraphic math alphabet with the help of the mathalpha package:

```
\usepackage[osf]{Baskervaldx} \usepackage[baskervaldx,vvarbb]{newtxmath}
\usepackage[cal=boondoxo]{mathalfa} % \mathcal from STIX, slightly slanted
```

The setup for the combination of Baskervaldx with Times in Figure 12.16 is again simpler: `\usepackage{Baskervaldx,newtxmath}`.

The Bookman (Bonum) fonts have a matching math font for Unicode engines [Bookman math support with Unicode engines](#) produced by the T_EX Gyre foundry. Again, we have to fix a missing glyph.

```
\usepackage{fontspec} \setmainfont{TeX Gyre Bonum}
\usepackage{unicode-math} \setmathfont{TeX Gyre Bonum Math}
\setmathfont{KpMath}[range="2AB7,Scale=1.2] % difficult to find a good match
```

Mathematical typesetting with Cambria

First some large operators both in text: $\iiint_Q f(x, y, z) dx dy dz$ and $\prod_{\gamma \in \Gamma_{\tilde{c}}} \partial(\tilde{X}_{\gamma})$; and also on display:

$$\begin{aligned} \iiint_Q f(w, x, y, z) dw dx dy dz &\leq \oint_{\partial Q} f' \left(\max \left\{ \frac{\|w\|}{|w^2 + x^2|}, \frac{\|z\|}{|y^2 + z^2|}, \frac{\|w \oplus z\|}{\|x \oplus y\|} \right\} \right) \\ &\approx \bigcup_{Q \in \tilde{Q}} \left[f^* \left(\frac{\int Q(t)}{\sqrt{1 - t^2}} \right) \right]_{t=\alpha}^{t=\vartheta} - (\Delta + v - v)^3 \end{aligned} \quad (1)$$

For x in the open interval $] -1, 1[$ the infinite sum in Equation (2) is convergent; however, this does not hold throughout the closed interval $[-1, 1]$.

$$(1 - x)^{-k} = 1 + \sum_{j=1}^{\infty} (-1)^j \left\{ \begin{matrix} k \\ j \end{matrix} \right\} x^j \quad \text{for } k \in \mathbb{N}; k \neq 0. \quad (2)$$

12-18-fig

Unicode engines

Figure 12.18: Sample page typeset with Cambria text and math fonts

*Cambria math
support with
Unicode engines*

Cambria is a font family commissioned by Microsoft. It is one of the two commercial font families described in this book, because of its excellent math support and because of the fact that, despite its commercial nature, it is available to most users because it is shipped as part of the Windows operating system and several office products on different platforms. The sample shown in Figure 12.18 was produced with the following setup:

```
\usepackage{fontspec}      \setmainfont{Cambria}
\usepackage{unicode-math}  \setmathfont{Cambria Math}
```

Cambria math works well with many other transitional font families that do not have dedicated math support.

*Bitstream Charter
math support*

The Bitstream Charter fonts are best accessed through the XCharter package by Michael Sharpe, and matching math support is provided by the same author as part of his newtxmath package. For the sample in Figure 12.19 on the opposite page we used both, each with a number of options. The text fonts are slightly scaled down and use oldstyle figures, and we have slightly increased leading with `\linespread`.

For the math we scale the fonts slightly up, request an alternative to Charter's normal italic y, and use upright integrals and one of the alternative blackboard bold alphabets offered by the newtxmath package. This makes the setup look as follows:

```
\usepackage[scaled=.98,osf]{XCharter}    \linespread{1.04}
\usepackage[charter,scaled=1.05,alty,upint,vvarbb]{newtxmath}
```

Mathematical typesetting with Bitstream Charter

First some large operators both in text: $\iiint_Q f(x, y, z) dx dy dz$ and $\prod_{y \in \Gamma_{\tilde{C}}} \partial(\tilde{X}_y)$; and also on display:

$$\begin{aligned} \iiint_Q f(w, x, y, z) dw dx dy dz &\leq \oint_{\partial Q} f' \left(\max \left\{ \frac{\|w\|}{|w^2 + x^2|}; \frac{\|z\|}{|y^2 + z^2|}; \frac{\|w \oplus z\|}{\|x \oplus y\|} \right\} \right) \\ &\approx \bigcup_{Q \in \bar{Q}} \left[f^* \left(\frac{f(Q(t))}{\sqrt{1-t^2}} \right) \right]_{t=\alpha}^{t=\beta} - (\Delta + \nu - \nu)^3 \end{aligned} \quad (1)$$

For x in the open interval $] -1, 1[$ the infinite sum in Equation (2) is convergent; however, this does not hold throughout the closed interval $[-1, 1]$.

$$(1-x)^{-k} = 1 + \sum_{j=1}^{\infty} (-1)^j \binom{k}{j} x^j \quad \text{for } k \in \mathbb{N}; k \neq 0. \quad (2)$$

12-19-fig

Figure 12.19: Sample page typeset with XCharter text + math fonts

New Century Schoolbook has two notably different sets of matching math fonts. [New Century Schoolbook math support](#) Figure 12.20 on the next page shows the version by Michael Sharpe, generated with the following setup: `\usepackage{tgschola} \usepackage[ncf]{newtxmath}`. The newtxmath package can also be used with Unicode engines. However, you need to load the text font through fontspec, as shown below:

The second setup, exhibited in Figure 12.21, is again a work of the T_EX Gyre foundry; this is how the sample was produced:

```
\usepackage{fontspec}      \setmainfont{TeX Gyre Schola}
\usepackage{unicode-math}  \setmathfont{TeX Gyre Schola Math}
\setmathfont{KpMath}[range="2AB7,Scale=1.2] % difficult to find a good match
```

Page 277 shows examples of Libertine (Libertinus) by Philipp H. Poll and the math [Libertinus math support](#) support available for it. Figure 12.22 exhibits the math fonts by Michael Sharpe; we used the following setup to produce it:

```
\usepackage{libertinus} \usepackage[libertine,upint]{newtxmath}
```

There is also an OpenType font to accompany Libertinus designed by Khaled Hosny. This time we used the New Computer Modern Book font (which is slightly bold) and scaled it down by 10% to replace the missing glyphs.

```
\usepackage{fontspec}      \setmainfont{Libertinus Serif}
\usepackage{unicode-math}  \setmathfont{Libertinus Math}
\setmathfont{NewCMMath-Book}[range={"22D0","2AB7"},Scale=.9]
```

New Century Schoolbook text & math

First some large operators both in text: $\iiint_Q f(x, y, z) dx dy dz$ and $\prod_{\gamma \in \Gamma_{\tilde{C}}} \partial(\tilde{X}_{\gamma})$; and also on display:

$$\begin{aligned} \iiint_Q f(w, x, y, z) dw dx dy dz &\leq \oint_{\partial Q} f' \left(\max \left\{ \frac{\|w\|}{|w^2 + x^2|}, \frac{\|z\|}{|y^2 + z^2|}, \frac{\|w \oplus z\|}{\|x \oplus y\|} \right\} \right) \\ &\lesssim \bigcup_{Q \in \tilde{Q}} \left[f^* \left(\frac{f(Q(t))}{\sqrt{1-t^2}} \right) \right]_{t=\alpha}^{t=\theta} - (\Delta + \nu - \nu)^3 \end{aligned} \quad (1)$$

$$(1 - x)^{-k} = 1 + \sum_{j=1}^{\infty} (-1)^j \left\{ \begin{matrix} k \\ j \end{matrix} \right\} x^j \quad \text{for } k \in \mathbb{N}; k \neq 0. \quad (2)$$

12-24-fig

Figure 12.24: Sample page typeset with Lucida Bright text + Lucida Math fonts

Lucida Bright
math support

Three examples of Lucida Bright and Lucida New Math fonts are exhibited on this double spread. This set of commercial text and math fonts has been designed by Charles Bigelow and Kris Holmes and can be obtained from the T_EX Users Group at a reduced price for members. The font bundle covers all standard mathematical symbols including AMS additions. It can be used with all engines, but there are some differences in scope and design of individual glyphs between Type 1 and OpenType fonts.

As you will notice, the formulas run very wide, which enhances legibility at the cost of space. In this book the body font is Lucida Bright; however, for the examples we usually used Computer Modern to make them come out as in standard L^AT_EX.

In pdfT_EX, all that you need to do to set text and math in Lucida Bright is to load the package `lucidabr` (with options `expert` and `T1`)—this is what we did for Figure 12.24. For ways to use only some of its text fonts, see Section 10.2.10 on page 21. By default, `lucidabr` scales the fonts down, and if you use the OpenType versions directly, you probably want to do that too. So here is the setup for Figure 12.25:

```
\usepackage{fontspec} \setmainfont{Lucida Bright OT}[Scale=.95]
\usepackage{unicode-math}\setmathfont{Lucida Bright Math OT}[Scale=.95]
```

The Lucida families also contain a full demibold series, albeit only in OpenType format. These are shown for comparison in Figure 12.26. However, the demibold faces are incomplete, and again we had to substitute two characters—can you spot them?

```
\usepackage{fontspec}\setmainfont{Lucida Bright OT Demibold}[Scale=.95]
\usepackage{unicode-math}
\setmathfont{Lucida Bright Math OT Demibold}[Scale=.95]
\setmathfont{Lucida Bright Math OT}[range={"2A04,"2A0C"},Scale=.95]
```

Mathematical typesetting with Lucida Bright

First some large operators both in text: $\iiint f(x, y, z) dx dy dz$ and $\prod_{y \in \Gamma_c} \partial(\tilde{X}_y)$; and also on display:

Mathematical typesetting with Times (TX)

First some large operators both in text: $\iiint_Q f(x, y, z) dx dy dz$ and $\prod_{\gamma \in \Gamma_{\tilde{c}}} \partial(\tilde{X}_{\gamma})$; and also on display:

$$\begin{aligned} \iiint_Q f(w, x, y, z) dw dx dy dz &\leq \oint_{\partial Q} f' \left(\max \left\{ \frac{\|w\|}{|w^2 + x^2|}, \frac{\|z\|}{|y^2 + z^2|}, \frac{\|w \oplus z\|}{\|x \oplus y\|} \right\} \right) \\ &\approx \bigcup_{Q \in \tilde{Q}} \left[f^* \left(\frac{\int Q(t)}{\sqrt{1-t^2}} \right) \right]_{t=\alpha}^{t=\beta} - (\Delta + \nu - \nu)^3 \end{aligned} \quad (1)$$

For x in the open interval $] -1, 1[$ the infinite sum in Equation (2) is convergent; however, this does not hold throughout the closed interval $[-1, 1]$.

$$(1-x)^{-k} = 1 + \sum_{j=1}^{\infty} (-1)^j \begin{Bmatrix} k \\ j \end{Bmatrix} x^j \quad \text{for } k \in \mathbb{N}; k \neq 0. \quad (2)$$

12-27-fig

Figure 12.27: Sample page typeset with Times text (Termes) + TX math fonts

Times Roman math support

With Times Roman being one of the predominant fonts in use today, several solutions have been developed to provide support for it. This page spread and the next show five math font setups for use with Times Roman or a similar design as a body font. Figure 12.27 exhibits the TX fonts reworked by Michael Sharpe; see also Section 12.3.4 on page 243. The setup is as follows:

```
\usepackage{newtxtext} \usepackage[upint,subscriptcorrection]{newtxmath}
```

In Figure 12.28 the T_EX Gyre foundry solution is presented. One can argue that the j is set too tight. Here is the setup:

```
\usepackage{fontspec} \setmainfont{TeX Gyre Termes}
\usepackage{unicode-math} \setmathfont{TeX Gyre Termes Math}
\setmathfont{KpMath}[range="2AB7] % ok without scaling this time
```

Figure 12.29 shows fonts by Khaled Hosny based on STIX version 1 with smaller running length compared to STIX 2. All fonts based on STIX implement the full range of mathematical symbols including boldface variants, so no substitutions are needed.

```
\usepackage{fontspec} \setmainfont{XITS}
\usepackage{unicode-math} \setmathfont{XITS Math}
```

In Figure 12.30 on page 282 we have Michael Sharpe's setup for the STIX 2 fonts:

```
\usepackage[p,osf]{stickstootext} \usepackage[stix2,vvarbb]{newtxmath}
```

and Figure 12.31 shows the OpenType version of the fonts:

```
\usepackage{fontspec} \setmainfont{STIX Two Text}
\usepackage{unicode-math} \setmathfont{STIX Two Math Regular}
```

Mathematical typesetting with Termes

First some large operators both in text: $\iiint_{\mathcal{Q}} f(x, y, z) dx dy dz$ and $\prod_{\gamma \in \Gamma_{\tilde{C}}} \partial(\tilde{X}_{\gamma})$; and also on display:

$$(1-x)^{-k} = 1 + \sum_{j=1}^{\infty} (-1)^j \begin{Bmatrix} k \\ j \end{Bmatrix} x^j \quad \text{for } k \in \mathbb{N}; k \neq 0. \quad (2)$$

12-32-fig

Figure 12.32: Sample page typeset with Erewhon text + math fonts

Adobe Utopia, originally designed by Robert Slimbach, due to its open source license, has been extended by several people; see Section 10.5.23 on page 58. Math support for these fonts, as often, is available through Michael Sharpe's `newtxmath` package. It works equally well with the different versions of Utopia, e.g., Heuristica or Linguistics Pro. For Figure 12.32 we have used the following setup deploying Erewhon as the text font:

Utopia math support

```
\usepackage[osf]{erewhon}
\usepackage[utopia,vvarbb]{newtxmath}
```

If you want to use the math setup with other fonts, you may need to scale the text fonts a bit down or the math fonts up to get a perfect fit, e.g., for Heuristica:

```
\usepackage[osf,scaled=.92]{heuristica}
\usepackage[utopia,vvarbb]{newtxmath}
```

There is also the Fourier-GUTenberg bundle by Michel Bovani, which is also based on Adobe Utopia. It sets up both text and math fonts and is intended as a self-contained solution (automatically loading `amsmath` and other packages); in particular it offers “french-style” mathematics if loaded with the option `upright`, e.g.,

```
\usepackage[upright]{fourier}
```

12.5.3 Didone serif fonts with math support

*Computer Modern —
L^AT_EX's math default*

The majority of L^AT_EX documents are typeset using Didone fonts simply because L^AT_EX's standard fonts, Computer Modern, are Didone designs and because not so long ago these were the only fonts that could be used, if decent math support was needed — the current chapter shows that those days are history.

Figure 12.33 shows our example page using L^AT_EX's default setup when using pdfL^AT_EX. This is a repeat of Figure 12.1 from the beginning of the section to make it easier to compare it to other fonts in this section.

Unicode engines

When you use a Unicode engine without loading any math support package, then L^AT_EX keeps the math setup (i.e., Computer Modern), but it changes the text fonts to Latin Modern.

*Latin Modern
math support*

To use Latin Modern Math, designed by Bogusław Jackowski and Janusz Marian Nowacki (1951–2020), in pdfL^AT_EX, the following setup is sufficient:

```
\usepackage{lmodern}
```

The result is shown in Figure 12.34 (and is, not surprisingly, very similar to Computer Modern). Figure 12.35 then exhibits the OpenType fonts of LM:

```
\usepackage{fontspec} \setmainfont{Latin Modern Roman}
\usepackage{unicode-math} \setmathfont{Latin Modern Math}
\setmathfont{NewCMMath-Regular}[range="2AB7]
```

Mathematical typesetting with Computer Modern

First some large operators both in text: $\iiint_{\mathbb{Q}} f(x, y, z) dx dy dz$ and $\prod_{\gamma \in \Gamma_{\tilde{C}}} \partial(\tilde{X}_{\gamma})$; and also on display:

$$\begin{aligned} \iiint_{\mathbb{Q}} f(w, x, y, z) dw dx dy dz &\leq \oint_{\partial \mathbb{Q}} f' \left(\max \left\{ \frac{\|w\|}{|w^2 + x^2|}; \frac{\|z\|}{|y^2 + z^2|}; \frac{\|w \oplus z\|}{\|x \oplus y\|} \right\} \right) \\ &\approx \bigcup_{\mathbb{Q} \in \mathbb{Q}} \left[f^* \left(\frac{\int \mathbb{Q}(t)}{\sqrt{1-t^2}} \right) \right]_{t=\alpha}^{t=\vartheta} - (\Delta + \nu - v)^3 \end{aligned} \quad (1)$$

For x in the open interval $] -1, 1[$ the infinite sum in Equation (2) is convergent; however, this does not hold throughout the closed interval $[-1, 1]$.

$$(1-x)^{-k} = 1 + \sum_{j=1}^{\infty} (-1)^j \left\{ \begin{matrix} k \\ j \end{matrix} \right\} x^j \quad \text{for } k \in \mathbb{N}; k \neq 0. \quad (2)$$

$$(1 - x)^{-k} = 1 + \sum_{j=1}^{\infty} (-1)^j \left\{ \begin{matrix} k \\ j \end{matrix} \right\} x^j \quad \text{for } k \in \mathbb{N}; k \neq 0. \quad (2)$$

12-38-fig

Figure 12.38: Sample page typeset with Noto text + math fonts

The New Computer Modern OpenType family by Antonis Tzolomitis is the new kid on the block when it comes to designs that are based on or mimic Donald Knuth's Computer Modern family. Antonis is working very hard on making his family usable across various disciplines by adding more and more glyphs to support various scripts and languages. At the time of writing the Roman font contained 3171 glyphs and the math support font a whopping 6938 and I would not be surprised if there are many more by the time you hold this book in your hands — check it by using `unicodefont.tex`, but make sure to set `range-end` to `FFFFF` to get to all characters.

Math setup for New Computer Modern

Figure 12.36 on the facing page has been produced by this input:

```
\usepackage{fontspec}      \setmainfont{NewCM10-Regular}
\usepackage{unicode-math}  \setmathfont{NewCMMath-Regular}
```

The slightly darker Book version in Figure 12.37 was generated with:

```
\usepackage{fontspec}      \setmainfont{NewCM10-Book}
\usepackage{unicode-math}  \setmathfont{NewCMMath-Book}
```

The last Didone family we exhibit in Figure 12.38 is Noto Serif. The math support is again courtesy of Michael Sharpe, this time through his `notomath` package; see Section 12.3.7 on page 252. We used the following setup:

Not Serif math support

```
\usepackage[vvarbb,upint]{notomath}
```

12.5.4 Slab serif fonts with math support

*Math support for
Concrete Roman*

The Concrete Roman text fonts were designed by Donald Knuth, and matching math fonts were designed by Ulrik Vieth; see Section 12.3.1. They are shown in Figure 12.39, which was produced by adding `\usepackage[boldsans]{ccfonts}` to the preamble of the sample document.

Figure 12.40 combines Concrete Roman with Euler Math, designed by Hermann Zapf (1918–2015). This combination was produced with

```
\usepackage{ccfonts} \usepackage[euler-digits]{eulervm}
```

See also Section 12.3.3. You probably want to design different headings: because the Concrete fonts have no bold series, the heading in the example shows a larger size of the medium series through substitution.

*Math support for
DejaVu*

The other Slab serif family with math support is DejaVu, again provided by the T_EX Gyre foundry. The design size is rather large, so we scaled everything down for Figure 12.41. Given that the font is fairly black we used a bold symbol from the Kp math font to supply the missing glyph. Not perfect, but ...

```
\usepackage{fontspec} \setmainfont{DejaVu Serif}[Scale=.9]
\usepackage{unicode-math} \setmathfont{TeX Gyre DejaVu Math}[Scale=.95]
\setmathfont{KpMath-Bold}[range="2AB7,Scale=.97] % more or less ok
```

Mathematical typesetting with Concrete

First some large operators both in text: $\iiint_{\mathbb{Q}} f(x, y, z) dx dy dz$ and $\prod_{\gamma \in \Gamma_{\tilde{c}}} \partial(\tilde{X}_{\gamma})$; and also on display:

$$\iiint_{\mathbb{Q}} f(w, x, y, z) dw dx dy dz \leq \oint_{\partial Q} f' \left(\max \left\{ \frac{\|w\|}{|w^2 + x^2|}, \frac{\|z\|}{|y^2 + z^2|}, \frac{\|w \oplus z\|}{\|x \oplus y\|} \right\} \right) \\ \approx \bigcup_{Q \in \tilde{Q}} \left[f^* \left(\frac{\int \mathbb{Q}(t)}{\sqrt{1 - t^2}} \right) \right]_{t=\alpha}^{t=\vartheta} - (\Delta + \nu - v)^3 \quad (1)$$

For x in the open interval $] -1, 1[$ the infinite sum in Equation (2) is convergent; however, this does not hold throughout the closed interval $[-1, 1]$.

$$(1 - x)^{-k} = 1 + \sum_{j=1}^{\infty} (-1)^j \left\{ \begin{matrix} k \\ j \end{matrix} \right\} x^j \quad \text{for } k \in \mathbb{N}; k \neq 0. \quad (2)$$

Mathematical typesetting with DejaVu

First some large operators both in text: $\iiint_{\tilde{Q}} f(x, y, z) \, dx \, dy \, dz$ and $\prod_{\nu \in \Gamma_{\tilde{C}}} \partial(\tilde{X}_{\nu})$; and also on display:

$$\begin{aligned} \iiint_{\tilde{Q}} f(w, x, y, z) \, dw \, dx \, dy \, dz &\leq \oint_{\partial Q} f' \left(\max \left\{ \frac{\|w\|}{|w^2 + x^2|}; \frac{\|z\|}{|y^2 + z^2|}; \frac{\|w \oplus z\|}{\|x \oplus y\|} \right\} \right) \\ &\approx \biguplus_{Q \in \tilde{Q}} \left[f^* \left(\frac{\mathbb{Q}(t)}{\sqrt{1-t^2}} \right) \right]_{t=\alpha}^{t=\vartheta} - (\Delta + \nu - \nu)^3 \end{aligned} \quad (1)$$

For x in the open interval $] -1, 1[$ the infinite sum in Equation (2) is convergent; however, this does not hold throughout the closed interval $[-1, 1]$.

$$(1-x)^{-k} = 1 + \sum_{j=1}^{\infty} (-1)^j \left\{ \begin{matrix} k \\ j \end{matrix} \right\} x^j \quad \text{for } k \in \mathbb{N}; k \neq 0. \quad (2)$$

12-41-fig

Unicode engines

Figure 12.41: Sample page typeset with DejaVu + DejaVu Math fonts

12.5.5 Sans serif fonts with math support

*Math support for
Computer Modern
Bright*

Figure 12.42 shows the Computer Modern Bright set of fonts (designed by Walter Schmidt (1960–2021)), which is based on the Computer Modern font design. The solution offers the full range of math symbols in normal and bold weights and is activated by loading the `cmbright` package; see Section 12.3.2.

*Math support for
Fira Sans*

Xiangdong Zeng developed a Fira Math font based on FiraSans and FiraGo. As with many of the OpenType Math fonts there are some glyphs missing, and finding a suitable substitute font proved to be difficult. In Figure 12.43, I used bold Kp Math scaled down by 30% for `\precapprox` and 10% for `\biguplus` and `\Subset`.

```
\usepackage{fontspec}      \setmainfont{Fira Sans}
\usepackage{unicode-math}   \setmathfont{Fira Math}
\setmathfont{KpMath-Bold}[range="2AB7,Scale=.75] % not a good match
\setmathfont{KpMath-Bold}[range={"2A04","22D0"},Scale=.9]
```

This clearly shows limitations of the approach: `\precapprox` is still too wide and at the same time too thin. Thus, if you cannot find a suitable substitute and you need the symbols, it is probably better to use a different font setup.

*Math support for
GFS Neo-Hellenic*

The GFS Neo-Hellenic, designed in 1927 by Victor Scholderer (see Section 10.8.14 on page 75), has a matching OpenType math font, which was commissioned in 2018, but there is no support for math in pdf_TE_X. To use the OpenType fonts, all you have to do is to load a support package, which does the necessary setup for you, i.e.,

```
\usepackage{gfsneohellenicot}
```

Mathematical typesetting with CM Bright

First some large operators both in text: $\iiint_{\mathbb{Q}} f(x, y, z) dx dy dz$ and $\prod_{\gamma \in \Gamma_c} \partial(\tilde{X}_\gamma)$; and also on display:

$$\iiint_{\mathbb{Q}} f(w, x, y, z) dw dx dy dz \leq \oint_{\partial Q} f' \left(\max \left\{ \frac{\|w\|}{|w^2 + x^2|}; \frac{\|z\|}{|y^2 + z^2|}; \frac{\|w \oplus z\|}{\|x \oplus y\|} \right\} \right) \\ \approx \biguplus_{\mathbb{Q} \in \bar{\mathbb{Q}}} \left[f^* \left(\frac{\int \mathbb{Q}(t)}{\sqrt{1 - t^2}} \right) \right]_{t=\alpha}^{t=\emptyset} - (\Delta + \nu - \nu)^3 \quad (1)$$

For x in the open interval $] -1, 1[$ the infinite sum in Equation (2) is convergent; however, this does not hold throughout the closed interval $[-1, 1]$.

$$(1 - x)^{-k} = 1 + \sum_{j=1}^{\infty} (-1)^j \left\{ \begin{matrix} k \\ j \end{matrix} \right\} x^j \quad \text{for } k \in \mathbb{N}; k \neq 0. \quad (2)$$

12-47-fig

Figure 12.47: Sample page typeset with Kp Sans text + math fonts

The Iwona fonts, designed by Janusz Marian Nowacki (1951–2020), are provided in several font series (see Section 10.8.18 on page 77), and for all them there is matching math support if you add the option `math` when loading the `iwona` support package. For example, Figure 12.46 used

Math support for Iwona

```
\usepackage[math,light,condensed]{iwona}
```

to produce the light condensed setup. Unfortunately, all fonts miss the smallest glyph of the extensible delimiters `\lVert` and `\rVert` (normally slot "6B in the `symbols` math font), most likely a simple oversight by the author. Thus, to make our sample documents work, we also had to provide it from a different source and update the delimiter declarations as follows:

```
\DeclareSymbolFont{symbols2}{OMS}{cmsy}{m}{n}
\SetSymbolFont{symbols2}{bold}{OMS}{cmsy}{b}{n}
\DeclareMathDelimiter{\lVert}{\mathopen}{symbols2}{"6B}{largesymbols}{"0D}
\DeclareMathDelimiter{\rVert}{\mathclose}{symbols2}{"6B}{largesymbols}{"0D}
```

For details on the above declarations see Section 9.8.5 on page 749.

Using Kp Sans as the body font to produce Figure 12.47 is as simple as loading the package `kpfonts` with the option `sfmath`, or, if you want to use OpenType fonts in Unicode engines, the package `kpfonts-otf`. There are many more package options available to adjust the setup; see Section 10.2.8 on page 17 for more details.

Math support for Kp Sans

Mathematical typesetting with Kurier

First some large operators both in text: $\iiint_Q f(x, y, z) dx dy dz$ and $\prod_{\gamma \in \Gamma_{\tilde{c}}} \partial(\tilde{X}_{\gamma})$; and also on display:

$$\iiint_Q f(w, x, y, z) dw dx dy dz \leq \oint_{\partial Q} f' \left(\max \left\{ \frac{\|w\|}{|w^2 + x^2|}; \frac{\|z\|}{|y^2 + z^2|}; \frac{\|w \oplus z\|}{\|x \oplus y\|} \right\} \right) \\ \approx \bigcup_{Q \in \tilde{Q}} \left[f^* \left(\frac{\int Q(t)}{\sqrt{1 - t^2}} \right) \right]_{t=\alpha}^{t=\vartheta} - (\Delta + \nu - \nu)^3 \quad (1)$$

For x in the open interval $] -1, 1[$ the infinite sum in Equation (2) is convergent; however, this does not hold throughout the closed interval $[-1, 1]$.

$$(1 - x)^{-k} = 1 + \sum_{j=1}^{\infty} (-1)^j \left\{ \begin{matrix} k \\ j \end{matrix} \right\} x^j \quad \text{for } k \in \mathbb{N}; k \neq 0. \quad (2)$$

$$(1-x)^{-k} = 1 + \sum_{j=1}^{\infty} (-1)^j \left\{ \begin{matrix} k \\ j \end{matrix} \right\} x^j \quad \text{for } k \in \mathbb{N}; k \neq 0. \quad (2)$$

12-50-fig

Figure 12.50: Sample page typeset with Noto Sans text + math fonts

Just like his Iwona fonts, Kurier by Janusz Marian Nowacki (1951–2020) offers several different series values, all with full math support. The options of the support package `kurier` are also the same (but unfortunately also the lapse with respect to `\lVert` and `\rVert`). Thus, the setup for Figures 12.48 and 12.49 looks like this:

*Math support for
Kurier*

```
\usepackage[math]{kurier}
\DeclareSymbolFont{symbols2}{OMS}{cmsy}{m}{n}
\SetSymbolFont{symbols2}{bold}{OMS}{cmsy}{b}{n}
\DeclareMathDelimiter{\lVert}{\mathopen}{symbols2}{"06B}{\largesymbols}{"0D}
\DeclareMathDelimiter{\rVert}{\mathclose}{symbols2}{"6B}{\largesymbols}{"0D}
```

except that in the second example we additionally added the option `light`.

Matching math fonts for Noto Sans are provided by Michael Sharpe with a dedicated support package (see Section 12.3.7). The setup we used in Figure 12.50 was the following:

*Math support for
Noto Sans*

```
\usepackage[vvarbb,upint,sfdefault]{notomath}
```

12.5.6 Historical fonts with math support

Out of the historical fonts covered in this book only Antykwa Toruńska comes with dedicated math fonts. Figures 12.51 and 12.52 on the next page have been both set up using the package `anttor`: the first with option `math` and the second additionally with options `light` and `condensed`.

CHAPTER 13

Localizing Documents

13.1 \TeX and non-English languages	297
13.2 The babel user interface.	301
13.3 User commands provided by language options	308
13.4 Support for Cyrillic and Greek	324
13.5 Complex scripts	330
13.6 Tailoring babel	332
13.7 Other approaches	341

This chapter starts with a short introduction to the technical problems that must be solved if you want to use \LaTeX with a non-English language. Most of the remaining part of the chapter discusses the babel system, which provides a convenient way to generate documents in different languages. We look in particular at how we can typeset documents in French, Russian, and Greek, as the typesetting of those languages illustrates various aspects of the things one has to deal with in a non-English environment. We also say a few words about how to handle other languages, such as Arabic, Japanese, or Hindi, which are written with the so-called “complex scripts”. Section 13.6 explains how to tailor the language styles to fit your needs in some common cases.

13.1 \TeX and non-English languages

Due to its popularity in the academic world, \TeX spread rapidly throughout the world and is now used not only with the languages based on the Latin alphabet, but also with languages using non-Latin alphabetic scripts, such as Russian, Greek, Arabic, Persian, Hebrew, Thai, Vietnamese, Malayalam, or Marathi. Implementations also exist for Chinese and Japanese (which use Kanji-based ideographic scripts) and Korean (which uses syllable blocks).

With the introduction of 8-bit T_EX and METAFONT, which were officially released by Donald Knuth in March 1990, the problems of multilingual support could be more easily addressed for the first time. Nevertheless, by themselves, these versions did not solve all the problems associated with providing a convenient environment for using L^AT_EX with multiple and/or non-English languages, which were eventually addressed with the advent of Unicode engines like X_YL^AT_EX and LuaT_EX.

To achieve this goal, T_EX and its companion programs should be made truly international, and the following points should be addressed:

1. Adjust all programs to the particular language(s):
 - Handle properly fonts containing national symbols, which includes setting up the so-called Unicode fonts where necessary and appropriate [67],
 - Define line breaking and justification rules, which in Western languages means generating patterns for the hyphenation algorithm,
 - Support typesetting in different directions.
2. Provide a translation for the language-dependent strings, create national layouts for the standard documents, and provide T_EX or Lua code to treat the language-dependent typesetting rules automatically [130].
3. Support processing of multilingual documents (more than one language in the same document) and work in international environments (one language per document, but a choice between several possibilities). For instance, the sorting of indexes and bibliographic references should be performed in accordance with a given language's alphabet and collating sequence; see the discussion on `upmendex` in Section 14.3 and `biber` in Section 15.2.2.

At the same time, you should be able to conveniently edit, view, and print your documents using any given character set, and L^AT_EX should be able to successfully process files created in this way. Encoding problems were ultimately solved with Unicode, which can encode not only the alphabetic languages but also ideographic scripts like Chinese or Japanese.

L^AT_EX uses by default the encoding known as UTF-8, which has been universally adopted in the computing and publishing worlds. There still exist other character encoding schemes, but their use is declining, because with them it is difficult for documents to be reproducible in different environments, issues of standardization become important, and it is necessary to know the encoding in which a document was produced if not UTF-8. For such legacy encodings L^AT_EX offers the `inputenc` package, described in Section 9.9.3 on page 758, but it is recommended to avoid it and use the default (UTF-8) for new documents.¹

To adapt L^AT_EX to different languages, several approaches have been followed. The first to appear was to use dedicated packages, which very often were incompatible,

¹A few packages, including some `babel` languages, have not been yet updated for the current default encoding and may display a warning like “No input encoding specified” or similar. It can be usually ignored.

thus making a multilingual document almost impossible. A second step was the introduction of `babel`, which eased the standardization and development of T_EX-related software adapted to different languages. The aim was to produce for each language or group of languages a package that would facilitate typesetting, with details about fonts, input conventions, hyphenation patterns, a `ℒTEX` option file compatible with the `babel` concept (see Section 13.1.3), possibly a preprocessor, and, of course, documentation in English and the target language. Still, because each language takes its own solutions, interoperation remains problematic, and a new approach, based on a core providing the basic behavior with descriptive `.ini` files, is being developed at the time of this writing, although it has reached a very advanced stage.

In some languages, particularly East Asian ones, there is another approach, namely, extending the T_EX program to suit the needs of a particular family of languages. For example, `upTEX` adds features for vertical writing and deals with other facets of typesetting Japanese.

Besides `XYTEX` and `LuaTEX`, there have been other extensions to the T_EX program attempting to improve the T_EX multilingual support, like `mlTEX`, `EncTEX`, or `Omega`. The latter, by Yannis Haralambous and John Plaice, incorporated a sophisticated bidi algorithm, which has become part of `LuaTEX`, and provided a mechanism to perform text transformations, which has inspired what in `babel` are called *transforms* (transliterations is an example).

13.1.1 Language-related aspects of typesetting

When thinking about supporting typesetting documents in languages other than English, a number of aspects that need to be dealt with come to mind.

First and foremost is the fact that other languages have different rules for line breaking, something that T_EX accommodates in Western languages through its support for multiple hyphenation patterns. In some languages, however, certain letter combinations change when they appear at a hyphenation point.

Unicode engines

T_EX does not support this capability “out of the box”, but `LuaTEX` can be extended to apply nonstandard hyphenation rules — a feature exploited by `babel` when using this engine. Scripts like Thai, Japanese, or Amharic follow some specific rules, which require `XYTEX` and `LuaTEX`.

Some languages need different sets of characters to be properly typeset. This issue can vary from the need for additional “accented letters” (as is the case with many European languages) to the need for a completely different alphabet (as is the case with languages using the Cyrillic or Greek alphabet).

Unicode engines

When non-European languages need to be supported, the typesetting direction might be different as well (such as right to left for Arabic and Hebrew texts), or so many characters might be needed (as is the case with the Kanji script, for instance) that traditional T_EX’s standard mechanisms cannot deal with them — in that case `XYTEX` or `LuaTEX` is required.

A more “subtle” problem turns up when we look at the standard document classes that each \LaTeX distribution supplies, because they were designed for the Anglo-American situation. A specific example where this preference interferes with supporting other languages is the start of a chapter. For some languages it is not enough to just translate the word “Chapter”; the order of the word and the denomination of the chapter needs to be changed as well, solely on the basis of grammatical rules. Where the English reader expects to see “Chapter 1”, the Hungarian reader expects to see “1. fejezet”.

13.1.2 Culture-related aspects of typesetting

An even thornier problem when faced with the need to support typesetting of many languages is the fact that typesetting rules differ, even between countries that use the same language. For instance, hyphenation rules differ between British English and American English. Translations of English words might vary between countries, just as they do for the German spoken in Germany and the German spoken (and written) in Austria.

Typographic rules may differ between countries, too. No worldwide standard tells us how nested lists should be typeset; on the contrary, their appearance may differ for different languages or countries or even printing houses. With these aspects we enter the somewhat fuzzy area comprising the boundary between the language aspects of typesetting and the cultural aspects of typesetting. It is not clear where that boundary lies. When implementing support for typesetting documents written in a specific language, this difference needs to be taken into account. The language-related aspects can be supported on a general level, but the cultural aspects are more often than not better (or more easily) handled by creating specific document classes.

13.1.3 `babel` — \LaTeX speaks multiple languages

The \LaTeX distribution contains a few standard document classes that are used by most users. These classes (article, report, book, and letter) have a certain American look and feel, which not everyone likes. Moreover, the language-dependent strings, such as “Chapter” and “Table of Contents” (see Table 13.2 on page 305 for a list of commands holding language-dependent strings), come out in English by default.

The `babel` package, originally developed by Johannes Braams [23] and now maintained and developed further by Javier Bezos [19], provides a set of options that allows the user to choose the language or language(s) in which the document is typeset. It has the following basic characteristics:

- Multiple languages can be used simultaneously.
- The list of hyphenation patterns to be loaded when the \LaTeX format is generated can be defined via an external file.
- Translations for the language-dependent strings and commands for facilitating text input are provided for more than 60 languages (a selection of them is listed in Table 13.1 on the facing page).

afrikaans	esperanto	italian	russian
albanian	estonian	kurmanji	samin
azerbaijani	finnish	latin	scottish
basque	french	latvian	serbian
belarusian	friulan	lithuanian	serbianc
bosnian	galician	lowersorbian	slovak
breton	german, ngerman,	macedonian	slovene
bulgarian	austrian,	malay	spanish
catalan	naustrian	magyar	swedish
croatian	greek,	norsk, nynorsk	turkish
czech	polutonikogreek	occitan	turkmen
danish	hebrew	polish	ukrainian
dutch	icelandic	portuguese,	uppersorbian
english, USenglish,	indonesian	brazilian	vietnamese
UKenglish,	interlingua	romanian	welsh
australian	irish	romansh	

Alternatives for a language typically differ in hyphenation rules, date handling, or language-dependent strings. The option `english` combines American hyphenation patterns with a British date format.

Table 13.1: Selective list of language options supported by the babel system

In the next section we describe the user interface of the babel system. We then discuss the additional commands for various languages and describe the support for typesetting languages using non-Latin alphabets. Finally, we discuss ways to tailor babel to your needs. Throughout the sections, examples illustrate the use of various languages supported by babel.

13.2 The babel user interface

Languages that you use in your document should be declared as options when loading the babel package. Alternatively, because the languages in which a document is written constitute a global characteristic of the document, the languages can be indicated as *global options* on the `\documentclass` command. This strategy makes them available to any package that changes behavior depending on the language settings of the document. Most languages are identified by their English names (see Table 13.1 for the recommended names in many languages), although there are a few exceptions. For example, the following declaration prepares for typesetting in the languages German (option `ngerman` for new orthography) and Italian (option `italian`):

```
\usepackage[ngerman,italian]{babel}
```

The last language appearing on the `\usepackage` command line becomes the default language used at the beginning of the document. In the above example, the language-dependent strings, the hyphenation patterns (if they were loaded for the given language when the \LaTeX format was generated; see the discussion on page 337), and possibly the interpretation of certain language-dependent commands (such as the date) will be for Italian from the beginning of the document up to the point where you choose a different language.

If one decides to make `ngerman` and `italian` global options, then other packages can also detect their presence. For example, the following code lets the package `varioref` (described in Section 2.4.1 on page 179) detect and use the options specified on the `\documentclass` command:

```
\documentclass[ngerman,italian]{article}
\usepackage{babel}
\usepackage{varioref}
```

If you use more than one language in your document and you want to define your own language-dependent strings for the `varioref` commands, you should use the methods described in Section 2.4.1.

Very often, a document is written entirely in a single language with a few words or phrases in other languages. In such a case and if the main font is appropriate for the latter, there is no need to declare those extra languages explicitly if all you need is to get them properly hyphenated, because they can be loaded by `babel` on the fly, with some basic features, when selected with one of the macros described in the following section.

13.2.1 Setting or getting the current language

Within a document it is possible to change the current language in several ways. For example, you can change all language-related settings including translations for strings like “Chapter”, the typesetting conventions, and the setup for shorthand commands. Alternatively, you can keep the translations unchanged but modify everything else (e.g., when typesetting short texts in a foreign language within the main text). Finally, you can change only the hyphenation rules.

The two basic commands are `\selectlanguage`, for large blocks of text like paragraphs, and `\foreignlanguage`, for changes inside paragraphs. These are the preferred ways to switch a language, but in some cases the environment versions can be useful.

<code>\selectlanguage{language}</code> <code>\begin{otherlanguage}{language}</code>

A change to all language-related settings is implemented via the `\selectlanguage` command. For instance, if you want to switch to German, you would use the command `\selectlanguage{german}`. The process is similar for switching to other languages. The `\selectlanguage` command calls the macros defined in the language definition file (see Section 13.6) and activates the special definitions for the

language in question. It also updates the setting of TeX's `\language` primitive used for hyphenation or, in the case of languages like Thai and Chinese with Xe_{La}TeX and Lua_{La}TeX, activates the line-breaking rules.

The environment `otherlanguage` provides the same functionality as the `\selectlanguage` declaration, except that the language change is local to the environment. The argument *language* is the language you want to switch to.

```
\foreignlanguage[key list]{language}{phrase}
\begin{otherlanguage*}[key list]{language}
```

The command `\foreignlanguage` typesets *phrase* according to the rules of *language*. It switches only the extra definitions and the line-breaking rules for the language, but not the names and dates, unless you specify captions or date in the *key list* argument. Its environment equivalent is `otherlanguage*`.

The expansion of fixed document element names depends on the language; e.g., in English we have “References” or “Chapter”.

Auf Deutsch ergibt sich „Literatur“ oder „Kapitel“.

Voici en français : « Références » ou « Chapitre ».

However, in short phrases “Références” does not change by default!

```
\usepackage[german,french,english]{babel}
\raggedright
```

```
The expansion of fixed document element names
depends on the language; e.g., in English
we have ‘‘\refname’’ or ‘‘\chaptername’’. \par
\selectlanguage{german} Auf Deutsch ergibt sich
’’\refname’’ oder ‘‘\chaptername’’. \par
\begin{otherlanguage}{french} Voici en français:
\og\refname\fg{} ou \og\chaptername\fg.
\par\foreignlanguage{english}{However, in short
phrases ‘‘\refname’’ does not change by default!}
\end{otherlanguage}
```

13-2-1

```
\begin{hyphenrules}{language}
```

Inside the environment `hyphenrules`, *only* the hyphenation rules are switched to those of the specified *language*; `\language` and all other settings remain unchanged. When no hyphenation rules for *language* are loaded into the format, the environment has no effect.

As a special application, this environment can be used to prevent hyphenation altogether, provided that in `language.dat` the “language” `nohyphenation` is defined (by loading `zerohyph.tex`, as explained in Section 13.6.2 on page 337). This is, actually, the only recommended use for this environment.

This text shows the effect of hyphenation.

This text shows the effect of hyphenation turned off.

```
\usepackage[english]{babel}
```

```
This text shows the effect of hyphenation.\par
\begin{hyphenrules}{nohyphenation}
This text shows the effect of hyphenation turned off.
\end{hyphenrules}
```

13-2-2

Note that this approach works even if the “language” `nohyphenation` is not specified as an option to the `babel` package.

If more than one language is used, it might be necessary to know which language is active at a specific point in the document. This can be checked with a call to `\iflanguage`.

```
\iflanguage{language}{true-clause}{false-clause}
```

The first argument in this syntax, *language*, is the name of a language, which is first checked to see whether it corresponds to a language declared to `babel`. If the *language* is known, the command compares its *hyphenation rules* with those for the current language. If they are the same, the commands specified in the *true-clause* are executed; otherwise, the commands specified in the third argument, *false-clause*, are executed.

The name of this macro is somewhat misleading, because it does not compare actual `babel` languages but the hyphenation patterns used, as the following example illustrates. If you need to check for the current language, you are better off resorting to the `iflang` package by Heiko Oberdiek.

The current language is `naustrian`, i.e., Austrian, and its hyphenation rules are the same as for German. English has different patterns.

```
\usepackage[english,ngerman,naustrian]{babel}
```

The current language is `\texttt{naustrian}`, i.e., Austrian, and its hyphenation rules `\iflanguage{ngerman}{are}{are not}` the same as for German. English has `\iflanguage{english}{the same}{different}` patterns.

13-2-3

```
\language
```

The control sequence `\language` contains the name of the current language.

```
\usepackage[german,french,english]{babel}
```

Language-dependent strings

Most document classes available in a \LaTeX installation define a number of commands that are used to store the various language-dependent strings. Table 13.2 on the facing page presents an overview of these commands, together with their default text strings.

13.2.2 Handling shorthands

A “shorthand” is a one- or two-character sequence, the first character of which introduces the shorthand and is called the “shorthand character”. For a two-character shorthand, the second character specifies the behavior of the shorthand. This mechanism

Table 13.2: Language-dependent strings in babel (English defaults)

was originally devised for authors who write in languages other than English, because it was sometimes awkward to type the input needed to produce the letters of their languages in the final document.

\TeX now understands UTF-8 input (which is its default since 2018); thus, most characters can be directly entered from the keyboard, which means that for many European languages shorthands are not as necessary as in the past. Given that they require a lot of extra processing, you can nowadays tell `babel` not to define them with the package option `shorthands=off`. However, they can be still useful in some cases:

- Several kinds of discretionaries and breaks can be inserted easily with `"-`, `"=`, and others.
- Shorthands such as `!` are used to insert the right amount of white space.
- In some languages, shorthands such as `"a` are defined to allow word hyphenation if the font encoding is OT1 (a better solution in most European languages is to use T1 instead, though).
- Finally, minority languages and some kinds of text can still require characters not easily available on the keyboards (and sometimes not even available as separated or precomposed Unicode characters).

The most important shorthands of these kinds are exhibited in later sections.

Babel knows about four shorthand levels — those defined by “the system”, “the language”, “the user”, and “the user for a specific language”. The purpose of this mechanism is to allow users to adapt easily its behavior to their needs. Shorthands can then act like a sort of customizable language-dependent markup.

Document-level commands for shorthands

This section describes the shorthand commands that can be used in the document and various aspects of the shorthand concept. Language-level or system-level shorthands are declared in language definition files; see Section 13.6 on page 332.

```
\usesshorthands*{char}
```

The command `\usesshorthands` initiates the definition of user-defined shorthand sequences. The argument *char* is the character that starts these shorthands.

Because languages may turn shorthands on and off, the starred variant makes sure user shorthands are always active.

```
\defineshorthand{charseq}{expansion}
```

The command `\defineshorthand` defines a shorthand. Its first argument, *charseq*, is a one- or two-character sequence; the second argument, *expansion*, is the code to which the shorthand should expand.

```
\languageshorthands{language}
```

The command `\languageshorthands` is used to switch between shorthands for the *language* specified as an argument. The *language* must have been declared to `babel` for the current document. When switching languages, the language definition files usually issue this command for the language in question. For example, the file `frenchb.ldf` contains the following command:

```
\languageshorthands{french}
```

Sometimes it is necessary to temporarily switch off the shorthand action of a given character because it needs to be used in a different way.

```
\shorthandon{chars}    \shorthandoff{chars}
```

The command `\shorthandoff` sets the `\catcode` for each of the characters in its argument *chars* to “other” (12). Conversely, the command `\shorthandon` sets the `\catcode` to “active” (13) for its argument *chars*. Both commands act only on “known” shorthand characters. If a character is not known to be a shorthand character, its category code is left unchanged.

For example, the language definition file for French (`frenchb.ldf`) makes the “double” punctuation characters “?”, “!”, “:”, and “;” active. One can eliminate this behavior by specifying each as an argument to a `\shorthandoff` command. This step is necessary with certain packages, where the same characters have a special meaning.

The next example loads the `xy` package, where the use of “;” and “?” as shorthand characters is turned off inside `xy`’s `xy` environment [55, Chapter 7], because these

characters have a functional meaning there.

	<code>\usepackage{xy}</code>
	<code>\usepackage[french]{babel}</code>
Voici un exemple avec <i>xypic</i> :	Voici un exemple avec <code>\emph{xypic}</code> :
	<code>\[\shorthandoff{;}]</code>
	<code>\begin{xy} (0,0)*{\bullet}, (0,0) ; (10,0),</code>
	<code>**\dir {-} ?>* \dir {>}, (12,0)*{x}, \end{xy}</code>
	<code>\]</code>
13-2-5 Quelle belle flèche !	Quelle belle flèche !

In the particular case of `tikz`, you can use `\usetikzlibrary{babel}` instead of `\shorthandoff` to overcome these issues for all `tikz` pictures of the document.

13.2.3 Language attributes

Sometimes the support for language-dependent typesetting needs to be tailored for different situations. In such a case it is possible to define attributes for the particular language. Two examples of the use of attributes can be found in the support for typesetting of Latin texts. When the attribute `usej` is selected, certain document element names are spelled differently (for example, “Junii” instead of “Iunni”). The attribute `withprosodicmarks` can be used when typesetting grammars, dictionaries, teaching texts, and the like, where prosodic marks are important for providing complete information on the words or the verses.

`\languageattribute{language}{langattrs}`

The command `\languageattribute` declares which attributes are to be used for a given language. It must be used in the preamble of the document following the command `\usepackage[...]{babel}` that loads the `babel` package. The command takes two arguments: *language* is the name of a language, and *langattrs* is a comma-separated list of attributes to be used for that language. The command checks whether the *language* is known in the current document and whether the attributes are known for this language.

For instance, `babel` has two variants for the Greek language: `monotoniko` (one-accent), the default, and `polutoniko` (multi-accent). To select the `polutoniko` variant, one must specify it in the document preamble, using the `\languageattribute` command. The following two examples illustrate the difference:

	<code>\usepackage[greek,english]{babel}</code>	<code>\usepackage{lmodern}</code>
13-2-6 The Greek word for ‘Index’ is Εὑρετήριο.	The Greek word for ‘Index’ is <code>\selectlanguage{greek}\indexname</code> .	

With the `polutoniko` attribute we get a different result:

	<code>\usepackage[greek,english]{babel}</code>	<code>\usepackage{lmodern}</code>
	<code>\languageattribute{greek}{polutoniko}</code>	
13-2-7 The Greek word for ‘Index’ is Εὐρετήριο.	The Greek word for ‘Index’ is <code>\selectlanguage{greek}\indexname</code> .	

Besides Greek, there are several language styles defining attributes, like Belarusian, Czech, Estonian, Japanese, and Latin, among others. For further information, refer to the corresponding manuals, which can be found on CTAN (<https://www.ctan.org/tex-archive/macros/latex/contrib/babel-contrib>).

13.2.4 BCP 47 tags

It has become customary in many environments to identify languages with the help of conventional labels. There are several sets of them, but the most popular by far are those defined following the Best Current Practice (BCP) 47, a standard published by the Internet Engineering Task Force (IETF) [164]. Languages are identified with two- or three-letter codes, which can be followed, in its most basic form, by a four-letter code for the script. Sometimes, a two-letter code for the region is added, too, like `de-AT`, which is the German language as spoken in Austria.

Requesting and selecting languages with the BCP 47 tags is usually cumbersome, and it is not the recommended practice, but they are often the preferred way to identify locales in documents generated by external tools, like bibliography managers. The `babel` package is able to select languages with them, if desired, and because the main document may not know which languages are required, the most basic settings can be loaded on the fly. Thus, a bibliographic reference with containing `\foreignlanguage{ru}{Some Russian title}` selects a Cyrillic font (which should be defined elsewhere) and the Russian hyphenation patterns, even if not explicitly declared as a class or package option.

This feature is primarily meant for special tasks, like the one just explained, and for this reason it must be activated explicitly, either by the user or by a package requiring it, in the following way:

```
\babeladjust{ autoloader.bcp47 = on,
               autoloader.bcp47.options = import }
```

`\babeladjust` is a multipurpose macro to configure the `babel` behavior (details on in can be found in the `babel` manual). In this case, it tells `babel` to allow BCP 47 tags in addition to language names and to import the data provided in a set of `.ini` files containing miscellaneous data for about 250 languages.

13.3 User commands provided by language options

This section gives a general overview of the features typically offered by the various language options. It includes translations of language-dependent strings and a survey of typical shorthands intended to ease language-specific document content or to solve language-specific typesetting requirements. Some language options define additional commands to produce special date formats or numbers in a certain style. Also discussed are layout modifications as undertaken for French as well as the interfaces for dealing with different scripts (e.g., Latin and Cyrillic) in the same document.

<i>Command</i>	<i>French</i>	<i>Greek</i>	<i>Polish</i>	<i>Russian</i>
<code>\abstractname</code>	Résumé	Περίληψη	Streszczenie	Аннотация
<code>\alsoname</code>	voir aussi	βλέπε επίσης	zob. także	см. также
<code>\appendixname</code>	Annexe	Παράρτημα	Dodatek	Приложение
<code>\bibname</code>	Bibliographie	Βιβλιογραφία	Bibliografia	Литература
<code>\ccname</code>	Copie à	Κοινοποίηση	Do wiadomości	исх.
<code>\chaptername</code>	Chapitre	Κεφάλαιο	Rozdział	Глава
<code>\contentsname</code>	Table des matières	Περιεχόμενα	Spis treści	Содержание
<code>\enclname</code>	P. J.	Συνημμένα	Załączniki	вкл.
<code>\figurename</code>	Figure	Σχήμα	Rysunek	Рис.
<code>\glossaryname</code>	Glossaire	Γλωσσάρι	Słowniczek	Словарь терминов
<code>\headtoname</code>		Προς	Do	вх.
<code>\indexname</code>	Index	Ευρετήριο	Skorowidz	Предметный указатель
<code>\listfigurename</code>	Table des figures	Κατάλογος Σχημάτων	Spis rysunków	Список иллюстраций
<code>\listtablename</code>	Liste des tableaux	Κατάλογος Πινάκων	Spis tabel	Список таблиц
<code>\pagename</code>	page	Σελίδα	Strona	с.
<code>\partname</code>	Deuxième partie	Μέρος	Część	Часть
<code>\prefacename</code>	Préface	Πρόλογος	Przedmowa	Предисловие
<code>\proofname</code>	Démonstration	Απόδειξη	Dowód	Доказательство
<code>\refname</code>	Références	Αναφορές	Literatura	Список литературы
<code>\seename</code>	voir	βλέπε	zob.	см.
<code>\tablename</code>	Table	Πίνακας	Tabela	Таблица

13-3-1

In French `\partname` also generates the part number as a word, e.g., “*Première, Deuxième, ...*”

Table 13.3: Language-dependent strings in babel (French, Greek, Polish, and Russian)

13.3.1 Translations of fixed texts

As discussed earlier, babel provides translations for document element names that \LaTeX uses in its document classes. The English versions of these strings are shown in Table 13.2 on page 305. Table 13.3 on page 309 shows the translations for a number of languages, with some of them not using the Latin script.

Apart from the translated strings in Table 13.3, the language definition files supply alternative versions of the command `\today`, as shown in the following example. We explicitly load the T2A encoding to typeset Cyrillic. To have `\today` translated, we supply the option `date` in the optional argument to `\foreignlanguage`:

```
\usepackage[T2A,T1]{fontenc} \usepackage{gentium}
\usepackage[catalan,bulgarian,british]{babel}
```

In England the date is ‘2nd February 2020’, while in Bulgaria it is ‘2 февруари 2020 г.’. Catalanians write ‘2 de febrer de 2020’.

In England the date is ‘`\today`’, while in Bulgaria it is ‘`\foreignlanguage[date]{bulgarian}{\today}`’. Catalanians write ‘`\foreignlanguage[date]{catalan}{\today}`’.

13-3-2

13.3.2 Available shorthands

Many of the language definition files provide shorthands. Some are meant to ease typing, whereas others provide quite extensive trickery to achieve special effects. You might not be aware of it, but \LaTeX itself defines a shorthand (although it is not called by that name) that you probably use quite often: the character tilde (~), which is used to enter a “nonbreakable” space.

As explained in Section 13.2.2, the default UTF-8 encoding makes shorthands for entering accented letters mostly unnecessary, so this section focuses on typographical tools and some special characters.

Unicode engines

With \LaTeX , many of the special effects can be achieved without explicit markup by means of what `babel` calls *transforms*. They are based on Lua’s pattern matching mechanism and can be defined by the user, although there are some predefined ones, explained in the `babel` manual.

The double quote

The most popular character to be used as a shorthand character is the double quote character ("), which should not replace, let us remember, the so-called typographical quotes (“”) when typing text. It is used in shorthands for Basque, Bulgarian, Catalan, Danish, Dutch, Estonian, Finnish, Galician, German, Icelandic, Italian, Latin, Norwegian, Polish, Portuguese, Russian, Serbian, Slovenian, Spanish, Swedish, Ukrainian, and Upper Sorbian, among others. Describing all uses of the double quote character as a shorthand character would be going too far. Instead, it is recommended that you check the documentation that comes with each language if you want to know the details. What can be said here is that its uses fall into a number of categories, each of which deserves a description and a few examples.

Insert accented letters For a number of languages, shorthands were created to facilitate typing accented characters. This mechanism was devised for the old 7-bit input and output encodings, and now this usage has become obsolete, but this is not true for all cases. For the Dutch language, for instance, an accent needs to be removed when the hyphenation point is next to the accented letter (although with \LaTeX there are tools to set nonstandard hyphenation rules like this without explicit markup).

Den Koning van Hispaniën heb ik altijd ge-
eerd! Den Koning van Hispaniën heb ik altijd
geëerd!

```
\usepackage[dutch]{babel}
```

```
Den Koning van Hispani"en heb ik altijd ge"eerd!  
Den Koning van Hispani"en heb ik altijd ge"eerd!
```

13-3-3

Insert special characters In the Catalan language a special glyph, the “geminated l”, is needed for proper typesetting [194].

```
\usepackage[catalan,english]{babel}
```

The “geminated l” appears in words
such as *intelligència* and *il·lusió*.

```
The ‘‘geminated-l’’ appears in words such as  
\foreignlanguage{catalan}{inte"ligència} and  
\foreignlanguage{catalan}{i"lusió}.
```

13-3-4

This character can also be typeset by using the commands `\lgem` and `\Lgem` or through the combinations “`\l.`” and “`\L.`” once `catalan` is selected.

Insert special quoting characters By default, \LaTeX supports single and double quotes: ‘quoted text’ and “quoted text”. This support is not desirable in European languages. Many have their own conventions and more often than not require different characters for this purpose. For example, in traditional Dutch typesetting, the opening quote should be placed on the baseline, in German typesetting the closing quote is reversed, and French typesetting requires guillemets. For Icelandic typesetting the guillemets are used as well, but the other way around — that is, pointing “inward” instead of “outward” (a convention also sometimes used in German typography).

English “quoted text” has quotes different from Dutch „quoted text” or German „quoted text” or French « quoted text ».

13-3-5

```
\usepackage[dutch,ngerman,french,english]{babel}
```

```
English ‘‘quoted text’’ has quotes different from
\selectlanguage{dutch}Dutch “‘quoted text’” or
\selectlanguage{ngerman}German “‘quoted text’” or
\selectlanguage{french}French \og quoted text\fg.
```

The T1 font encoding provides the guillemets (see Table 9.22 on page →I 763), but its support for French typesetting relies on the commands `\og` and `\fg`. These commands not only produce the guillemets but also provide proper spacing between them and the text they surround. Note that the `csquotes` package, discussed in Section 3.4.2 on page →I 179, provides convenient methods to automatically generate the right quotes based on language context and configuration setup.

Insert special hyphenation rules A number of languages have specific rules about what happens to characters at a line break. For instance, in older German spelling `..ck..` is hyphenated as `..k-k..`, and a triple `f` in a compound word is normally typeset as `ff` — except when hyphenated, in which case the third `f` reappears as shown in the example.

Brote bak-
ken

Farbstoff-
fabrik

13-3-6

```
\usepackage[german]{babel}
```

```
\fbox{\parbox[t]{1,5cm}{Brote ba"cken}} \quad
\fbox{\parbox[t]{1,5cm}{Farbsto"ffabrik}}
```

Insert special hyphenation indications A number of shorthands are used to inform \LaTeX about special situations with regard to hyphenation. For instance, in a number of languages it is sometimes necessary to prevent \LaTeX from typesetting a ligature — for example, in a compound word. This goal can be achieved by inserting a small kern between the two letters that would normally form a ligature. The shorthand “`|`” is available for this purpose in many language definitions.

Das deutsche Wort „Auflage“ sollte nicht so, sondern als »Auflage« gesetzt werden.

13-3-7

```
\usepackage[german]{babel}
```

```
Das deutsche Wort “‘Auflage’” sollte nicht so,
sondern als ">Auf"|lage"< gesetzt werden.
```

Another popular shorthand is "-", which indicates a soft or hard hyphen without suppressing hyphenation in the remainder of the word. Sadly, this has not been done consistently, because in Dutch, Portuguese, Catalan, or Danish, it is a hard hyphen, while in German, Spanish, Norwegian, Slovak, or Russian, it is a soft hyphen.

minister-

president

minister-

president

minister

president

```
\usepackage[dutch]{babel}
\fbbox{\parbox[t]{1cm}{minister"-president}} \quad
\fbbox{\parbox[t]{1cm}{minister\~president}} \quad
\fbbox{\parbox[t]{1cm}{ministerpresident}}
```

13-3-8

There is also "" (similar to "-", but does not print the -), "=" (whose meaning, again, depends on the language), and "~" (which usually inserts an explicit hyphen without a breakpoint). The following example shows the effects of these shorthands in German, using the same word:

1. Gutenberg-

Universität

2. Gutenberg

Universität

3. Gutenberg

Universität

4. Gutenberg-

Universi-

tät

5. Gutenberg-

Universität

Gutenberg-

Universität

Gutenberg

Universität

Gutenberg-

Universität

Gutenberg-

Universität

Gutenberg-

Universität

Gutenberg-

Universität

```
\usepackage[german]{babel}
\newcommand\present[1]{%
  \fbbox{\parbox[t]{31mm}{#1}}
  \fbbox{\parbox[t]{16mm}{#1}}
  \par}
1. \present{Gutenberg-Universität}
2. \present{Gutenberg"-Universität}
3. \present{Gutenberg""Universität}
4. \present{Gutenberg"=Universität}
5. \present{Gutenberg"~Universität}
```

13-3-9

The tilde

For the languages Basque, Galician, and Spanish, the construction ~- (as well as ~-- and ~---) produces a dash that disallows a line break after it. When the tilde is followed by any other character (or the empty group {}), it retains its original function as an “unbreakable space”. That is why the first two lines of the example are very loosely typeset.

En español, la raya que abre incisos

—como este— no debe quedar al final

de una línea.

```
\usepackage[spanish,activeacute]{babel}
En español, la raya que abre incisos ~---como
este--- no debe quedar al final de~una línea.
```

13-3-10

The colon, semicolon, exclamation mark, and question mark

For the languages Breton, French, Russian, and Ukrainian, these four characters are used as shorthands to facilitate the use of correct typographic conventions. For Turkish typography, this ability is needed for the colon and semicolon only, while in French it is extended to the guillemets when so requested with \frenchsetup. The convention is that a little white space should precede (or follow) these characters.

En français on doit mettre un « petit espace » devant la ponctuation double : comme cela ! For English this is not done: as shown here!

13-3-11

```
\usepackage[english,french]{babel}
\frenchsetup{og=«, fg=»}
```

En français on doit mettre un «petit espace»
devant la ponctuation double: comme cela!
\selectlanguage{english}
For English this is not done: as shown here!

This white space is added automatically by default, but this setting can be changed in a configuration file. The use of the colon as a shorthand character can lead to problems with other packages or when including PostScript files in a document. In such cases it may be necessary to disable this shorthand (temporarily) by using `\shorthandoff`, as explained in Example 13-2-5 on page 307.

The grave accent

The support for the languages Catalan and Hungarian makes it possible to use the grave accent (‘) as a shorthand character. The purpose of this shorthand for Catalan is just to facilitate the entering of accented characters, and one has to specify the option `activegrave` when loading `babel`. For Hungarian this shorthand also adds some characters to invoke the correct behavior at hyphenation points.

locsan	loc- csan
eddzünk	edz- dzünk
poggyász	pogy- gyász
Kodállya	Kodály- lya

13-3-12

menyiei	meny- nyei
vissza	visz- sza
pottyan	poty- tyan
rizzsel	rizs- zsel

```
\usepackage[hungarian]{babel}
\newcommand\present[1]
{\fbox{\parbox[t]{20mm}{#1}}
\fbox{\parbox[t]{8,5mm}{#1}}\par}
\present{lo'ccsan}
\present{e'ddzünk}
\present{po'ggyász}
\present{Kodá'llya}
\present{me'nnyei}
\present{vi'ssza}
\present{po'ttyan}
\present{ri'zzsel}
```

The equal sign

The support for the languages Latin and Turkish makes it possible to use the equal sign (=) as a shorthand character.

- When a Latin text is being typeset, the equal sign is defined to be a shorthand for adding a macron accent to the lowercase vowels (except, in pdfTeX, the medieval ligatures æ and œ). Because this shorthand may interfere with other packages, it must be explicitly requested when the package is loaded and additionally turned on with `\ProsodicMarksOn`.

```
\usepackage[latin.withprosodicmarks]{babel}
```

13-3-13

ā ē ī ō ū \ProsodicMarksOn =a =e =i =o =u

- When Turkish typesetting rules are to be followed, the equal sign needs to be preceded by a little white space. This is achieved automatically by turning the equal sign into a shorthand that replaces a preceding space character with a tiny amount of white space.

```
a =b      \usepackage[english,turkish]{babel}
a=b      \selectlanguage{english} a =b \par \selectlanguage{turkish} a =b
```

13-3-14

The disadvantage of having the equal sign turn into a space character is that it may cause many other packages to fail, including the usage of PostScript files for graphics inclusions. Make sure that the shorthand is turned off with `\shorthandoff`.

The greater than and less than signs

The support for the Spanish language makes it possible to use the “greater than” and “less than” signs (< and >) as shorthand characters for inserting a special quoting environment. This environment inserts different quoting characters when it is nested within itself. It supports a maximum of three levels of nested quotations. It also automatically inserts the closing quote signs when a new paragraph is started *within* a quote, as seen in front of “Las comillas ...”:

<p>La regla es: «dentro de las comillas latinas se usan las “inglesas y dentro de éstas las ‘sencillas’”.</p> <p>»Las comillas de seguir son como las de cerrar.»</p>	<pre>\usepackage[spanish]{babel} La regla es: <<dentro de las comillas latinas se usan las <<inglesas y dentro de éstas las <<sencillas>>>>. Las comillas de seguir son como las de cerrar.>></pre>
---	---

13-3-15

Note that when characters are turned into shorthands, the ligature mechanism in the fonts no longer works for them. In the T1 font encoding, for instance, a ligature is defined for two consecutive “less than” signs that normally results in typesetting guillemets. In the example above, the nested quote shows clearly that this does not happen. To deactivate the Spanish quoting style, just pass `es-noquoting` as a package option.

The period

The support for the Spanish language also allows the use of the period (.) as a shorthand character in math mode. Its purpose is to control whether decimal numbers are written with the comma (`\decimalcomma`) or the period (`\decimalpoint`) as the decimal character.

```
1000,10      \usepackage[spanish]{babel}
1000.10      \decimalcomma $1000.10$ \par \decimalpoint $1000.10$
```

13-3-16

Thanks to this feature, documents may be adapted easily to either convention, depending on the country (for example, dot in Mexico, comma in Spain). To deactivate this feature, pass `es-nodecimaldot` as a package option.

13.3.3 Language-specific commands

Apart from the translations and shorthands discussed above, some language definition files provide extra commands. Some of them are meant to facilitate the production of documents that conform to the appropriate typesetting rules. Others provide extra functionality not available by default in L^AT_EX. A number of these commands are described in this section.

Formatting dates

For some languages more than one format is used for representing dates in the Gregorian calendar, which is the only one supported out of the box by L^AT_EX. In these cases extra commands are provided to produce a date in different formats, although you can resort alternatively to the package `datetime2` by Nicola Talbot, which provides more sophisticated formatting options. The date in the next four examples is artificially set to a very important date in L^AT_EX's history;¹ see page →17 for the story behind this date.

In the Bulgarian tradition, months are indicated using uppercase roman numerals; for such dates the command `\todayRoman` is available.

		<code>\usepackage[bulgarian]{babel}</code>
	2 февруари 2020 г.	<code>\usepackage{XCharter}</code>
13-3-17	2. II. 2020 г.	<code>\today \par \todayRoman</code>

When writing in the Esperanto language two slightly different ways of representing the date are provided by the commands `\hodiaui` and `\hodiaun`.

	2-a de februaro, 2020	
	la 2-a de februaro, 2020	<code>\usepackage[esperanto]{babel}</code>
13-3-18	la 2-an de februaro, 2020	<code>\today \par \hodiaui \par \hodiaun</code>

When producing a document in the Greek language the date can also be represented with Greek numerals instead of arabic numerals. For this purpose the command `\Grtoday` is made available.

	2 Φεβρουαρίου 2020	<code>\usepackage[greek]{babel}</code>
	Β' Φεβρουαρίου ,ΒΚ'	<code>\usepackage{Alegreya}</code>
13-3-19		<code>\today \par \Grtoday</code>

The support for the Hungarian language provides the command `\ontoday` to produce a date format used in expressions such as “on February 10th”.

For the Upper and Lower Sorbian languages two different sets of month names are employed. By default, the support for these languages produces “new-style” dates, but “old-style” dates can be produced as well. The “old-style” date format for the Lower Sorbian language can be selected with the command `\olddatelsorbian`;

¹ This is the day when the L3 programming layer was integrated in the L^AT_EX format.

`\newdate`sorbian switches (back) to the modern form. For Upper Sorbian similar commands are available, as shown in the example:

	<code>\usepackage[usorbian,lsorbian]{babel}</code>
2. februara 2020	<code>\newdate</code> sorbian <code>\today</code> <code>\par</code>
2. maŕego roŕka 2020	<code>\olddate</code> sorbian <code>\today</code> <code>\par</code>
2. februara 2020	<code>\newdate</code> usorbian <code>\today</code> <code>\par</code>
2. maŕeho rŕŕka 2020	<code>\olddate</code> usorbian <code>\today</code>

13-3-20

In Swedish documents it is customary to represent dates with just numbers. Such dates can occur in two forms: YYYY-MM-DD and DD/MM YYYY. The command `\datesymd` changes the definition of the command `\today` to produce dates in the first numerical form; the command `\datesdmy` changes the definition of the command `\today` to produce dates in the second numerical format.¹

	<code>\usepackage[swedish]{babel}</code>
Default date format: 30 februari 1712	Default date format: <code>\today</code> <code>\</code>
<code>\datesymd</code> gives: 1712-02-30	<code>\verb \datesymd </code> gives: <code>\datesymd \today \</code>
<code>\datesdmy</code> gives: 30/2 1712	<code>\verb \datesdmy </code> gives: <code>\datesdmy \today</code>

13-3-21

Numbering

Counting is a natural and basic activity of the human thought, and many cultures have developed their own particular, and sometimes unique, ways to do it. Although the Indo-Arabic numeral system is widespread, there are many other ways to represent quantities, and even the decimal system has some differences across countries (for example, the decimal mark can be either a dot or a comma).

Letters in their alphabetic order are customary in enumerations, and each script requires its own characters. Even in a single script, letters can be selected in different ways. For example, in Spanish the *ñ* is inserted after the *n*, and in Italian some letters are discarded in some types of documents. It is worth noting that there is not always a unique “alphabet” even in a single language and that stylistic decisions are relevant.

Alphabetic counting has been available in \LaTeX since its beginnings with the commands `\alph` and `\Alph`, which assumes the bicameral system (lowercase and uppercase) in most Western languages.

The support for certain languages provides additional commands for representing numbers by letters. For the Esperanto language the commands `\esper` and `\Esper` are provided. The support for the Greek language changes the definition of `\alph` and `\Alph` to produce Greek letters, while the support for the Bulgarian language changes them to produce Cyrillic letters. The support for the Russian and Belarusian languages provides the commands `\asbuk` and `\Asbuk` as alternatives to the \LaTeX commands. Table 13.4 on the facing page compares the results of the different commands and their redefinitions for certain languages.

¹Fun fact: the date in the example was real — but only in Sweden.

	<i>default</i>		Esperanto		Greek		Russian		Bulgarian	
<i>value</i>	\alph\Alph	\esper\Esper	\alph\Alph	\asbuk\Asbuk	\alph\Alph	\asbuk\Asbuk	\alph\Alph	\asbuk\Asbuk	\alph\Alph	\asbuk\Asbuk
1	a	A	a	A	α'	A'	a	A	a	A
2	b	B	b	B	β'	B'	б	Б	б	Б
3	c	C	c	C	γ'	Γ'	в	В	в	В
4	d	D	ĉ	Ĉ	δ'	Δ'	г	Г	г	Г
5	e	E	d	D	ε'	Ε'	д	Д	д	Д

13-3-22

Table 13.4: Different methods for representing numbers by letters

In some languages an alternative way of writing numbers exists, often named “additive” and based on assigning a letter or a combination of them to denote the numbers 1 to 9, 10 to 90, 100 to 900, and so on. An archetypal case is Greek, with a system that was used in official publications at the end of the 19th century and the beginning of the 20th century. At present most Greeks use it for small numbers.

The knowledge of how to write numbers larger than 20 or 30 is not very widespread, being primarily used by the Eastern Orthodox Church and scholars. They employ this approach to denote numbers up to 999999. This system works as follows:

- Only numbers greater than 0 can be expressed.
- For the units 1 through 9 (inclusive), the letters alpha, beta, gamma, delta, epsilon, stigma, zeta, eta, and theta are used, followed by a mark similar to the mathematical symbol “prime”, called the “numeric mark”. Because the letter stigma is not always part of the available font, it is often replaced by the first two letters of its name as an alternative. In the babel implementation the letter stigma is produced, rather than the digraph sigma tau.
- For the tens 10 through 90 (inclusive), the letters iota, kappa, lambda, mu, nu, xi, omikron, pi, and qoppa are used, again followed by the numeric mark. The qoppa that appears in Greek numerals has a distinct zig-zag form that is quite different from the normal qoppa, which resembles the Latin “q”.
- For the hundreds 100 through 900 (inclusive), the letters rho, sigma, tau, upsilon, phi, chi, psi, omega, and sampi are used, also followed by the numeric mark.
- Using these rules, any number between 1 and 999 can be expressed by a group of letters denoting the hundreds, tens, and units, followed by *one* numeric mark.
- For the number range 1000 through 999000 (inclusive), the digits denoting multiples of a thousand are expressed by the same letters as above, this time with a numeric mark in front of this letter group. This mark is rotated 180 degrees and placed *under* the baseline. As can be seen in the example below, when two letter groups are combined, *both* numeric marks are used:

123456 in Greek notation: ρ,χ,γυνς'

987654 in Greek notation: Δ,Π,ZXNΔ'

```
\usepackage{garamondlibre} \linespread{1.1}
\usepackage[english,greek]{babel}
\newcommand\eng[1]{\foreignlanguage{english}{#1}}

123456 \eng{in Greek notation:} \greeknumeral{123456} \par
987654 \eng{in Greek notation:} \Greeknuneral{987654}
```

13-3-23

In ancient Greece yet another numbering system was used, which closely resembles the roman one in that it employs letters to denote important numbers. Multiple occurrences of a letter denote a multiple of the “important” number; for example, the letter I denotes 1, so III denotes 3. Here are the basic digits used in the Athenian numbering system:

- I denotes the number one (1).
- II denotes the number five (5).
- Δ denotes the number ten (10).
- H denotes the number one hundred (100).
- X denotes the number one thousand (1000).
- M denotes the number ten thousand (10000).

Moreover, the letters Δ, H, X, and M, when placed under the letter II, denote five times

their original value; for example, the symbol Ⅻ denotes the number 5000, and the symbol Ⅹ denotes the number 50. Note that the numbering system does not provide negative numerals or a symbol for zero.

The Athenian numbering system, among others, is described in *A History of Mathematical Notations* [29, pp. 21–29]. This numbering system is supported by the package `athnum`, which comes with the `babel` system and implements the command `\athnum`. Note that only a few font families besides Computer and Latin Modern provide the required characters, among them Kerkis and Garamond Libre.

13-3-24

6284 in Athenian notation:

ⅯⅩHHⅯ△△ⅢⅢ

```
\usepackage[english,greek]{babel}
\usepackage{garamondlibre,athnum}
\newcommand\eng[1]{\foreignlanguage{english}{#1}}
6284 \eng{in Athenian notation:} \ \ \athnum{6284}
```

In Icelandic documents, numbers require special formatting to be typeset correctly. For this purpose the command `\tala` is provided. It takes an optional argument, which can be used to replace the decimal separator used, such as for use with the `dcolumn` package.

The `dcolumn` package formats numbers in math mode, which explains the different fonts in the two parts of the example (this book does not change the default math setup, so the digits inside the box are taken from Computer Modern):

13-3-25

3 141,592 653
3,141.592,653

3,14
123,456 7
9 876,543

```
\usepackage[english,icelandic]{babel}
\usepackage{dcolumn} \newcolumntype{d}{D{,}}{\decimalsep}{-1}}
\tala{3141,592653} \par
\foreignlanguage{english}{\tala{3141,592653}}\par \bigskip
\begin{tabular}{|d|} \hline
3,14 \ \ \
\tala[,]{123,4567} \ \ \ \tala[,]{9876,543} \ \ \ \hline
\end{tabular}
```

Miscellaneous extras

In French typesetting it is customary to print family names in small capitals, *without* hyphenating a name. For this purpose the command `\bsc` (boxed small capitals) is provided. Abbreviations of the French word “numéro” should be typeset according to specific rules; these have been implemented in the commands `\no` and `\No`. Finally, for certain enumerated lists the commands `\primo`, `\secundo`, `\tertio`, and `\quarto` are available when typesetting in French.

... for French

13-3-26

Leslie LAMPORT N° 9 1° 3°

```
\usepackage[french]{babel}
Leslie~\bsc{Lamport} \quad \No9 \ \ \primo \ \ \tertio
```

In some languages, e.g., Italian, it is customary to write together the article and the following noun — for example, “nell’altezza”. To carry out the hyphenation of such constructs the character ’ is made to behave as a normal letter.

... for Catalan,
French, and Italian

... for Hungarian

In the Hungarian language the definite article can be either “a” or “az”, depending on the context. Especially with references and citations, it is not always known beforehand which form should be used. The support for the Hungarian language contains commands that know the rules dictating when a “z” should be added to the article. These commands all take an argument that determines which form of the definite article should be typeset together with that argument.

```
\az{text} \Az{text}
```

These commands produce the article and the argument. The argument can be a star (as in `\az*`), in which case just the article is typeset. The form `\Az` is intended for the start of a sentence.

```
\aref{text} \Aref{text} \apageref{text} \Apageref{text}
```

The first two commands should be used instead of `a(z)~\ref{label}`. When an equation is being referenced, the argument may be enclosed in parentheses instead of braces. For page references use `\apageref` (or `\Apageref`) to allow \LaTeX to automatically produce the correct definite article.

```
\acite{text} \Acite{text}
```

For citations the command `\acite` should be used. Its argument may be a list of citations, in which case the first element of the list determines which form of the article should be typeset.

... specials for math

In Eastern Europe a number of mathematical operators have a different appearance in equations than they do in “the Western world”. Table 13.5 on the next page shows the relevant commands, which can be used irrespective of the current language. The Russian commands are also valid for Bulgarian and Ukrainian language support. The package `grmath`, which comes as part of the Greek style, changes the definitions of these operators to produce abbreviations of their local names. The package can be used only in conjunction with the `greek` option of `babel`.

13.3.4 Layout considerations

Some of the language support files in the `babel` package provide commands for automatically changing the layout of the document. Some simply change the way \LaTeX handles spaces after punctuation characters or ensure that the first paragraph that follows a section heading is indented. Others go much further.

Spaces after
punctuation
characters

In *The \TeX book* [84, pp.72–74], the concept of extra white space after punctuation characters is discussed. Good typesetting practice mandated that inter-sentence spaces behave a little differently than interword spaces with respect to shrinkage and expansion (during justification). However, this practice is not considered desirable in all cases — even in English it seems to be falling into disfavor, so for a number of languages (for example, Breton, Bulgarian, Czech, Danish, Estonian, Finnish, French,

<i>LaTeX</i>		<i>Serbian</i>		<i>Russian</i>	
<code>\tan</code>	tan	<code>\tg</code>	tg	<code>\tg</code>	tg
<code>\cot</code>	cot	<code>\ctg</code>	ctg	<code>\ctg</code>	ctg
<code>\sinh</code>	sinh	<code>\sh</code>	sh	<code>\sh</code>	sh
<code>\cosh</code>	cosh	<code>\ch</code>	ch	<code>\ch</code>	ch
<code>\tanh</code>	tanh	<code>\th</code>	th	<code>\th</code>	arctg
<code>\coth</code>	coth	<code>\cth</code>	cth	<code>\cth</code>	cth
<code>\csc</code>	csc			<code>\cosec</code>	cosec
<code>\arcsin</code>	arcsin	<code>\arsh</code>	arsh		
<code>\arccos</code>	arccos	<code>\arch</code>	arch		
<code>\arctan</code>	arctan	<code>\arctg</code>	arctg	<code>\arctg</code>	arctg
		<code>\arcctg</code>	arcctg	<code>\arcctg</code>	arcctg (extra)

13-3-27

*Note that the redefinition of `\th` conflicts with its standard use as an LICR command for *p* (thorn); therefore, `babel` restricts this redefinition to *math mode* in Cyrillic texts.*

Table 13.5: Alternative mathematical operators for Eastern European languages

German, Norwegian, Russian, Spanish, Turkish, and Ukrainian) this feature is switched off with a command called `\frenchspacing` (even though it is *not* used for French).

Another layout concept that is built into most \LaTeX classes is the suppression of the paragraph indentation for the first paragraph that follows a section heading. Again, for some languages this behavior is wrong; the support for French, Serbo-Croatian, and Spanish changes it to have *all* paragraphs indented. In fact, you can request this behavior for any document by loading the package `indentfirst`.

*Paragraph indentation
after heading*

The support for French takes this somewhat further to accommodate the typesetting rules used in France. If this language has been set as the main one, it changes the general way lists are typeset by \LaTeX by reducing the amount of vertical white space in them; this change is applied globally to preserve the consistency in the document appearance. For the `itemize` environment, it removes all vertical white space between the items and changes the appearance of the items by replacing “•” with a dash.

Layout of lists

	<code>\usepackage[french]{babel}</code>
Some text with a list.	Some text with a list.
— item 1	<code>\begin{itemize}</code>
— item 2	<code>\item item 1 \item item 2</code>
	<code>\end{itemize}</code>
And some text following.	And some text following.

13-3-28

`\frenchsetup{options}`

For documents that are typeset in more than one language, the support for French provides a way to customize how several layout elements should be adapted. Different results can be achieved by using key-value options in `\frenchsetup` in the preamble of the document. An example is `StandardLayout=true`, which forces `babel` not to

interfere with lists, first paragraphs indentation, or footnotes. There are many options for fine-tuning the typographical conventions.

Layout of footnotes

For instance, in the French typesetting tradition, footnotes are handled differently than they are in the Anglo-American tradition. In the running text, a little white space should be added before the number or symbol that calls the footnote. This behavior is optional and can be selected by using the `AutoSpaceFootnotes` key in `\frenchsetup`.

The text of the footnote can also be typeset according to French typesetting rules; this result is achieved by using the key `FrenchFootnotes`, but the commands `\StandardFootnotes` and `\FrenchFootnotes` are also available for local changes (`\StandardFootnotes` in minipages, for instance, because the counter is `\alph`).

Some text ^a.

a. with a footnote

Some text ^a.

^awith a footnote

```
\usepackage[french,english]{babel}
\frenchsetup{AutoSpaceFootnotes,FrenchFootnotes}

\begin{minipage}{70pt} Some text\footnote{with a footnote}.
\end{minipage}

\selectlanguage{french}\StandardFootnotes
\begin{minipage}{70pt} Some text\footnote{with a footnote}.
\end{minipage}
```

13-3-29

Layout of captions

Another change performed by the `babel` support for the French language is that the colon in captions for tables and figures is replaced with an en-dash when one of the document classes of standard \LaTeX is used.

Internal
commands
redefined for
magyar

The support for typesetting Hungarian documents goes even further: it redefines a number of internal \LaTeX commands to produce correct captions for figures and tables. Using the same means, it changes the layout of section headings. The definition of the `theorem` environment is changed as well. As explained above, such changes may lead to unexpected and even unwanted behavior, so be careful.

Right to left
typesetting

To support typesetting Hebrew or Arabic documents, even more drastic changes are needed; they are treated in Section 13.5 on page 332.

13.3.5 Languages and font encoding

As shown in some of the earlier examples, some languages cannot be supported by, for instance, simply translating some texts and providing extra support for special hyphenation needs. Many languages require characters that are not present in \LaTeX 's T1 encoding. For some, just a few characters are missing and can be constructed from the available glyphs; other languages are not normally written using the Latin script. Some of these are supported by the `babel` system.

Extensions to the T1 encodings

For some languages just a few characters are missing in the T1 encoding, and they might not even be directly accessible on the keyboard. When the missing characters can be constructed from the available glyphs, it is relatively easy to rectify this situation. Such is the case for the Old Icelandic language. It needs a number of

characters that can be represented by adding the “ogonek” to available glyphs. To access them, you can use the shorthands in the next example, which are activated explicitly in the package options:

13-3-30

ø Ø ó Ô õ Ę Ę Ę

```
\usepackage[icelandic.utf8old]{babel}
"o "O "ó "Ó "õ "Ė "Ė "Ė
```

Basic support for switching script-related features

Because scripts, writing directions, and so on, are strongly linked to each language, the babel core provides no user interface to set them. Instead, they are adjusted as needed when a language is selected. This high-level interface guarantees all the required features are set and applied consistently.¹

As to writing directions, the model to deal with them in 8-bit engines like pdfTeX has many issues and requires a lot of manual intervention, which has been provided in different ways, depending on the language. See the manual for the language styles requiring bidi writing, particularly Arabic (which is supported with the arabi package, by Youssef Jabri) and Hebrew. Something similar can be said of XeTeX, whose bidirectional model is basically the same as that of pdfTeX.

On the other hand, with LuaTeX, a more modern approach, based on the Unicode algorithm, can be applied so that the writing direction is switched automatically. See Section 13.5 on “Complex scripts” for further details, but here this macro is worth mentioning.

```
\babelsublr{text}
```

There are cases in which the Unicode algorithm fails and makes the wrong guess. An example is the string “2.5”, which must be shown in this order when it refers to a real number, but also, and depending on the language, “5.2” when it refers to a section with a subsection. With LuaTeX the latter can be entered as `\babelsublr{2}.\babelsublr{5}`, which isolates the numbers from the dot. See the babel manual for the option `layout=counters`, which does this for you in some typical cases.

```
\ensureascii{text}
```

A few encodings used for text, notably LGR or X2, are not LICR-savvy, and the ASCII range contains non-Latin letters (for example, the slot for the letter “a” is replaced in the former by the Greek letter alpha). This command attempts to typeset its argument in a font encoding respecting the ASCII encoding, typically T1 or OT1, and can be used in the scope of those problematical encodings so that ASCII text is correctly typeset.

¹A few macros to deal with those changes have been available for many years (for example, `\cyrillicencoding`), but they are deprecated, because even the Latin script may require several encodings.

13.4 Support for Cyrillic and Greek

The Greek and Cyrillic scripts are closely related to the Latin one, and it is not surprising that among the first non-Latin scripts to be supported by \LaTeX were the former. Although currently they are usually best typeset with the Unicode engines, pdf \TeX is still widely used, and this section is devoted to this engine.

Unicode engines

In X \TeX and Lua \TeX , you can resort, in addition, to the mechanism described below in “Complex scripts” (Section 13.5), which supports not only Monotonic and Polytonic Greek, but also Ancient Greek.

13.4.1 The Cyrillic alphabet

The Cyrillic alphabet is used by several of the Slavic languages in Eastern Europe, as well as for writing tens of languages used in the territory encompassed by the former Soviet Union. Vladimir Volovich and Werner Lemberg, together with the \LaTeX Project Team, have integrated basic support for the Cyrillic language into \LaTeX . This section addresses the issues of Cyrillic fonts, the encoding interface, and their integration with `babel`.

Historically, support for Russian in \TeX has been available from the American Mathematical Society [13]. The AMS system uses the `wncyr` fonts and is based on a transliteration table originally designed for Russian journal names and article titles in the journal *Mathematical Reviews*. In this journal the AMS prefers that the same character sequence in the electronic files produce either the Russian text with Russian characters or its transliteration with English characters, without any ambiguities.

However, with the spread of \TeX in Russia, proper support for typesetting Russian (and later other languages written in the Cyrillic alphabet) became necessary. Over the years several 7- and 8-bit input encodings were developed, as well as many font encodings. The Cyrillic system is designed to work for any 8-bit input encoding and is able to map all of them onto a few Cyrillic font encodings, each supporting a number of languages.

Font encodings

For compatibility reasons, only the upper 128 characters in an 8-bit \TeX font are available for new glyphs. Because the number of glyphs in use in Cyrillic-based languages during the 20th century far exceeds 128, four “Cyrillic font encodings” have been defined [14]. Three of them — T2A, T2B, and T2C — satisfy the basic structural requirements of \LaTeX ’s T* encodings and, therefore, can be used in multilingual documents with other languages being based on standard font encodings.¹

The work on the T2* encodings was performed by Alexander Berdnikov in collaboration with Mikhail Kolodin and Andrew Janishevsky. Vladimir Volovich provided the integration with \LaTeX . Table 13.6 shows the layout of the T2A encoding.

¹The fourth Cyrillic encoding, X2, contains Cyrillic glyphs spread over the 256 character positions and is thus suitable only for specific, Cyrillic-only applications. It is not discussed here.

	'0	'1	'2	'3	'4	'5	'6	'7	
'00x	`	´	^	~	¨	˜	°	˘	"0x

	"8	"9	"A	"B	"C	"D	"E	"F	

Characters marked in *blue* need to be present (in their specified positions) in every text encoding, as they are transparently passed through T_EX.

Table 13.6: Glyph chart for a T2A-encoded font (larm1000)

Two other \LaTeX Cyrillic font encodings exist, although they are best avoided: the 7-bit OT2 encoding developed by the American Mathematical Society, and the 8-bit LCY encoding, which are incompatible with the \LaTeX 's T* encodings and, therefore, unsuitable for typesetting multilingual documents. The OT2 encoding was designed in such a way that a transliterated source could be used to produce the text in that form and in the Cyrillic alphabet.

The basic \LaTeX distribution come with all the encoding and font definition files for handling Cyrillic. The `babel` package includes support for Bulgarian, Russian, Belarusian, and Ukrainian, among others. Together with the font files, \LaTeX can use this package to provide complete support for typesetting languages based on the Cyrillic alphabet. The Cyrillic font encodings support the languages listed in the document `cyrguide.pdf`. Note that some languages, such as Bulgarian and Russian, can be properly typeset with more than one of those encodings.

There are hyphenation patterns for several languages based on the T2A encoding in the `hyph-utf8` bundle, which is the default in current \TeX distributions. A collection of hyphenation patterns for the Russian language that supports the T2* encodings, as well as other popular font encodings used for Russian typesetting, is available in the `ruhyphen` distribution on CTAN (`language/hyphenation/ruhyphen`).

Fonts

The default font family with \LaTeX is Knuth's Computer Modern, in its 8-bit (T1-encoded EC fonts) incarnation. Olga Lapko and Andrey Khodulev developed the LH fonts, which provide glyph designs compatible with the Computer Modern font family and covering all Cyrillic font encodings. They provide the same font shapes and sizes as those available for its Latin equivalent, the EC family, and are now part of the CM-Super fonts package.

Other fonts can also be used, provided that their \TeX font encoding is compatible with the T2* encodings, as several examples in this chapter show. More can be found in Section 10.12.

Using Cyrillic in your documents

Support for Cyrillic fonts in pdf \TeX is based on the standard `fontenc` package and assumes by default that UTF-8 is used as the input encoding. If your files are stored in one of the legacy 8-bit input encodings, then `inputenc` is also needed. For instance, one can write the following in the preamble of the document:

```
\usepackage[T2A]{fontenc} \usepackage[koi8-r]{inputenc}
\usepackage[russian]{babel}
```

The input encoding `koi8-r` (KOI8 optimized for Russian) is just one of the many alternatives to UTF-8 available for Cyrillic texts:

`cp855` Standard MS-DOS Cyrillic code page.

`cp866` Standard MS-DOS Russian code page. Several variants, distinguished by differences in the code positions 242–254, exist: `cp866av` (Cyrillic Alternative),

cp866mav (Modified Alternative Variant), cp866nav (New Alternative Variant), and cp866tat (for Tatar).

cp1251 Standard MS Windows Cyrillic code page.

koi8-r Standard Cyrillic code page that is widely used on UN*X-like systems for Russian language support. Variants for Ukrainian are koi8-u and koi8-ru. An ECMA variant (ISO-IR 111 ECMA) is isoir111.

iso88595 ISO standard ISO 8859-5 (also called ISO-IR 144).

maccyr Apple Macintosh Cyrillic code page (also known as Microsoft cp10007) and macukr, the Apple Macintosh Ukrainian code page.

ctt, dbk, mnk, mos, ncc Mongolian code pages.

Not all of these code pages are part of the standard inputenc distribution, so some may have to be obtained separately.

When more than one input encoding is used within a document, you can use the `\inputencoding` command to switch between them. To define the case of text, two standard \LaTeX commands, `\MakeUppercase` and `\MakeLowercase`, can produce uppercase or lowercase, respectively. The low-level \TeX `\uppercase` and `\lowercase` should never be used in \LaTeX and will not work for Cyrillic.

In the previous example of a preamble, the font encoding to be used was explicitly declared. For multilingual documents *all* encodings needed should be enumerated via the `\usepackage[...]{fontenc}` command. Changing from one font encoding to another can be accomplished by using the `\fontencoding` command, but it is advisable that such changes be performed by a higher-level interface such as the `\selectlanguage` command. In particular, when using `babel`, you can simply write

```
\usepackage[russian]{babel}
```

where `babel` will automatically choose (and load) the default font encoding for Russian, which is T2A, when it is available.

Indexes and bibliographies

There are a few tools to deal with indexes and bibliographies based on the default UTF-8 encoding. For indexes, `upmendex` is an alternative for *MakeIndex* supporting Unicode and many languages, even with pdf \TeX . It is described in Chapter 14, so here we limit ourselves to the steps required to compose an index with Russian terms. In the document, set the index up in the preamble in the same way as with *MakeIndex*. An example is:

```
\documentclass{article}
\usepackage[T2A]{fontenc} \usepackage[russian]{babel}
\usepackage{makeidx}      \makeindex
\begin{document}
один\index{один} два\index{два}
\printindex
\end{document}
```

Although the default collator does not do a bad job (for example, “ë” is correctly sorted under “e”), it is advisable to set the locale as explained in Section 14.3.2, where the reader can find further information on customizing upmindex. Just create a file containing the line:

```
icu_locale "ru"
```

and then include it in the list of styles. Thus, if you name the file `ru_locale.ist`, you have to run `upmindex -s ru_locale <filename>.idx` to use it.

For bibliographic references, `biblatex` and `biber` provide a convenient replacement for `BibTeX`. The package and program are Unicode aware and work smoothly with the three main engines. They are described in detail in Chapters 15 and 16.

13.4.2 The Greek alphabet

Greek support in `babel` comes in two variants: the one-accent `monotoniko` (the default), which is used in most cases in everyday communications in Greece today, and the multi-accent `polutoniko`, which has to be specified as an attribute, as explained in Section 13.2.3. These variants are mutually exclusive, and they cannot be combined in a single document. This limitation does not exist with the interface explained in the next section, but it requires $X_{\text{T}}\text{TeX}$ or LuaTeX .

The first family of Greek fonts for $\text{T}_{\text{E}}\text{X}$ was created during the mid-1980s by Silvio Levy [120]. Other developers improved or extended these fonts or developed their own Greek fonts.

In `babel` the Greek language support is maintained by Günter Milde, based on the original work of Claudio Beccari in collaboration with Apostolos Syropoulos, who developed the Greek `cb` font family [11]. In their paper these authors discuss in some detail previous efforts¹ to support the Greek language with $\text{T}_{\text{E}}\text{X}$.

It relies on the `LGR` encoding, whose layout is shown in Table 13.7 on the next page. Although it is automatically loaded with the `greek` option of `babel`, it is advisable to request it explicitly with `fontenc`, as any other encoding. The `cb` fonts were originally devised as a companion to the default Computer Modern family supporting this encoding, but, as shown in Section 10.11 on page 106, there are currently more fonts in the `LGR` encoding to choose from.

It should be stressed that this encoding does not conform to the `LICR` conventions because it has no ASCII glyphs at all. This can lead to potential conflicts in multilingual documents, which in many cases can be dealt with by using the command `\ensureascii`, but not always. This is one of the reasons why you should consider $X_{\text{T}}\text{TeX}$ or LuaTeX instead of pdfTeX for Greek.

It is possible to use Latin alphabetic characters for inputting Greek according to the transliteration scheme shown in Table 13.8 on page 330. This table shows that the Latin “v” character has no direct equivalent in the Greek transcription. In fact, it is used to indicate that one *does not* want a final sigma. For example, “sv” generates a median form sigma although it occurs in a final position.

¹A more recent overview about 25 years of Greek typesetting with $\text{T}_{\text{E}}\text{X}$ is given in [43].

Characters marked in *blue* should be ASCII characters in every L^AT_EX text encoding (compare Table 13.6 on page 325), as they are transparently passed through T_EX. In LGR this is not the case for A-Z and a-z, which can produce problems in multilingual documents.

Table 13.9: LGR ligatures producing single-accented glyphs

By default, the `greek` option of `babel` uses `monotoniko` Greek. Multi-accented mode is requested by specifying the language attribute `polutoniko` for the `greek` option:

```
\usepackage[greek]{babel} \languageattribute{greek}{polutoniko}
```

For both modes, some seldom-used characters have been defined to behave like letters (`\catcode 11`). For `monotoniko` Greek, this is the case for the characters `'` and `"`. In the `polutoniko` variant, the characters `<`, `>`, `~`, `'`, and `|` also behave like letters. The reason for this behavior is that the LGR encoding contains many ligatures with these characters to produce the right glyphs; see Table 13.9. Table 13.10 shows the available composite accent and spiritus combinations.

13.5 Complex scripts

Typesetting documents in the so-called complex scripts has been always a nuisance with “traditional” \TeX . With the advent of \XeTeX and \LuaTeX , it is now possible to write in any language of the world, provided you have a suitable font at hand, so `babel` has been extended to deal with those scripts and their needs for line breaking, layout, bidirectional behavior, etc.

13-4-3

Table 13.10: Available composite spiritus and accent combinations

In many of these languages, an alternative way to define them is required, activated with the package option `provide=*`, as shown in the examples below. It resorts in turn to a specific macro named `\babelprovide`, described in the `babel` manual in full detail.

Because the default font families cover only the Latin script, you may need to set up different ones with `\babelfont`, which provides a high-level interface to `fontspec`. It defines not only the corresponding font for the family given in its first argument, but also passes the information required to render it correctly, according to the peculiarities of each script. The fonts used here are available in \TeX Live, and they should work out of the box in this distribution. For Greek and Cyrillic, refer to Chapter 10, because these scripts are included in many fonts.

Chinese + Japanese + Korean, a.k.a. CJK

Given that Chinese and Japanese are written without spaces (and often Korean, too) and line breaking is possible between many characters (but not all), `babel` applies some basic rules based on the Unicode ones for this purpose.

	<code>\usepackage[japanese, provide=*]{babel}</code>
	<code>\babelfont{rm}{IPAexMincho}</code>
義は険しい山よりも重く、死	義は険しい山よりも重く、死は大鳥の羽よりも軽い。
は大鳥の羽よりも軽い。	

13-5-1

In languages of this group, lines are written often top to bottom, which are in turn written right to left, but for a complete solution you must resort to dedicated packages like `CJK`, `kotex`, `luatexja`, or `C\TeX`, because `babel` is restricted to horizontal writing. Some of these packages rely on `up\TeX`, an extension to the \TeX program that addresses this typographic need.

Indic scripts

Indic scripts may contain what are named clusters, combinations of consonants with a special graphical representation. In addition, letters are visually reordered so that a vowel may precede the corresponding consonant. Currently, the best option in most

cases is to resort to Unicode engines, because the script complexities are handled by the fonts. With LuaTeX, the HarfBuzz renderer (instead of the default one) is usually to be preferred; see the fontspec manual for further details on the available font renderers.

```
\usepackage[hindi, provide=*]{babel}
\babelfont{rm}[Renderer=HarfBuzz]{FreeSerif}
```

जिस की लाठी उस की भैंस. जिस की लाठी उस की भैंस.

13-5-2

Line breaking is often done without a hyphen, like in Thai. This language is, in addition, written without word spaces, so a special line-breaking algorithm is applied in both Unicode engines to insert flexible spaces at appropriate places in order to justify the text.

Bi-directional (bidi) scripts

Arabic, Hebrew, and Syriac among others require bidi writing, which must be explicitly activated with a package option. In the case of LuaTeX, which is the recommended engine in those languages, the option is `bidi=basic`. With it, left-to-write characters, including numerals, are automatically set in the correct direction. In the case of Arabic and Syriac, the letter shapes change according to their positions in a word.

```
\usepackage[bidi=basic, arabic, provide=*]{babel}
\babelfont{rm}{Amiri}
```

اجتنب مصاحبة الكذاب فإن اضطرت إليه فلا تصدقه. اجتنب مصاحبة الكذاب فإن اضطرت إليه فلا تصدقه.

13-5-3

Arabic documents also have right-to-left layouts, which means margins, lists, footnotes, tables, and other elements must be readjusted. This can be done in LuaTeX in the most typical cases with minimal internal changes in the \LaTeX code, because it has built-in primitives to set the origin of pages, boxes, and the like, so `babel` attempts to do it, but \XeTeX requires patching a good deal of \LaTeX macros and packages, and an external package is used (`bidi`, by Vafa Khalighi). Text justification with *kashida* (short horizontal extenders) can be accomplished in LuaTeX with user-definable rules.

13.6 Tailoring babel

As explained earlier, typographic rules are not always set in stone and may differ even among publishing houses. Therefore, users should be able to tailor easily the language styles, or even to create new ones from scratch for them to be adapted to their own needs. In most cases, this is best done with the help of dedicated packages, but in some cases all you need is either to readjust the decisions taken by `babel` or to make changes that are language or culture dependent.

This section starts with some tips about how to customize the styles and then describes briefly how to create `.ldf` files or, alternatively, descriptive `.ini` files based on key/value pairs. Some of these changes are based on the command `\babelprovide`.

13.6.1 User level

We start with describing the kind of changes that you may want to do in the preamble of an individual document, if you are not satisfied with the defaults offered by babel or by a language support package. Obviously the same commands are also used in class or package files to provide you with the initial configurations.

Modify caption strings

Although there are more or less traditional ways to name chapters, tables, and so on, they are not always unique, and the default values may need changes. For example, in Spanish *Table* has been traditionally named *Cuadro*, but *Tabla* is also frequent.

Redefining directly the macro (in this case `\tablename`) in the preamble or inside `\AtBeginDocument` may not work because the original definition is restored at every language selection. You must make sure the new definition correctly replaces the original one, and the best way in most cases is with `\setlocalecaption`, as shown:

```
\setlocalecaption{spanish}{table}{Tabla}
```

In this particular example, the macro name to be set is built from the second argument by adding `name`. These definitions should contain only the string and perhaps some basic formatting, but not, say, counters or labels.

Hyphenation rules

Some languages may follow several criteria to hyphenate words, as the well-known case of British vs. American English demonstrates. Furthermore, some disciplines like chemistry may require their own rules. On the other hand, if there are no hyphenation patterns for a language, you may want to apply those for a similar language. This can be done in your documents with `\babelprovide` in the following way, provided `language.dat` (described in Section 13.6.2) has been configured to load a set of patterns with the given name:

```
\babelprovide[hyphenrules=ngerman-x-2019-04-04]{german}
```

Another set of hyphenation parameters you may want to modify are the language-specific values for `\lefthyphenmin` (minimum number of characters on the left before the first hyphen point) and `\righthyphenmin` (minimum numbers on the right), which are stored in `\(language)hyphenmins`.

```
\providehyphenmins{lang}{hyphenmins}    \(\language)hyphenmins
```

The command `\providehyphenmins` provides a *default* setting for these hyphenation parameters by defining `\(language)hyphenmins` unless it is already defined for some reason. The babel package detects whether the hyphenation file explicitly sets `\lefthyphenmin` and `\righthyphenmin` and automatically defines

`\(language)hyphenmins`, in which case the `\providehyphenmins` declaration has no effect.

The syntax inside `babel` is storage optimized, dating back to the days when every token counted. Thus, the argument *hyphenmins* contains the values for both parameters simply as two digits, making the assumption that you never want a minimum larger than 9. If this assumption is wrong, you must surround the values with braces within *hyphenmins*. For example,

```
\providehyphenmins{german}{{10}{5}}
```

would request leaving at least ten characters before a hyphen and at least five characters after it (thus essentially never hyphenate — except monsters such as *Donaudampfschiffahrtkapitänsmütze*).

If you want to explicitly overwrite the settings regardless of any existing specification, you can do so by providing a value for `\(language)hyphenmins` yourself. For instance,

```
\renewcommand*\germanhyphenmins{{4}{3}}
```

never considers hyphenation points with fewer than four letters before and three letters after the hyphen. Thus, LaTeX will never hyphenate a word with less than seven characters in that language.

Hyphenation patterns are built with a certain setting of these parameters in mind. Setting their values lower than the values used in the pattern generation may merely result in incorrect hyphenation. It is possible, however, to use higher values in which case the potential hyphenation points are simply reduced.

Counters and labels

Decimal numerals have different shapes in different scripts and are best entered directly in the final form, but sometimes and for practical reasons a conversion from the Western forms can be useful, particularly with automatically generated numbers. In languages loaded with the procedure described in “Complex scripts”, you can map the `\arabic` counter to the local forms by setting the option `maparabic` in the optional argument of `\babelprovide`.

Babel provides a simple tool to create your own numeral systems, including additive ones, in case those provided by default do not meet your requirements. Some `.ini` files provide them, but even so there might be the need to define more. This can be done with `\babelprovide` as shown in the following example, which defines two variants for the masculine ordinal:

```
\usepackage[spanish]{babel}
\babelprovide[counters/masc = 1\sptext{o} 2\sptext{o} 3\sptext{o},
               counters/masc.short = 1\sptext{er} 2\sptext{o} 3\sptext{er}]
               {spanish}
\localnumeral{masc.short}{3} \quad
\localnumeral{masc}{3}
```

3.^{er} 3.^o

13-6-1

The command `\localenumeral` prints the corresponding representation for a number. There is a companion named `\localecounter` whose second argument is a counter name, like `page` or `section`.

Executing some code when languages are selected

When a language is selected and unselected, `babel` executes several macros that set its behavior. Two of them are particularly important because they are responsible for most of the work, and therefore you need to know them in order to understand how to configure the language.

`\extras<language>`

The macro `\extras<language>` contains all extra definitions needed for the language `<language>` being defined in an `.ldf` file. Such extras can be commands to turn shorthands on or off, to make certain characters active, to initiate French spacing, to position umlauts, and so on.

`\noextras<language>`

To allow switching between any two languages, it is necessary to return to a known state for the \TeX engine — in particular, with respect to the definitions initiated by the command `\extras<language>`. The macro `\noextras<language>` must contain code to revert all such definitions so as to bring \TeX back to a known state.

`\AddBabelHook[<language>]{<label>}{<hook>}{<code>}`

With this command, code can be injected at several places, like before and after `\extras<language>`. For example, if you want French spacing for every language, just say:

```
\AddBabelHook{nonfrench}{afterextras}{\frenchspacing}
```

Here `nonfrench` is just a label to identify the hook, and `afterextras` is the place where the piece of code in the following argument is executed and whose meaning in this case is self-explanatory. When the optional argument for the language is omitted, as in this case, it applies for all languages.

With the optional argument, the `<code>` is executed only with the specified `<language>`. The following line in a document with `english` and `ngerman` makes accessible in the former language some shorthands defined in the latter:

```
\AddBabelHook[english]{en-de-shorthands}{afterextras}
{\languageshorthands{ngerman}}
```

You may also need to activate them as user shorthands in the preamble with, for example, `\usesshorthands` or `\usesshorthands*`, described in Section 13.2.2 on page 304.

It is worth remembering here the hook mechanism provided by \LaTeX itself and described in detail in Appendix A.4 on page 671. Although with some limitations in a few cases, the hooks available in `\AddBabelHook` can also be used as the first argument of `\AddToHook`. As explained in the appendix, one advantage of this approach is that you can configure `babel` even before the package has been actually loaded.

`\addto\cmd{code}`

This command is a tool provided by `babel` allowing you to extend the definition of the control sequence `\cmd` with the \TeX code specified in `code`. The control sequence `\cmd` does not have to have been defined previously. The customary way to extend a language for years has been to modify directly `\extras<language>` and `\noextras<language>` with the help of this macro, but the more modern and robust interfaces based on hooks are preferable in most cases.

Language-specific tools

Some languages, like French, Spanish, or Hungarian, provide their own tools to tailor the style for specific needs, as an alternative to the use of `\languageattribute` commands. French and Hungarian understand a collection of key/value pairs, which are set with `\frenchsetup`, described in Section 13.3.4, and with the macro `\magyarOptions`, respectively. Spanish takes still another approach, using package options starting with the prefix `es-`.

13.6.2 Package level

This section is mainly for those who want to develop a language style or to better understand how `babel` works internally and explains briefly the basic concepts to define a language style.

Language definition files (file extension `.ldf`) have to conform to a number of conventions, because they complement the common shared code of `babel` provided in the file `babel.def` for producing language-dependent text strings. Similarly, to allow for language switching like the capability built into `babel`, certain rules apply. The basic working assumptions follow:

- Each language definition file `<language>.ldf` must define five macros, which are subsequently used to activate and deactivate the language-specific definitions. These macros are `\<language>hyphenmins`, `\captions<language>`, `\date<language>`, `\extras<language>`, and `\noextras<language>`, where `<language>` is either the name of the language definition file or the name of a `babel` package option. Some of these macros and their functions were discussed above.
- When a language definition file is loaded, it can define `\l@<language>` to be a variant (*dialect*) of `\language0` when `\l@<language>` is undefined.

- The language definition files must be written in a way that they can be read not just in the preamble of the document but also in the middle of document processing.

Hyphenating in several languages

Since T_EX version 3.0, hyphenation patterns for multiple languages can be used together. These patterns have to be managed somehow. In particular, the plainT_EX user has to know for which languages patterns have been loaded and to what values of the command sequence `\language` they correspond. The babel package abstracts from this low-level interface and manages this information by using an external file, `language.dat`, in which one records which languages have hyphenation patterns *and* in which files these patterns are stored. This configuration file is then processed¹ when the L^AT_EX format is built, except with LuaL^AT_EX, which loads it when the document is typeset. An example of such a file is shown here:

```
%%% Filename      : language.dat
%%% Description   : Instructions which pattern files to load.

english          ushyph.tex                % American English should be first
=usenglish
=USenglish
=american

dummylang        dummyhyph.tex             % For testing a new language
nohyphenation    zerohyph.tex              % Language with no patterns
ukenglish        loadhyph-en-gb.tex         % British English
=british
=UKenglish

german            loadhyph-de-1901.tex       % German language patterns
ngerman          loadhyph-de-1996.tex
swissgerman      loadhyph-de-ch-1901.tex
french           loadhyph-fr.tex            % French
=patois
=français

spanish          loadhyph-es.tex            % Spanish
=español

... many more languages ...
```

In most T_EX distributions this file is generated automatically² based on the available hyphenation patterns, which are coordinated by Arthur Reutenauer and Mojca

¹Make sure that you do not have several such files in your T_EX installation, because it is not always clear which of them is examined during the format generation. The author nearly got bitten during the book production when INI_TE_X picked up the system configuration file and not the specially prepared one containing all the patterns for the examples.

²This means that changing it directly is often not a good idea, because it might get overwritten on the next update. See your distribution documentation on how to do it safely; e.g., there might be a special file that is used instead (if it is present) or some other mechanism.

Miklavec as a separate package named `hyph-utf8`. Despite its name, it also provides versions for 8-bit font encodings.

Users should not be usually concerned with this configuration file, because the default settings are fine in most situations, but a short explanation on how it works follows in case you need to customize it. It can contain empty lines and comments, as well as lines that start with an equal (=) sign. Such a line instructs \LaTeX that the hyphenation patterns just processed should be made known under an alternative name. The first element on each line specifies the name of the language; it is followed by the name of the file containing the hyphenation patterns. An optional third entry can specify a hyphenation exception file in case the exceptions are stored in a separate file (e.g., `frhyphx.tex` in the previous example).

For each language in `language.dat`, the command `\l@<language>` is defined in the \LaTeX format (i.e., `\l@english` and so on). When the document is processed with such a format, `babel` checks for each language whether the command `\l@<language>` is defined and, if so, loads the corresponding hyphenation patterns; otherwise, it loads the patterns for the default language 0 (the one loaded first); for compatibility reasons this language should contain US-English hyphenation patterns.

```
initex latex.ltx
This is pdfTeX, Version 3.141592653-2.6-1.40.23 (TeX Live 2022/dev) (INITEX)
....
(/Library/texmf/tex/latex/base/latex.ltx
....
1141 hyphenation exceptions
Hyphenation trie of length 419877 has 8811 ops out of 35111
  143 for language 86
  110 for language 85
  138 for language 84
   7 for language 83

  53 for language 81
....
 137 for language 5
 424 for language 4
 432 for language 3
   2 for language 1
 181 for language 0
No pages of output.
```

The above output shows what `initex` loads into the format on the machine of the author: patterns for 87 different languages. The language with the number 2 corresponds to `nohyphenation` and is missing from the output because it contains no patterns. `Babel` uses these text strings (or their equivalents, specified preceded by an = sign in `language.dat`) to identify a language; with the package option `showlanguages`, a list of the hyphenation patterns loaded, with their numbers and names, is printed to the `.log` file.

A couple of tools for shorthands

Although mainly intended for shorthands, they can be useful in other contexts, too.

`\TextOrMath{text-code}{math-code}`

Recognizing that some shorthands declared in the language definition files have to be usable in both text and math modes, this macro allows you to specify the code to execute when in text mode (*text-code*) or when in math mode (*math-code*). Providing commands for use in text and math can have unwanted side effects, so this macro should be used with great care.

The `\TextOrMath` command is already provided by the \LaTeX format. The `babel` package offers the same functionality under the name `\textormath`, but if you want your text or commands to be processable with and without `babel` loaded, it is preferable to use the `CamelCase` command from the \LaTeX format.

`\allowhyphens \bbl@allowhyphens`

When \LaTeX cannot hyphenate a word properly by itself — for instance, because it is a compound word or because the word contains accented letters constructed using the `\accent` primitive, particularly when the `pdfTeX` is used — it needs a little help. This help involves making \LaTeX think it is dealing with two words, which appear as one word on the page. For this purpose `babel` provides the command `\allowhyphens`, which inserts an invisible horizontal skip, unless the current font encoding is T1.¹ In some cases one wants to insert this “help” unconditionally; for these cases `\bbl@allowhyphens` is available. This invisible skip has the effect of making \LaTeX think it is dealing with two words that can be hyphenated separately.

13.6.3 The package file

Instead of just retouching existing language styles in your documents or styles, you can opt for a more radical approach, namely, creating a completely new one. This is the way to go, of course, if there is no style at all for a certain language.

There are two ways to create a new style. The old good one is based on `.ldf` files, and the best way to define them, at least the basic structure, is with a graphical user interface, based on HTML and JavaScript, named “Language incubator”. This GUI is available on the `babel` GitHub repository (<https://github.com/latex3/babel>), under `tools`.

Note that many `.ldf` files use the concept of “dialect”, which is somewhat of a historical misnomer, because *lang* and *variant* are at the same level as far as `babel` is concerned, without any connotation indicating whether one or the other is the main language. The “dialect” paradigm comes in handy if you want to share hyphenation patterns between various languages. Moreover, if no hyphenation patterns are

¹In contrast to the OT1 encoding, the T1 encoding contains most accented characters as real glyphs so that the `\accent` primitive is almost never used.

preloaded in the format for the language *lang*, babel's default behavior is to define this language as a “dialect” of the default language (`\language0`).

Defining multiple languages or dialects in a single file is strongly discouraged. Although in the early days of babel this was a customary practice for optimization reasons, each language, dialect, or variant should be a language on its own, to follow the current trends for the handling of locales.

A more modern way to create languages is by means of `.ini` files, which has the advantage that the data are provided in a descriptive way. For example, the file for German (`babel-de.ini`) contains data such as:

```
[identification]
...
name.local = Deutsch
name.english = German
name.babel = german
name.polyglossia = german
tag.bcp47 = de
language.tag.bcp47 = de
tag.bcp47.likely = de-Latn-DE
tag.opentype = DEU
script.name = Latin
script.tag.bcp47 = Latn
script.tag.opentype = latn
encodings = T1 OT1 LY1
...
[captions]
preface = Vorwort
ref = Literatur
abstract = Zusammenfassung
bib = Literaturverzeichnis
...
[date.gregorian]
date.long = [d].[ ][MMMM] [y]
date.short = [dd].[MM].[yy]
months.wide.1 = Januar
months.wide.2 = Februar
...
[typography]
frenchspacing = yes
hyphenrules = ngerman
lefthyphenmin = 2
righthyphenmin = 2
...
```

This declarative approach helps to solve what is very likely one of the most common problems when creating a language style based on T_EX code, namely, that linguistic communities often have no T_EXnician among them to give a helping hand in developing such T_EX code. There are `.ini` templates for about 500 languages in the babel GitHub repository (under `locale-templates`), which can be used as a starting point.

Note that `.ini` files enforce the paradigm of separate locales for variants.

13.7 Other approaches

In general, the `babel` package does a good job of translating document element names and making text input somewhat more convenient. However, for several languages, individuals or local user groups have developed packages and versions of \TeX that cope with a given language on a deeper level—in particular, by better integrating the typographic traditions of the target language.

An example of such a package is `frenchle` [71], which was originally developed by Bernard Gaulle (1946–2007). Special customized versions of $(\text{\La})\text{\TeX}$ exist (e.g., Polish and Czech, distributed by the \TeX user groups GUST and $\text{\C}\text{\TeX}$ TUG, respectively).

Unicode engines

There are also some packages taking advantage of the features of $\text{\Xe}\text{\TeX}$ and $\text{\Lua}\text{\TeX}$. Besides those cited in Section 13.5, among others we have `xgreek` by Apostolos Syropoulos (CTAN: `macros/xetex/latex/xgreek`) and `arabluatex` by Robert Alessi (CTAN: `macros/luatex/latex/arabluatex`).

13.7.1 Complex languages with 8-bit engines

As explained above, the most convenient way to typeset languages with complex scripts is with $\text{\Xe}\text{\TeX}$ and $\text{\Lua}\text{\TeX}$. In the case that you still need to resort to 8-bit engines, here are some alternatives.

Several systems to handle Hebrew are available on CTAN in the directory `hebrew`.¹ In particular, `babel` offers an interface for Hebrew written by Boris Lavva, although fonts are not included, and you must download and install them separately. For Arabic there is the $\text{\Arab}\text{\TeX}$ system [104], developed by Klaus Lagally. This package extends the capabilities of $(\text{\La})\text{\TeX}$ to generate Arabic writing using an ASCII transliteration (CTAN: `arabic/arabtex`). For a truly Arabic style, Youssef Jabri has developed `arabi` (CTAN: `arabic/arabi`).

Serguei Dachian, Arnak Dalalyan, and Vardan Hakobian provide Armenian support (CTAN: `armenian/armtex`).

For the languages of the Indian subcontinent, most of the support is based on the work of Frans Velthuis. In particular, Anshuman Pandey developed packages for Bengali (`bengali` package and associated fonts on CTAN: `bengali/pandey`), Sanskrit (Anshuman Pandey’s `devnag` package on CTAN: `devanagari/velthuis`), and Gurmukhi (CTAN: `gurmukhi/pandey`).

Oliver Corff and Dorjpalam Dorj’s `montex` package can be used for typesetting languages using the Manju (Mongolian) scripts (CTAN: `mongolian/montex`).

Ethiopian language support, compatible with `babel`, is available through Berhanu Beyene, Manfred Kudlek, Olaf Kummer, and Jochen Metzinger’s `ethiop` package and fonts (CTAN: `ethiopia/ethiop`).

For Chinese, Japanese, and Korean (the so-called CJK scripts), one can use Werner Lemberg’s `CJK` package [119], which contains fonts and utilities (CTAN: `chinese/CJK`).

¹Prepend <https://www.ctan.org/tex-archive/language> in this and further references to obtain the full CTAN link, e.g., <https://www.ctan.org/tex-archive/language/hebrew>.

Another option for Chinese is CTEX, by Liam Huang, Qing Lee, Leo Liu, and several other contributors (CTAN: `chinese/ctex`).

13.7.2 Polyglossia

This package was originally developed as an alternative to `babel` for $X_{\text{K}}\text{T}_{\text{E}}\text{X}$ at a time when the former worked only with traditional $\text{T}_{\text{E}}\text{X}$. Although `babel` currently supports all languages `polyglossia` does, the latter might be preferable for a few languages, e.g., Korean, particularly when using $X_{\text{K}}\text{T}_{\text{E}}\text{X}$. In some other cases, there are some differences in the way a language is supported. However, the development of `babel` continues, and the situation should improve over time in the few languages where the use of `polyglossia` together with $X_{\text{K}}\text{T}_{\text{E}}\text{X}$ might be currently still preferable.

If you intend to move a document from `polyglossia` to `babel` or vice versa, bear in mind that even if the basic macros in `polyglossia` have the same names as in `babel`, their syntax and behavior slightly differs. For example, some languages are gathered under a single name, and you may need to select the *variant* you want. For this purpose, `\foreignlanguage` supports an optional argument in `polyglossia`. This concept does not exist in `babel`, where all locales are treated on an equal footing.

Furthermore, class options are not recognized, and languages are not loaded by means of package options, but with of couple of macros (`\setmainlanguage` and `\setotherlanguages`).

Unless you are in a special situation where a language or script is notably better supported by `polyglossia`, the recommendation is to use `babel` with all engines.

CHAPTER 14

Index Generation

14.1 Syntax of the index entries	345
14.2 <i>MakeIndex</i> — A program to sort and format indexes	350
14.3 <i>upmendex</i> — A Unicode-aware indexing program	364
14.4 <i>xindy</i> , <i>xindex</i> — Two other indexing programs	370
14.5 Enhancing the index with \LaTeX features	371

To find a topic of interest in a large document, book, or reference work, you usually turn to the table of contents or, more often, to the index. Therefore, an index is a very important part of a document, and most users' entry point to a source of information is precisely through a pointer in the index. You should, therefore, plan an index and develop it along with the main text [40]. For reasons of consistency, it is beneficial, with the technique discussed below, to use special commands in the text to always print a given keyword in the same way in the text and the index throughout the whole document.

This chapter first reviews the basic indexing commands provided by standard \LaTeX and explains which tools are available to help you build a well-thought-out index. The *\LaTeX Manual* does not contain a lot of information about the syntax of the `\index` entries. However, several articles in *TUGboat* deal with the question of generating an index with \TeX or \LaTeX . The syntax described in Section 14.1 is the one recognized by *MakeIndex* [39, 105] and the other indexing programs we discuss: *upmendex*, *xindy*, and *xindex*.

Section 14.2 describes how the *MakeIndex* processor is used. The interpretation of the input file and the format of the output file are controlled by style parameters. Section 14.2.4 lists these parameters and gives several simple examples to show how changing them influences the typeset result.

Section 14.3 presents *upmendex*, an Unicode-aware extension to *MakeIndex*. It is preferable to use this program whenever you have non-English documents or other special demands, such as the production of technical indexes.

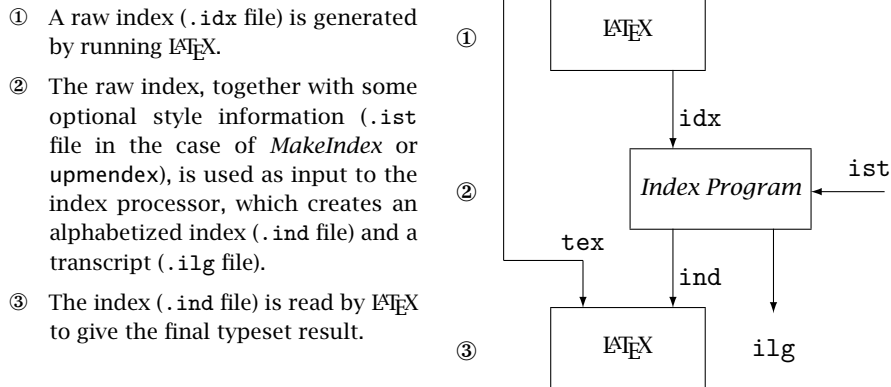

Figure 14.1: The sequential flow of index processing and the various auxiliary files used by \LaTeX and an external index processor, e.g., *MakeIndex*

In Section 14.4 we briefly discuss two further alternatives that you may come across. The final section describes several \LaTeX packages to enhance the index and to create multiple indexes such as those in the book you are reading.

* * *

The process of generating an index is shown schematically in Figure 14.1. The steps for generating an index with \LaTeX and *MakeIndex* are illustrated in this figure. The same flow is used with other index processors; only the configuration of the processors is done differently in some cases, i.e., not with .ist style files.

Figure 14.2 on the next page shows, with an example, the various steps involved in transforming an input file into a typeset index. It also shows, in somewhat more detail, which files are involved in the index-generating process. Figure 14.2(a) shows some occurrences of index commands ($\backslash\text{index}$) in the document source, with corresponding pages listed on the left. Figure 14.2(b) shows a raw index .idx file generated by \LaTeX . File extensions may differ when using multiple indexes or glossaries. After running the .idx file through the index processor, it becomes an alphabetized index .ind file with \LaTeX commands specifying a particular output format [Figure 14.2(c)]. The typeset result after formatting with \LaTeX is shown in Figure 14.2(d).

\LaTeX and *MakeIndex* (or *upmendex* or *xindex*), when employed together, use several markup conventions to help you control the precise format of the output. The *xindy* program has a *MakeIndex* compatibility mode that supports the same format. In Section 14.1, which describes the format of the $\backslash\text{index}$ command, we always use the default settings.

14.1 Syntax of the index entries

This section describes the default syntax used to generate index entries with \LaTeX and either *MakeIndex* or one of the other programs described in this chapter. Different levels of complexity are introduced progressively, showing, for each case, the input file and the generated typeset output.

Figures 14.3 and 14.4 on page 353 show the input and generated output of a small \LaTeX document, where various simple possibilities of the `\index` command are shown, together with the result of including the `showidx` package (see Section 14.5.2). To make the index entries consistent in these figures (see Section 14.1.7), the commands `\Com` and `\Prog` were defined and used. The index-generating environment `theindex` has been redefined to get the output on one page (Section 14.5.1 explains how this can be done).

After introducing the necessary `\index` commands in the document, we want to generate the index to be included once again in the \LaTeX document on a subsequent run. If the main file of a document is `main.tex`, for example, then the following changes should be made to that file:

- Include the `makeidx` package with a `\usepackage` command.
- Put a `\makeindex` command in the document preamble.

Generating the raw index

- Put a `\printindex` command where the index is to appear — usually at the end, right before the `\end{document}` command.

You then run \LaTeX on the entire document, causing it to generate the file `main.idx`, which we shall call the `.idx` file.

14.1.1 Simple index entries

Each `\index` command causes \LaTeX to write an entry in the `.idx` file. The following example shows some simple `\index` commands, together with the index entries that they produce. The page number refers to the page containing the text where the `\index` command appears. As shown in the example below, duplicate commands on the same page (such as `\index{stylistic}` on page 23) produce only one “23” in the index.

style, 14	Page iii: <code>\index{style}</code>
style , 16	Page xi: <code>\index{Stylist}</code>

stylistic, 23	<code>\index{stylistic}</code>
	Page 34: <code>\index{style file}</code>
	<code>\index{stylist}</code>

Spaces
can be harmful 

Pay particular attention to the way spaces are handled in this example. Spaces inside `\index` commands are written literally to the output `.idx` file and, by default, are treated as ordinary characters by *MakeIndex*, which places them in front of all letters. In the example above, look at the `style` entries on pages 14 and 16. The leading spaces are placed at the beginning of the index and on two different lines because the trailing blank on page 16 lengthens the string by one character. We end up with four different entries for the same term, an effect that was probably not desired.

It is therefore important to eliminate such spurious spaces from the `\index` commands when you use *MakeIndex*. Alternatively, you can specify the `-c` option when running the index processor. This option suppresses the effect of leading and trailing blanks (see Sections 14.2.2 and 14.3.1). We recommend always using this option; it should really have been the default.

Inconsistent
spelling 

Another frequently encountered error occurs when the same English word is spelled inconsistently with initial lowercase and uppercase letters (as with *Stylist* on page xi in the preceding example), leading to two different index entries.

Of course, this behavior is wanted in languages like German, where “Arm” (arm) and “arm” (poor) are really two completely different words.¹ In English, such spurious double entries should normally be eliminated.

¹As the joke goes: “Besser arm dran als Arm ab” (better poor than without an arm).

14.1.2 Generating subentries

A maximum of three levels of index entries (main, sub, and subsub entries) are available. To produce such entries, the argument of the `\index` command should contain both the main entries and subentries, separated by a `!` character. This character can be redefined in a style file (see Table 14.1 on page 357) if *MakeIndex* or *upmendex* is used as the index program.

box, 21	Page 3:	<code>\index{dimensions!rule!width}</code>
dimensions of, 33	Page 5:	<code>\index{box!parameters}</code>

rule	Page 21:	<code>\index{box}</code>
height, 12	Page 33:	<code>\index{box!dimensions of}</code>
width, 3		
table, 9		

14.1.3 Page ranges and cross-references

You can specify a page range by putting the command `\index{...|{}` at the beginning of the range and the command `\index{...|})}` at the end of the range. Page ranges should span a homogeneous numbering scheme (e.g., roman and arabic page numbers cannot fall within the same range). Note that *MakeIndex* and *upmendex* do the right thing when both ends of a page range fall on the same page or when another (individual) entry falls inside an active range.

You can also generate cross-reference index entries without page numbers by using the `see` encapsulator. Because the “see” entry does not print any page number, the commands `\index{...|see{...}}` can be placed anywhere in the input file *after* the `\begin{document}` command. For practical reasons, it is convenient to group all such cross-referencing commands in one place.

fonts	Page ii:	<code>\index{table {}</code>
Computer Modern, 13–25	Page xi:	<code>\index{table })}</code>
math, <i>see</i> math, fonts	Page 5:	<code>\index{fonts!OpenType {}</code>
OpenType, 5		<code>\index{fonts!OpenType })}</code> % same page
table, ii–xi, 14	Page 13:	<code>\index{fonts!Computer Modern {}</code>

	Page 17:	<code>\index{fonts!math see{math, fonts}}</code>
	Page 21:	<code>\index{fonts!Computer Modern}</code> % within range
	Page 25:	<code>\index{fonts!Computer Modern })}</code>

14.1.4 Controlling the presentation form

Sometimes you may want to sort an entry according to a key, while using a different visual representation for the typesetting, such as Greek letters, mathematical symbols, or specific typographic forms. This function is available with the syntax *key@visual*,

where *key* determines the alphabetical position and the string *visual* produces the typeset text of the entry.

delta, 14	Page 5:	<code>\index{ninety-five}</code>
δ , 23	Page 14:	<code>\index{delta}</code>
delta wing, 16	Page 16:	<code>\index{delta wing}</code>
flower , 19	Page 19:	<code>\index{flower@\textbf{flower}}</code>
ninety, 26	Page 23:	<code>\index{delta@\$\delta\$}</code>
xc, 28		<code>\index{tabular@\texttt{tabular} environment}</code>
ninety-five, 5	Page 26:	<code>\index{ninety}</code>
tabular environment, 23	Page 28:	<code>\index{ninety@xc}</code>

For some indexes, certain page numbers should be formatted specially. For example, an italic page number might indicate a primary reference, or an *n* after a page number might denote that the item appears in a footnote on that page. *MakeIndex* allows you to format an individual page number in any way you want by using the encapsulator syntax specified by the | character. What follows the | sign “encapsulates” or encloses the page number associated with the index entry. For instance, the command `\index{keyword|xxx}` produces a page number of the form `\xxx{n}`, where *n* is the page number in question. Similarly, the commands `\index{keyword|(xxx)}` and `\index{keyword|)xxx}` generate a page range of the form `\xxx{n-m}`.

Preexisting commands with one argument (like `\textit` in the example below) or user commands can be used to encapsulate the page numbers. As an example, a document containing the command definition

```
\newcommand\nn[1]{#1n}
```

would yield something like this:

tabular, ii, 21, 22n	Page ii:	<code>\index{tabular textbf}</code>
tabbing, 7, 34-37	Page 7:	<code>\index{tabbing}</code>
	Page 21:	<code>\index{tabular textit}</code>
	Page 22:	<code>\index{tabular nn}</code>
	Page 34:	<code>\index{tabbing (textit)}</code>
	Page 37:	<code>\index{tabbing)textit}</code>

The `\see` encapsulator is a special case of this facility, where the `\see` command is predefined by the `makeidx` package.

14.1.5 Printing special characters

To typeset one of the characters having a special meaning to *MakeIndex* or the other indexing programs (i.e., `!`, `"`, `@`, or `|`)¹ in the index, precede it with a `"` character. More precisely, any character is said to be quoted if it follows an unquoted `"` that is not part of a `\` command. The latter case allows for umlaut characters. Quoted `!`, `@`, `"`

¹As noted earlier, in *MakeIndex* and *upmendex* other characters can be substituted for the default ones and carry a special meaning. This behavior is explained on page 359.

, and | characters are treated like ordinary characters, losing their special meaning. The " preceding a quoted character is deleted before the entries are alphabetized.

@ sign, 2		<code>\index{bar@\texttt{\idxvert }} see{vertical bar}}</code>
, see vertical bar	Page 1:	<code>\index{quote (\verb+"")+}</code>
exclamation (!), 4		<code>\index{quote@\texttt{""} sign}</code>
Ah!, 5	Page 2:	<code>\index{atsign@\texttt{"@} sign}</code>
Mädchen, 3	Page 3:	<code>\index{maedchen@M{"{a}dchen}</code>
quote ("), 1	Page 4:	<code>\index{exclamation ("!")}</code>
" sign, 1	Page 5:	<code>\index{exclamation ("!")!Ah"!}</code>

14.1.6 Creating a glossary

LaTeX also has a `\glossary` command for making a glossary. The `\makeglossary` command produces a file with an extension of `.glo`, which is similar to the `.idx` file for the `\index` commands. LaTeX transforms the `\glossary` commands into `\glossaryentry` entries, just as it translates any `\index` commands into `\indexentry` entries.

MakeIndex can also handle these glossary commands, but you must change the value for some of the style file keywords, as shown in the style file `myglossary.ist`.

```
% MakeIndex style file myglossary.ist
keyword    "\\glossaryentry"          % keyword for glossary entry
preamble   "\\n \\begin{theglossary}\\n" % Begin glossary entries
postamble  "\\n\\n \\end{theglossary}\\n" % End glossary entries
```

In addition, you have to define a suitable `theglossary` environment.

14.1.7 Defining your own index commands

As was pointed out in the introduction, it is very important to use the same visual representation for identical names or commands throughout a complete document, including the index. You therefore can define user commands that always introduce similar constructs in the same way into the text and the index.

For example, you can define the command `\Index`, whose argument is entered at the same time in the text and in the index.

```
\newcommand\Index[1]{#1\index{#1}}
```

As explained in more detail below, you must be careful that the argument of such a command does not contain expandable material (typically control sequences) or spurious blanks. In general, for simple terms like single words, there is no problem, and this technique can be used. You can even go one step further and give a certain visual representation to the entry — for instance, typesetting it in a typewriter font.

```
\newcommand\indexttt[1]{\texttt{#1}\index{#1@\texttt{#1}}}
```

Finally, you can group certain terms by defining commands that have a generic meaning. For instance, L^AT_EX commands and program names could be treated with special commands, as in the following examples:

```
\newcommand\bs{\symbol{'134}} % print backslash in typewriter OT1/T1
\newcommand\Com[1]{\texttt{\bs#1}\index{#1@\texttt{\bs#1}}}
\newcommand\Prog[1]{\texttt{#1}\index{#1@\texttt{#1} program}}
```

The `\Com` command adds a backslash to the command's name in both text and index, simplifying the work of the typist. The `\bs` command definition is necessary, because `\textbackslash` would be substituted in an OT1 font encoding context,¹ as explained in Section 9.3.6 on page –I 670. At the same time, commands are ordered in the index by their names, with the “\” character being ignored during sorting. Similarly, the `\Prog` command provides a sort key not including the `\texttt` command, because otherwise the generated entry would be sorted into the wrong place in the index.

14.1.8 Special considerations

When an `\index` command is used directly in the text, its argument is expanded only when the index is typeset, not when the `.idx` file is written. However, when the `\index` command is contained in the argument of another command, characters with a special meaning to T_EX, such as `\`, must be properly protected against expansion. This problem is likely to arise when indexing items in a footnote or when using commands that put their argument in the text and enter it at the same time in the index (see the discussion in Section 14.1.7). Even in this case, robust commands can be placed in the “@” part of an entry, as in `\index{rose@\textit{rose}}`, but fragile commands must be protected with the `\protect` command.

As with every argument of a command, you need to have a matching number of braces. However, because `\index` allows special characters like `%` or `\` in its argument, if the command is used in the main text, the brace matching has an anomaly: braces in the commands `\{` and `\}` take part in the matching. Thus, you cannot write `\index{\{}` or something similar.

14.2 *MakeIndex*—A program to sort and format indexes

In the previous section we showed examples where we ran the *MakeIndex* program using its default settings. In this section we first take a closer look at the *MakeIndex* program and then discuss ways of changing its behavior. Nearly everything discussed in this section also applies to the *upmendex* program. The few places where there are differences between the two programs are explicitly marked.

¹In Unicode engines one needs to use `\textbackslash`, though.

14.2.1 Generating the formatted index

To generate the formatted index, you should run the *MakeIndex* program by typing the following command (where *main* is the name of the input file):

```
makeindex main.idx
```

This produces the file *main.ind*, which is called the *.ind* file here. If *MakeIndex* generated no error messages, you can now rerun \LaTeX on the document, and the index appears. (You can then remove the `\makeindex` command if you do not want to regenerate the index.) Page 355 describes what happens at this point if there are error messages.

In reading the index, you may discover additional mistakes. These should be corrected by changing the appropriate `\index` commands in the document and regenerating the *.ind* file (rerunning \LaTeX *before* and *after* the last step).

An example of running *MakeIndex* is shown below. The *.idx* file, *main.idx*, is generated by a first \LaTeX run on the input shown in Figure 14.3 on the next page. You can clearly see that two files are written — namely, the ordered *.ind* index file for use with \LaTeX , called *main.ind*, and the index *.ilg* log file, called *main.ilg*, which (in this case) contains the same text as the output on the terminal. If errors are encountered, then the latter file contains the line number and error message for each error in the input stream. Figure 14.4 on page 353 shows the result of the subsequent \LaTeX run. The example uses the *showidx* package for controlling the index (see Section 14.5.2).

```
makeindex main
This is makeindex, version 2.15 [TeX Live 2021] (kpathsea + Thai support).
Scanning input file main.idx...done (8 entries accepted, 0 rejected).
Sorting entries....done (24 comparisons).
Generating output file main.ind....done (19 lines written, 0 warnings).
Output written in main.ind.
Transcript written in main.ilg.
```

14.2.2 Detailed options of the *MakeIndex* program

The syntax of the options of the *MakeIndex* program are described below. Most options are also available for *upmendex*, a Unicode-aware extension of the program, discussed in Section 14.3 on page 364. If an option applies only to *MakeIndex*, then this is explicitly noted.

```
makeindex [-ciglqrLT] [-o ind] [-p no] [-s sty] [-t log] [idx0 idx1 ...]
```

- c Enable blank compression. By default, every blank counts in the index key. The `-c` option ignores leading and trailing blanks and tabs and compresses intermediate ones to a single space. We recommend always using this option.

```

\makeindex
\begin{document}
\section{Generating an Index}
Using the \textsf{showidx} package, users can see where they define
index entries.

Entries are entered into the index by the \Com{index} command. More
precisely, the argument of the \Com{index} command is written
literally into the auxiliary file \texttt{idx}. Note, however, that
information is actually written into that file only when the
\Com{makeindex} command was given in the document preamble.

\section{Preparing the Index}
In order to prepare the index for printing, the \texttt{idx} file has
to be transformed by an external program, like \MakeIndex{}. This
program writes the \texttt{ind} file.
\begin{verbatim}
makeindex filename
\end{verbatim}

\section{Printing the Index}\index{Final production run}
During the final production run of a document, the index can be
\index{include index}included by putting a \Com{printindex} command at
the position in the text where you want the index to appear (normally
at the end). This command will input the \texttt{ind} file prepared by
\MakeIndex{}, and \LaTeX{} will typeset the information.
\printindex
\end{document}

```

Figure 14.3: Example of \index commands and the showidx package

This file is run through \LaTeX once; then the index processor is executed, and \LaTeX is run a second time. The redefinition of the `theindex` environment is discussed in Section 14.5.1 on page 371.

1 Generating an Index

Using the `showidx` package, users can see where they define index entries.

Entries are entered into the index by the `\index` command. More precisely, the argument of the `\index` command is written literally into the auxiliary file `idx`. Note, however, that information is actually written into that file only when the `\makeindex` command was given in the document preamble.

```
index@\index
index@\index
makeindex@\makeindex
makeindex@\makeindex
program
Final
production
run
include index
printindex@\printindex
makeindex@\makeindex
program
```

2 Preparing the Index

In order to prepare the index for printing, the `idx` file has to be transformed by an external program, like `makeindex`. This program writes the `ind` file.

```
makeindex filename
```

3 Printing the Index

During the final production run of a document, the index can be included by putting a `\printindex` command at the position in the text where you want the index to appear (normally at the end). This command will input the `ind` file prepared by `makeindex`, and \LaTeX will typeset the information.

Figure 14.4: Printing the index and the output of the `showidx` option

This figure shows the index generated from the example input in Figure 14.3. All index entries are shown in the margin, so it is easy to check for errors or duplications.

- i Use standard input (`stdin`) as the input file. When this option is specified and `-o` is not, output is written to standard output (`stdout`, the default output stream).
- g Employ German word ordering in the index, following the rules given in German standard DIN5007. In this case the normal precedence rule of *MakeIndex* for word ordering (symbols, numbers, uppercase letters, lowercase letters) is replaced by the German word ordering (symbols, lowercase letters, uppercase letters, numbers). Additionally, this option enables *MakeIndex* to recognize the German T_EX commands "a, "o, "u, and "s as *ae*, *oe*, *ue*, and *ss*, respectively, for sorting purposes. The quote character must be redefined in a style file (see page 359); otherwise, you get an error message, and *MakeIndex* aborts. Note that not all versions of *MakeIndex* recognize this option.
Note that this option has a different use in *upmendex*, which has a different way to enable German sorting rules.
- l Use letter ordering. The default is word ordering. In word ordering, a space comes before any letter in the alphabet. In letter ordering, spaces are ignored. For example, the index terms "point in space" and "pointing" are alphabetized differently in letter and word ordering.
- o *ind* Take *ind* as the output index file. By default, the file name base of the first input file *idx0* concatenated with the extension `.ind` is used as the output file name.
- p *no* Set the starting page number of the output index file to *no*. This option is useful when the index file is to be formatted separately. Other than pure numbers, three special cases are allowed for *no*: any, odd, and even. In these special cases, the starting page number is determined by retrieving the last page number from the `.log` file of the last L^AT_EX run. The `.log` file name is determined by concatenating the file name base of the first raw index file (*idx0*) with the extension `.log`. The last source page is obtained by searching backward in the log file for the first instance of a number included in square brackets. If a page number is missing or if the `.log` file is not found, no attempt is made to set the starting page number. The meaning of each of the three special cases follows:
 - any The starting page is the last source page number plus one.
 - odd The starting page is the first odd page following the last source page number.
 - even The starting page is the first even page following the last source page number.
- q Operate in quiet mode. No messages are sent to the error output stream (`stderr`). By default, progress and error messages are sent to `stderr` as well as the transcript file. The `-q` option disables the `stderr` messages.

- r Disable implicit page range formation. By default, three or more successive pages are automatically abbreviated as a range (e.g., 1-5). The -r option disables this default, making explicit range operators the only way to create page ranges.
- s *sty* Take *sty* as the style file. There is no default for the style file name. The environment variable INDEXSTYLE defines where the style file resides.
- t *log* Take *log* as the transcript file. By default, the file name base of the first input file *idx0* concatenated with the extension .ilg is used as the transcript file name.
- L Sort the index based on the current locale settings of the computer. This option is not available in all versions of *MakeIndex* and not available with *upmendex*, which uses style keywords to define the sorting behavior.
- T Special support for Thai documents. This option is not available in all versions of *MakeIndex* and not offered by *upmendex*.

14.2.3 Error and warning messages

MakeIndex displays on the terminal how many lines were read and written and how many errors were found. Messages that identify errors are written in the transcript file, which, by default, has the extension .ilg. *MakeIndex* can produce error messages when it is reading the .idx file or when it is writing the .ind file. Each error message identifies the nature of the error and the number of the line where the error occurred in the file. In the reading phase, the line numbers in the error messages refer to the positions in the .idx file being read.

Errors in the reading phase

Extra ‘!’ at position ...

The \index command’s argument has more than two unquoted ! characters. Perhaps some of them should be quoted.

Extra ‘@’ at position ...

The \index command argument has two or more unquoted @ characters with no intervening !. Perhaps one of the @ characters should be quoted.

Extra ‘|’ at position ...

The \index command’s argument has more than one unquoted | character. Perhaps the extras should be quoted.

Illegal null field

The \index command argument does not make sense because some string is null that should not be. The command \index{!funny} produces this error, because it specifies a subentry “funny” with no entry. Similarly, the command \index{@funny} is incorrect, because it specifies a null string for sorting.

Argument ... too long (max 1024)

The document contained an \index command with a very long argument. You probably forgot the right brace that should delimit the argument.

Errors in the writing phase In the writing phase, line numbers in the error messages refer to the positions in the .idx file being written.

Unmatched range opening operator

An `\index{...|}` command has no matching `\index{...|})` command following it. The “...” in the two commands must be completely identical.

Unmatched range closing operator

An `\index{...|})` command has no matching `\index{...|}` command preceding it.

Extra range opening operator

Two `\index{...|}` commands appear in the document with no intervening command `\index{...|})`.

Inconsistent page encapsulator ... within range

MakeIndex has been instructed to include a page range for an entry, and a single page number within that range is formatted differently — for example, by having an `\index{cat|see{animals}}` command between an `\index{cat|}` command and an `\index{cat|})` command.

Conflicting entries

MakeIndex thinks it has been instructed to print the same page number twice in two different ways. For example, the command sequences `\index{lion|see{...}}` and `\index{lion}` appear on the same page.

MakeIndex can produce a variety of other error messages indicating that something is seriously wrong with the .idx file. If you get such an error, it probably means that the .idx file was corrupted in some way. If \LaTeX did not generate any errors when it created the .idx file, then it is highly unlikely to have produced a bad .idx file. If, nevertheless, this does happen, you should examine the .idx file to establish what went wrong.

In some cases the program produces warnings instead of error messages, e.g., when it encounters data in the style file that it does not recognize. This may or may not be an issue; for example, at some point in the past a few keywords got renamed, and to cater for this some style files supply both versions, and thus one then generates such a warning. But it may also indicate that you misspelled a keyword. Thus, if the behavior is not as you expect, check the .ilg file for such warnings.

14.2.4 Customizing the index

MakeIndex ensures that the formats of the input and output files do not have to be fixed, but they can be adapted to the needs of a specific application. To achieve this format independence, the *MakeIndex* program is driven by a style file, usually characterized with a file extension of .ist (see also Figure 14.1 on page 344). This file consists of a series of keyword/value pairs. These keywords can be divided into input and output style parameters. Table 14.1 on the facing page describes the various keywords and their default values for the programming of the input file. This table shows, for instance, how to modify the index-level separator (level, with ! as the

<i>Keyword</i>	<i>Default Value</i>	<i>Description</i>
<code>keyword</code> ^(s)	<code>"\\indexentry"</code>	Command telling <i>MakeIndex</i> that its argument is an index entry.
<code>arg_open</code> ^(c)	<code>'{'</code>	Argument opening delimiter.
<code>arg_close</code> ^(c)	<code>'}'</code>	Argument closing delimiter.
<code>range_open</code> ^(c)	<code>' ('</code>	Opening delimiter indicating the beginning of an explicit page range.
<code>range_close</code> ^(c)	<code>') '</code>	Closing delimiter indicating the end of an explicit page range.
<code>level</code> ^(c)	<code>' ! '</code>	Delimiter denoting a new level of subitem.
<code>actual</code> ^(c)	<code>' @ '</code>	Symbol separating the sort key from the “actual” representation in the index file.
<code>encap</code> ^(c)	<code>' '</code>	Symbol indicating that the rest of the argument list is to be used as an encapsulating command for the page number.
<code>quote</code> ^(c)	<code>' " '</code>	Symbol that escapes the character following it.
<code>escape</code> ^(c)	<code>' \\ '</code>	Symbol without any special meaning unless it is followed by the quote character, in which case that character loses its special function and both characters are printed. This is included because <code>\</code> is the umlaut accent in T _E X. The two symbols <code>quote</code> and <code>escape</code> must be distinct.
<code>page_compositor</code> ^(s)	<code>" - "</code>	Composite page delimiter.

^(s) Attribute of type *string*; ^(c) attribute of type *char* (enclose in double or single quotes, respectively)

Table 14.1: Input style parameters for *MakeIndex* and *upmendex*

default character value). Table 14.2 on the next page describes the various keywords and their default values for steering the translation of the input information into L^AT_EX commands. This table explains how to define the way the various levels are formatted (using the `item` series of keywords). Examples show in more detail how these input and output keywords can be used in practice. *MakeIndex* style files use Unix string syntax, so you must enter `\\` to get a single `\` in the output.

In the following sections we show how, by making just a few changes to the values of the default settings of the parameters controlling the index, you can customize the index.

A stand-alone index

The example style `mybook.ist` (shown below) defines a stand-alone index for a book, where “stand-alone” means that it can be formatted independently of the main source. Such a stand-alone index can be useful if the input text of the book is frozen (the page numbers do no longer change) and you want only to reformat the index.

```
% MakeIndex style file mybook.ist
preamble  "\\documentclass[12pt]{book} \n\n \\begin{document} \n
          \\begin{theindex}\n"
postamble "\\n\n\\end{theindex} \n \\end{document}\n"
```

<i>Keyword</i>	<i>Default Value</i>	<i>Description</i>
<i>Context</i>		
<code>preamble</code> ^(s)	<code>"\\begin{theindex}\\n"</code>	Preamble command preceding the index.
<code>postamble</code> ^(s)	<code>"\\n\\n\\end{theindex}\\n"</code>	Postamble command following the index.
<i>Starting Page</i>		
<code>setpage_prefix</code> ^(s)	<code>"\\n\\setcounter{page}{"</code>	Prefix for the command setting the page.
<code>setpage_suffix</code> ^(s)	<code>"}\\n"</code>	Suffix for the command setting the page.
<i>New Group</i>		
<code>group_skip</code> ^(s)	<code>"\\n\\n\\indexspace\\n"</code>	Vertical space inserted before a new group.
<i>Entry Separators</i>		
<code>item_0</code> ^(s)	<code>"\\n\\item "</code>	Command to be inserted in front of a level 0 entry.
<code>item_1</code> ^(s)	<code>"\\n \\subitem "</code>	Ditto for a level 1 entry starting at level ≥ 1 .
<code>item_2</code> ^(s)	<code>"\\n \\subsubitem "</code>	Ditto for a level 2 entry starting at level ≥ 2 .
<code>item_01</code> ^(s)	<code>"\\n \\subitem "</code>	Command before a level 1 entry starting at level 0.
<code>item_12</code> ^(s)	<code>"\\n \\subsubitem "</code>	Ditto for a level 2 entry starting at level 1.
<code>item_x1</code> ^(s)	<code>"\\n \\subitem "</code>	Command to be inserted in front of a level 1 entry when the parent level has no page numbers.
<code>item_x2</code> ^(s)	<code>"\\n \\subsubitem "</code>	Ditto for a level 2 entry.
<i>Page Delimiters</i>		
<code>delim_0</code> ^(s)	<code>", "</code>	Delimiter between entry and page number(s) at level 0.
<code>delim_1</code> ^(s)	<code>", "</code>	Ditto at level 1.
<code>delim_2</code> ^(s)	<code>", "</code>	Ditto at level 2.
<code>delim_n</code> ^(s)	<code>", "</code>	Delimiter between different page numbers.
<code>delim_r</code> ^(s)	<code>"--"</code>	Designator for a page range.
<code>delim_t</code> ^(s)	<code>" "</code>	Terminator of the page number list.
<code>suffix_2p</code> ^(s)	<i>not set by default</i>	Suffix as replacement for a two-page range, e.g., "f".
<code>suffix_3p</code> ^(s)	<i>not set by default</i>	Suffix as replacement for a three-page range, e.g., "ff".
<code>suffix_mp</code> ^(s)	<i>not set by default</i>	Ditto for a multi-page range (three or more pages).
<i>Page Encapsulators</i>		
<code>encap_prefix</code> ^(s)	<code>"\\"</code>	Prefix to be used in front of a page encapsulator.
<code>encap_infix</code> ^(s)	<code>"{"</code>	Infix to be used for a page encapsulator.
<code>encap_suffix</code> ^(s)	<code>"}"</code>	Suffix to be used for a page encapsulator.
<i>Page Number Precedence</i>		
<code>page_precedence</code> ^(s)	<code>"rnaRA"</code>	a, A are lower-, uppercase alphabetic; n is numeric; r and R are lower- and uppercase roman.
<i>Line Wrapping</i>		
<code>line_max</code> ⁽ⁿ⁾	72	Maximum length of an output line.
<code>indent_space</code> ^(s)	<code>"\\t\\t"</code>	Indentation commands for wrapped lines.
<code>indent_length</code> ⁽ⁿ⁾	16	Length of indentation for wrapped lines.

"\\n" and "\\t" are a new line and a tab; ^(s) attribute of type *string*; ⁽ⁿ⁾ attribute of type *number*

Table 14.2: Output style parameters for *MakeIndex* and *upmendex*

Keyword	Default Value	Description
<i>Group headings — Control & Presentation</i>		
<code>headings_flag</code> ⁽ⁿ⁾	0	Controls all group headings: if zero, nothing is inserted before each group. Otherwise, a value >0 (<0) includes an uppercase (lowercase) instance of the symbol characterizing the new letter group, prefixed with <code>heading_prefix</code> and appending <code>heading_suffix</code> . For numbers and symbols special headings are inserted.
<code>heading_prefix</code> ^(s)	" "	Prefix for a new group heading.
<code>heading_suffix</code> ^(s)	" "	Suffix for a new group heading.
<i>Group headings — Symbols</i>		
<code>symhead_positive</code> ^(s)	"Symbols"	Heading for symbols, inserted if <code>headings_flag</code> is positive.
<code>symhead_negative</code> ^(s)	"symbols"	Heading for symbols, inserted if <code>headings_flag</code> is negative.
<i>Group headings — Numbers (restrictions^(*) with upmindex)</i>		
<code>numhead_positive</code> ^(s)	"Numbers"	Heading for numbers, inserted if <code>headings_flag</code> is positive.
<code>numhead_negative</code> ^(s)	"numbers"	Heading for numbers, inserted if <code>headings_flag</code> is negative.

^(s) Attribute of type *string*; ⁽ⁿ⁾ attribute of type *number*

^(*) In upmindex both keys are ignored by default; see Table 14.4 on page 367 for how to enable them

Table 14.3: Group headings style parameters for *MakeIndex* and upmindex

Assuming that the raw index commands are in the file `mybook.idx`, then you can call *MakeIndex* specifying the style file's name:

```
makeindex -s mybook.ist -o mybookindex.tex mybook
```

We have used a nondefault output file name to avoid clobbering the source output (presumably `mybook.pdf`). If the index is in file `mybook.ind`, then its typeset output also ends up in `mybook.pdf`, thus overwriting the `.pdf` file for the main document.

Moreover, if you want the page numbers for the index to come out correctly, then you can specify the page number where the index has to start (e.g., 181 in the example below):

```
makeindex -s mybook.ist -o mybookindex.tex -p 181 mybook
```

MakeIndex can also read the L^AT_EX log file `mybook.log` to find the page number to be used for the index (see the `-p` option described on page 354).

Changing the “special characters”

The next example shows how you can change the interpretation of special characters in the input file. To do so, you must specify the new special characters in a style file (for instance, `myinchar.ist` shown below). Using Table 14.1 on page 357, in

the following example we change the @ character (see page 347) to =, the sublevel indicator ! (see page 347) to >, and the quotation character " (see page 348) to ! (the default sublevel indicator):

```
% MakeIndex style file myinchar.ist
actual '='      % = instead of default @
quote '!'      % !
level '>'      % >
               !
```

The next example makes use of these declarations and shows some index entries and the resulting output. It also assumes the `ngerman` option of the `babel` package; i.e., the double quote character (") is used as a shortcut for the umlaut construct \".

This shows another feature of the ordering algorithm used by *MakeIndex*; namely, the constructs " and \" are considered to be different entries (Br"ucke and Br\"ucke, M"adchen and M\"adchen, although in the latter case the key entry was identical, Maedchen). Therefore, it is important to use the same input convention throughout a complete document.

" sign, 1	Page 1: \index{\texttt{"} sign}
= sign, 2	Page 2: \index{\texttt{@} sign}
@ sign, 2	Page 2: \index{\texttt{!=} sign}
Brücke, 5	Page 3: \index{Maedchen=M"{a}dchen}
Brücke, V	Page c: \index{Maedchen=M"adchen}
Brücke, v	Page v: \index{Bruecke=Br"ucke}
dimensions	Page 5: \index{Br"ucke}
rule	Page V: \index{Br\"ucke}
width, 3	Page 3: \index{dimensions>rule>width}
exclamation (!), 4	Page 4: \index{exclamation (!!)}
Ah!, 5	Page 5: \index{exclamation (!!)>Ah!!}
Mädchen, c	
Mädchen, 3	

Note, however, that for languages such as German it is much nicer to be able to enter the index entries as UTF-8 strings; e.g., Brücke and Mädchen. This is possible if you use `upmindex` instead of *MakeIndex*.

Changing the output format of the index

You can also personalize the output format of the index. The first thing that we could try is to build an index with a nice, big letter between each letter group. This is achieved with the style `myhead.ist`, as shown below (see Table 14.3 on the previous page for more details on the various keywords available for headings):

```
% MakeIndex style file myhead.ist
headings_flag      1                % Turn on headings (uppercase)
heading_prefix     "{\\bfseries\\hfil " % Insert in front of letter
heading_suffix     "\\hfil}\\nopagebreak\\n" % Append after letter
```

This then gives a result such as the following:

Symbols	Page 2:	<code>\index{\texttt{"@} sign}</code>
@ sign, 2	Page 3:	<code>\index{dimensions!rule!width}</code>
B	Page 5:	<code>\index{box!parameters}</code>
box, 21	Page 9:	<code>\index{dimensions!table}</code>
dimensions of, 33	Page 12:	<code>\index{dimensions!rule!height}</code>
parameters, 5	Page 17:	<code>\index{dimensions!figure}</code>
D	Page 21:	<code>\index{box}</code>
dimensions	Page 33:	<code>\index{box!dimensions of}</code>
figure, 17		<code>\index{rule!depth}</code>
rule	Page 41:	<code>\index{rule!width}</code>
height, 12	Page 48:	<code>\index{rule!depth}</code>
width, 3		
table, 9		
R		
rule		
depth, 33, 48		
width, 41		

You could go a bit further and right-adjust the page numbers, putting in dots between the entry and the page number to guide the eye. This effect can be achieved by adding the following declarations:

```
% MakeIndex style file myright.ist
delim_0 "\\dotfill "
delim_1 "\\dotfill "
delim_2 "\\dotfill "
```

The result for the same input would then be this:

@ sign	2	Page 2:	<code>\index{\texttt{"@} sign}</code>
box	21	Page 3:	<code>\index{dimensions!rule!width}</code>
dimensions of	33	Page 5:	<code>\index{box!parameters}</code>
parameters	5	Page 9:	<code>\index{dimensions!table}</code>
dimensions		Page 12:	<code>\index{dimensions!rule!height}</code>
figure	17	Page 17:	<code>\index{dimensions!figure}</code>
rule		Page 21:	<code>\index{box}</code>
height	12	Page 33:	<code>\index{box!dimensions of}</code>
width	3		<code>\index{rule!depth}</code>
table	9	Page 41:	<code>\index{rule!width}</code>
rule		Page 48:	<code>\index{rule!depth}</code>
depth	33, 48		
width	41		

The \LaTeX command `\dotfill` can be replaced by fancier commands, but the underlying principle remains the same.

Treating funny page numbers

As described earlier, *MakeIndex* accepts five basic kinds of page numbers: digits, uppercase and lowercase alphabetic, and uppercase and lowercase roman numerals. You can also build composed page numbers. The separator character for composed page numbers is controlled by the *MakeIndex* keyword `page_compositor`; the default is the hyphen character (-), as noted in Table 14.1 on page 357. The precedence of ordering for the various kinds of page numbers is given by the keyword `page_precedence`; the default is `rRnaA`, as noted in Table 14.2 on page 358.

Problems with
letters as page
numbers

Let us start with an example involving simple page numbers. Assume the pages with numbers `ii`, `iv`, `1`, `2`, `5`, `a`, `c`, `A`, `C`, `II`, and `IV` contain an `\index` command with the word `style`. With the default `page_precedence` of `rRnaA` this would be typeset in the index as shown below. The `c` and `C` entries are considered to be roman numerals, rather than alphabetic characters, so we get:

style, ii, iv, c, II, IV, C, 1, 2, 5, a, A

This order can be changed by using the `page_precedence` keyword to `"rnAaR"`. Running *MakeIndex* on the same index entries now yields:

style, ii, iv, c, 1, 2, 5, A, a, II, IV, C

As you see, the letters like `C` are still interpreted as roman numerals. Thus, as long as *MakeIndex* offers no possibility to modify this behavior, it is ill adapted for pages numbered by letters — either one accepts a potentially incorrect order in the page references or one has to manually correct the final index.

Composed page
numbers

The situation looks somewhat different if composed page numbers are used, e.g., page numbers like `"B-3"` (where `"B"` is the appendix number and `"3"` the page number within this appendix). In this case `C` is interpreted as a letter, but `I` is still considered a roman numeral. Thus, in this setting you can have up to eight appendices before you run into trouble.

Suppose that the unsorted index entries show the page numbers `C--3`, `1--1`, `D--1--1`, `B--7`, `F--3--5`, `2--2`, `D--2--3`, `A--1`, `B--5`, and `A--2`. If this raw index is processed with *MakeIndex*, it results in an empty formatted index and a lot of error messages, because the default page separator is a single hyphen. However, by setting the `page_compositor` keyword to `"--"`, you can process this raw index successfully and get the following result:

style, 1-1, 2-2, A-1, A-2, B-5, B-7, C-3, D-1-1, D-2-3, F-3-5

Because *MakeIndex* supports only a single page separator, more complex page numbering schemes involving several different page separators (such as `A-4.1`) cannot be processed by the program.

14.2.5 Pitfalls to watch out for

The `\index` command tries to write its argument unmodified to the `.idx` file whenever possible. This behavior has a number of consequences, because \LaTeX 's way of dealing with the problem of preventing expansion is not always successful.

If the index text contains commands, as in `\index{\Prog}`, the entry is likely wrongly sorted, because if used in the main text this entry is sorted under the sort key `\Prog` (with the special character `\` as the starting sort character) regardless of the definition of the `\Prog` command. On the other hand, if it is used in some argument of another command, `\Prog` expands before it is written to the `.idx` file; the placement in the index then depends on the expansion of `\Prog`. The same thing happens when you use `\index` inside your own definitions. That is, all commands inside the index argument are expanded (except when they are robust or preceded by `\protect`).¹

For sorting, *MakeIndex* assumes that pages numbered with lowercase roman numerals precede those numbered with arabic numerals, which in turn precede those numbered with the lowercase alphabet, uppercase roman numerals, and finally the uppercase alphabet. This precedence order can be changed (see the entry `page_precedence` in Table 14.2 on page 358).

MakeIndex places symbols (i.e., patterns starting with a nonalphanumeric character) before numbers and before alphabetic entries in the output. Symbols are sorted according to their ASCII values. For word sorting, uppercase and lowercase are considered the same, but for identical words, the uppercase variant precedes the lowercase one. Numbers are sorted in numeric order. The *upmendex* program offers you some customization possibilities to alter the sort order of scripts and symbols.

Spaces are treated as ordinary characters when alphabetizing the entries and when deciding whether two entries are the same (see also the example on page 346). Thus, if “`␣`” denotes a space character, the commands `\index{cat}`, `\index{␣cat}`, and `\index{cat␣}` produce three separate entries. All three entries look similar when printed. Likewise, `\index{a␣space}` and `\index{a␣␣space}` produce two different entries that look exactly the same in the output. For this reason it is important to check for spurious spaces by being careful when splitting the argument of an `\index` command across lines in the input file. The *MakeIndex* option `-c` turns off that behavior and trims leading and trailing white space, compressing all white space within to one blank. We recommend that you use it all the time.

MakeIndex assumes that the input data in the `.idx` files contains only ASCII data. These days *T_EX* writes UTF-8 files by default. This is fine because ASCII is a subset of UTF-8, but if the data contains UTF-8 characters outside of ASCII, they will be incorrectly read and processed by *MakeIndex* on a byte-by-byte basis resulting in incorrect sorting or worse — this is where the program *upmendex* comes into play.

The *upmendex* program, on the other hand, expects its input data to be encoded in UTF-8 and not in any legacy 8-bit encoding. The only indexing program that can handle such legacy file encodings successfully is *xindy*.

The programs *MakeIndex* and *upmendex* have similar but not identical options. Thus, if you change your workflow from one to the other, make sure that everything behaves as it should. Some options in *upmendex* have extended semantics, which is usually fine, but `-g`, for example, has a totally different meaning in both programs.

Consider always using the `-c` option

Use *MakeIndex* only with ASCII input

Use *upmendex* only with UTF-8 input

Program options are not exactly identical

¹The *index* package (see Section 14.5.3) uses a different approach that prevents expansion in *all* cases, which is arguably the better approach.

14.3 upmindex — A Unicode-aware indexing program

The program `upmindex` by TAKUJI Tanaka is an index processor that is Unicode-aware. It is fully compatible with *MakeIndex*'s input syntax and supports, except for a few minor differences, all configuration options described in the previous sections — any differences are explicitly discussed below.

The program was originally developed under the name `mindex` to offer a *MakeIndex* variant with tailored support for the Japanese language. For this, a number of new configuration options got added. The `upmindex` program extends this further, and by delegating the sorting to the International Components for Unicode (ICU) library, many different sorting schemes, based on languages or use case requirements, can be realized. For these features additional style keywords are available.

Because most of what was discussed for *MakeIndex* in the previous sections also applies to `upmindex`, we describe only the differences and extensions made by the program in detail below and otherwise refer to the *MakeIndex* documentation.

14.3.1 Options, warnings, and errors of the program

The `upmindex` program is called in the same way as *MakeIndex* and offers a comparable set of options.

```
upmindex [-cigflqr] [-d dic] [-o ind] [-p no] [-s sty] [-t log] [idx ...]
```

Options shared with *MakeIndex* are only briefly listed here; more details on them are found in Section 14.2.2 on page 351. The *MakeIndex* options `-L` and `-T` are not supported by `upmindex`, and the option `-g` has a new meaning that is discussed below.

Unsupported
MakeIndex options

Options shared with
MakeIndex

- `-c` Enable blank compression.
- `-i` Use standard input (`stdin`) as the input file.
- `-l` Use letter instead of word ordering.
- `-o ind` Take *ind* as the output index file.
- `-p no` Set the starting page number of the output index file to *no*.
- `-q` Operate in quiet mode.
- `-r` Disable implicit page range formation.
- `-s sty` Take *sty* as the style file.
- `-t log` Take *log* as the transcript file.

All other options are available only with `upmindex` and are needed if your index contains Japanese words that need sorting. However, as explained later, `-d` and `-f` are also useful with other scripts.

- d *dic* Employ *dic* as a dictionary file. Japanese Kanjis have one or more “reading”, and in order to sort them, the reading to be used for sorting needs to be specified. This is done in dictionary files containing lines of the form

<index entry> *<key>*

which allows you to write `\index{<index entry>}` to achieve the same effect as when writing `\index{<key>@<index entry>}`. For correct sorting in Japanese the *key* should be written in Hiragana or Katakana script. The dictionary is consulted only if the *index entry* cannot be sorted automatically; i.e., you cannot use it to make arbitrary substitutions.

- f Force upmindex to output characters unchanged if it cannot determine a sort key and cannot find a dictionary entry. For example, indexing a “€” character would normally result in an error stopping the processing, because upmindex would not know how to sort it. This option would allow it to continue.
- g By default Japanese index entries are grouped by their component phonemes. This ordering is called a *gojūon* (lit. fifty sounds) table and consists of 48 kana because the table is not fully filled. When using the -g option, the entries are grouped into only five groups (the columns of the *gojūon* table corresponding to the vowels a, i, u, e, and o, in that order). In *MakeIndex* this option is used to implement German language sorting instead.

Like *MakeIndex*, the upmindex program displays information on the terminal and writes error and warnings in the transcript file. See Section 14.2.3 on page 355 for details on the error messages that are largely identical in both programs.

A number of messages are specific to upmindex, e.g., messages related to reading dictionary files (option -d), and there are a few new additional errors and warnings related to the extensions made for processing the full range of Unicode characters and the sorting with the ICU library. We describe here only those that one is more likely to encounter when generating an index for languages other than Japanese and that are not obvious from their message text.

Error: *<entry>* is no entry in dictionary file in ...

upmindex does not know how to make a sort key for the index *<entry>*, and it has not found an dictionary entry for it either. This is a hard error, and processing stops. Either you have to provide a dictionary file containing an appropriate entry line or you have to use the option -f to force the program to continue despite this error. This happens, for example, if the index entry contains symbols, such as † or €, unless you tell upmindex explicitly how to handle them.

Warning: [ICU] U_USING_DEFAULT_WARNING for locale *<locale>*

The *<locale>* specified in `icu_locale` in the style file has no effect because it is already covered by the default ICU sorting rules. For example, specifying `de` (for German) would have this effect. It can be safely ignored, but it means that the

specification was not necessary, in contrast to requesting, say, German phonebook ordering, which would be done with `de@collation=phonebook`.

Warning: Illegal input for `icu_attributes` (`<key>:<value>`)

The `<key>` and/or `<value>` specified for an ICU attribute in `icu_attributes` is not recognized. Check if there is a misspelling.

Warning: Sort key "`<key1>`" is different from previous key "`<key2>`" for same index "`<entry>`" in ...

There have been two or more index entries for `<entry>`, using different sort keys, e.g., "`abc@F00`" and "`xyz@F00`". This is most likely a mistake in the input source, because it results in "`F00`" appearing in two different places in the index. This issue is checked for only by `upmindex`, but not detected by `MakeIndex`.

14.3.2 Customizing the index with `upmindex`

Just like `MakeIndex`, the input and output behavior of the `upmindex` program can be customized through a style file (in fact with `upmindex` you can even supply several style files by repeatedly using the `-s` option).

The input style parameters are the same as for `MakeIndex` and are listed in Table 14.1 on page 357. The output style parameters listed in Tables 14.2 and 14.3 on pages 358–359 are also available. Consequently, all customization possibilities discussed in Section 14.2.4 on page 356 are also applicable for `upmindex`.

However, `upmindex` extends this set in several directions; the additional output parameters are shown in Table 14.4 on the next page. Below we discuss features that are available only when these parameters are used.

Adjusting the sorting to rules of a specific language or script

When it comes to sorting, different languages often have their own conventions, for example, whether to sort characters with diacritics under the base character or treat them as separate characters, etc. This makes the production of a properly sorted index challenging.

One of the main advantages of `upmindex` is therefore its ability to use the ICU services for sorting, which means that in many cases you have to specify only which "locale" should be used for sorting and let the ICU library worry about the rest. This locale is specified in the style file with the keyword `icu_locale`.

For example, if you have index entries for the words "Amme", "Apfel", "Äpfel", and "Axel", then the default sorting for English, German, and several other languages would be the following:

Amme, 1	Page 1: <code>\index{Amme}</code>
Apfel, 2	Page 2: <code>\index{Apfel}</code>
Äpfel, 2	Page 2: <code>\index{Äpfel}</code>
Axel, 3	Page 3: <code>\index{Axel}</code>

That is, the "Ä" is directly sorted after "A" within the letter group for A.

Keyword	Default Value	Description
<i>Sorting</i>		
<code>icu_locale</code> ^(s)	""	The locale defining the basic sorting order for the index. Supported values are given in Table 14.5 on page 369.
<code>icu_attributes</code> ^(s)	""	ICU attributes to further tailor the sorting. Supported values are given in Table 14.6 on page 369.
<code>icu_rules</code> ^(s)	""	ICU rules to alter individual character sorting order.
<i>Character/Script order</i>		
<code>character_order</code> ^(s)	"SNLGCJKHDT"	The output order of scripts and symbols. The letters represent Symbols, Numbers, Latin, Greek, Cyrillic, Japanese Kana, Korean Hangul, Hanja, Devanagari, and Thai script.
<i>Japanese specifics</i>		
<code>letter_head</code> ⁽ⁿ⁾	1	Use Katakana (default) or Hiragana (2) for Japanese Kana heading letters.
<code>priority</code> ⁽ⁿ⁾	0	If nonzero, add one space between Japanese and non-Japanese text in an index entry while sorting.
<i>Script heading characters</i>		
<code>devangari_head</code> , <code>hangul_head</code> , <code>hanzi_head</code> , <code>kana_head</code> , <code>thai_head</code> , ...		Strings holding characters to be used as individual heading characters (one after the other) in front of entry groups within the script. For details, see the program documentation.
<i>Group heading for Symbols and Numbers</i>		
<code>symbol_flag</code> ⁽ⁿ⁾	0	By Japanese conventions, symbols and numbers are sorted as a single group. If <code>symbol_flag</code> has the value 0, then <code>symhead_positive</code> or <code>symhead_negative</code> is used for the heading text of the group consisting of both symbols and numbers. If it is 1, then the value of <code>symbol</code> is used instead, and if it is set to 2, the program behaves like <i>MakeIndex</i> , and symbols and numbers get their own groups.
<code>symbol</code> ^(s)	""	Heading text when <code>symbol_flag</code> is set to 1.

^(s) Attribute of type *string*; ⁽ⁿ⁾ attribute of type *number*

Table 14.4: Additional output style parameters for upmindex

However, if you apply the Swedish locale (`icu_locale="sv"`) in the style file, you get a different result because now “Ä” forms its own letter group.

Amme, 1	Page 1: \index{Amme}
Apfel, 2	Page 2: \index{Apfel}
Axel, 3	Page 2: \index{Äpfel}
Äpfel, 2	Page 3: \index{Axel}

Even within a language, sorting rules may differ based on the application; e.g., in Germany, sorting in phonebooks usually interprets the Umlaut “Ä” as “Ae”.

This can in some cases be catered for by embellishing the locale information, i.e., `icu_locale_ de@collation=phonebook` after which the output shows “Äpfel” as the first entry, because it is sorted as “Aepfel”:

Äpfel, 2	Page 1: \index{Amme}
Amme, 1	Page 2: \index{Apfel}
Apfel, 2	Page 2: \index{Äpfel}
Axel, 3	Page 3: \index{Axel}

Many languages are supported without the need for explicitly setting a locale

It is important to note that the locale used by `upmendex` is independent of the locale set on your operating system — only the value in `icu_locale` matters, and if not set, the ICU “root” order default applies. The latter is adequate for a large number of languages, among them Dutch, English, French, German, Italian, Portugese, etc. The list of supported locales that have special requirements is already quite large, but it is expected to grow even further. Table 14.5 on the facing page lists languages that need special locale settings as well as those that have supported variants for sorting; e.g., for German you do not need a locale setting unless you want phonebook sorting, so only the latter is listed in the table.

Tailoring the sorting with attributes

Besides setting the locale to influence the sorting, it is possible to tailor it by applying ICU attributes. These attributes can alter broader aspects, for example, whether lowercase characters should be sorted before or after uppercase characters. Supported attributes and their values are listed in Table 14.6 on the next page. You apply them by combining the attribute name with its value and assign this to `icu_attributes` in the style file. To set more than one attribute, separate them with a blank. Below we give a few examples of changes you may want to apply; for more details study the ICU documentation [193].

Sort numbers numerically

Digits in index entries are normally sorted as strings such that “V128” is placed before “V64”. However, you may want to see them sorted by their numeric value, which can be achieved with

```
icu_attributes      "numeric-ordering:on"
```

after which “V64” comes first, because 64 is numerically smaller than 128.

Lowercase first!

If entries differ only in the case of their characters, the uppercase entries are usually placed first. You can alter that by using

```
icu_attributes      "case-first:lower-first"
```

French collation rules

In most languages, sorting is based on comparing strings from start to end, and if words differ only in some diacritics, then the first such difference determines the order. However, in some French dictionary traditions it is the last diacritics that are used for the ordering. For example, normally the words “cote”, “coté”, “côte”, and “côté” would be sorted in exactly this order, but after specifying

```
icu_attributes      "french-collation:on"
```

two words change their places, so we end up with “cote”, “côte”, “coté”, “côté”.

<i>language</i>	<i>locale(s)</i>	<i>language</i>	<i>locale(s)</i>
<i>Latin scripts</i>			
Albanian	sq	Norwegian	nb, nn, no
Azerbaijan	az	Polish	pl
Catalan	ca	Romanian	ro
Croatian	hr, hr@collation=search	Serbian	sr-Latn,
Czech	cs, cs@collation=search		sr-Latn@collation=search
Danish	da	Slovak	sk, sk@collation=search
Esperanto	eo	Slovenian	sl
Finnish	fi	Spanish	es, es@collation=traditional,
Galician	gl		es@collation=search
German	de@collation=phonebook	Swedish	sv
Hungarian	hu	Turkish	tr
Lithuanian	lt	Vietnamese	vi
<i>Greek script</i>			
Greek	el		
<i>Cyrillic scripts</i>			
Belarusian	be	Serbian	sr
Bulgarian	bg	Ukraine	uk
Russian	ru		
<i>CJK scripts</i>			
Japanese	ja, ja@collation=unihan	Chinese	zh, zh@collation=unihan,
Korean	ko, ko@collation=search,		zh@collation=stroke,
	ko@collation=unihan		zh@collation=zhuyin

Many languages are directly supported by the default root sort order and therefore do not need an explicit setting. If you specify any of them, e.g., `de` (German), you get a warning that the default is used.

Table 14.5: Supported ICU locale settings for `icu_locale`

<i>Attribute</i>	<i>Values</i>	<i>Attribute</i>	<i>Values</i>
<code>alternate</code>	<code>:shifted, :non-ignorable</code>	<code>normalization-mode</code>	<code>:on, :off</code>
<code>case-first</code>	<code>:off, :upper-first, :lower-first</code>	<code>numeric-ordering</code>	<code>:on, :off</code>
<code>case-level</code>	<code>:on, :off</code>	<code>french-collation</code>	<code>:on, :off</code>
<code>strength</code>	<code>:primary, :secondary, :tertiary, :quaternary, :identical</code>		

Table 14.6: ICU attributes supported by upmendex

*Ignore punctuations
while sorting*

Perhaps a little less peculiar is the question of whether punctuation characters should play a rôle in sorting; e.g., how do you sort “high-level” and “higher”? By default “high-level” would come first because “-” gets compared to “e”. If you want to ignore punctuation characters while sorting, you can specify

```
icu_attributes          "strength:tertiary alternate:shifted"
```

after which “higher” comes first, because now “e” is compared to “l”.

*Ignore diacritics
while sorting*

The `strength` attribute used above determines to what level of detail the sorting algorithm considers characters as being different; for example, the following

```
icu_attributes          "strength:primary"
```

would ignore diacritics.

There is also the possibility of specifying granular rules for individual character combinations that overwrite default sorting rules given through the locale. Such rules are then specified with the `icu_rules` keyword in the style file. The syntax and specification are rather technical and complicated and not something a user would normally undertake, so they are not described here. See the documentation on the Internet [193] if you are curious.

*Order of different
scripts in the index*

Given that `upmendex` supports different scripts and an index may contain several of them in parallel, there is the question how these should be ordered relative to each other; e.g., should Latin entries come before or after Cyrillic ones, etc. To adjust this order, you can use the keyword `character_order` in the style file. It expects a string of letters where each letter stands for a particular script or group of characters. For example, “SNLCG” would output first symbols and numbers, then Latin entries, then Cyrillic ones, and finally Greek entries. Note that you can separate symbol and number groups only if you additionally set `symbol_flag` to 2.

14.4 xindy, xindex — Two other indexing programs

There are other indexing programs, and in passing we like to mention two of them here. The first one is `xindy` by Roger Kehr and Joachim Schrod, which has been one of the early contenders as a replacement for *MakeIndex*. It avoids several of *MakeIndex*’s limits, especially for generating indexes in non-English languages. Being available for more than two decades, it was adapted to support many languages and scripts. However, most of this support was developed prior to the widespread use of Unicode, and while the program can handle Unicode to some extent, many aspects of it show that its original design assumes 8-bit codepages. The program and its support files are distributed as part of most T_EX distributions, so there is no issue with continuing usage in existing projects, if the program’s capabilities are sufficient for them. However, for new projects we recommend using `upmendex` or (with some caveats) `xindex`.

The program `xindex` is a recent development by Herbert Voß. It is a Unicode-aware index processor written in Lua that is compatible with the default syntax of *MakeIndex*.

However, it does not yet support the customization possibilities of *MakeIndex* and its .ist style files. Similar to upmendex, it can be directed to use the ICU algorithms and (some of) their tailoring features but uses a different syntax to enable this. At the moment the feature and script support is still somewhat limited, but because it is actively being developed, we might see further features in the future.

14.5 Enhancing the index with L^AT_EX features

This section describes L^AT_EX's support for index creation. It presents possibilities to modify the index layout and to produce multiple indexes.

14.5.1 Modifying the layout

You can redefine the environment `theindex`, which by default is used to print the index. The layout of the `theindex` environment and the definition of the `\item`, `\subitem`, and `\subsubitem` commands are defined in the class files `article`, `book`, and `report`. In the `book` class you can find the following definitions:

```
\newenvironment{theindex}
  {\@restonecoltrue\if@twocolumn\@restonecolfalse\fi
   \columnseprule \z@ \columnsep 35\p@
   \twocolumn[\@makeschapterhead{\indexname}]\%
   \@mkboth{\MakeUppercase\indexname}{\MakeUppercase\indexname}%
   \thispagestyle{plain}\parindent\z@ \parskip\z@ \@plus .3\p@\relax
   \let\item\@idxitem}
  {\if@restonecol\onecolumn\else\clearpage\fi}
\newcommand\@idxitem {\par\hangindent 40\p@}
\newcommand\subitem {\par\hangindent 40\p@ \hspace*{20\p@}}
\newcommand\subsubitem{\par\hangindent 40\p@ \hspace*{30\p@}}
```

Although this is programmed in a fairly low-level internal language, you can probably decipher what it sets up. First it tests for two-column mode and saves the result. Then it sets some spacing parameters, resets the page style to `plain`, and calls `\twocolumn`. Finally, it changes `\item` to execute `\@idxitem`, which produces a paragraph with a hanging indentation of 40 points. A higher-level reimplementaion (using `ifthen`) might perhaps look as follows:

```
\renewenvironment{theindex}
  {\ifthenelse{\boolean{@twocolumn}}{\setboolean{@restonecol}{false}}{\%
   \setboolean{@restonecol}{true}}\%
   \setlength\columnseprule{0pt}\setlength\columnsep{35pt}\%
   \twocolumn[\chapter*{\indexname}]\%
   \markboth{\MakeUppercase\indexname}{\MakeUppercase\indexname}%
   \setlength\parindent{0pt}\setlength\parskip{0pt plus 0.3pt}\%
   \thispagestyle{plain}\ExpandArgs{Nc}\RenewCommandCopy\item{\@idxitem}}
  {\ifthenelse{\boolean{@restonecol}}{\onecolumn}{\clearpage}}
```

Adjusting this definition allows you to make smaller modifications, such as changing the page style or the column separation.

You can also make an index in three rather than two columns. To do so, you can use the `multicol` package and the `multicols` environment:

```
\renewenvironment{theindex}{%
  \begin{multicols}{3}[\chapter*{\indexname}] [10\baselineskip]%
  \addcontentsline{toc}{chapter}{\indexname}%
  \setlength\parindent{0pt}\pagestyle{plain}%
  \ExpandArgs{Nc}\RenewCommandCopy{\item}{\@idxitem}}%
{\end{multicols}}
```

We require at least ten lines of free space on the current page; otherwise, we want the index to start on a new page. In addition to generating a title at the top, we enter the heading as a “Chapter” in the table of contents (`.toc`) and change the page style to `plain`. Then the `\item` command is redefined to cope with index entries (see above), and the entries themselves are typeset in three columns using the `multicols` environment.

14.5.2 `showidx`, `repeatindex`, `tocbibind`, `indxcite` — Little helpers

Several useful little \LaTeX packages exist to support index creation. A selection is listed in this section, but by browsing through the Internet resources discussed in Section C.4 on page 789, you can probably find additional ones.

*Show index entries
in margin*

The package `showidx` (by Leslie Lamport) can help you improve the entries in the index and locate possible problems. It shows all `\index` commands in the margin of the printed page. Figure 14.4 on page 353 shows the result of including the `showidx` package.

*Handle page breaks
gracefully*

The package `repeatindex` (by Harald Harders) repeats the main item of an index if a page or column break occurs within a list of subitems. This helps the reader correctly identify to which main item a subitem belongs.

*Table of contents
support*

The package `tocbibind` (by Peter Wilson) can be used to add the table of contents itself, the bibliography, and the index to the *Table of Contents* listing. See page I 56 for more information on this package.

*Automatic author
index*

The package `indxcite` (by James Ashton) automatically generates an author index based on citations made using \BibTeX . This type of functionality is also available with the bibliography packages `natbib`, `jurabib`, and `biblatex`, all of which are described in detail in Chapter 16.

14.5.3 `index` — Producing multiple indexes

The `index` package (written by David Jones) augments \LaTeX ’s indexing mechanism in several areas:

- Multiple indexes are supported.
- A two-stage process is used for creating the raw index files (such as the default `.idx` file) similar to that used to create the `.toc` file. First the index entries are

written to the `.aux` file, and then they are copied to the `.idx` file at the end of the run. With this approach, if you have a large document consisting of several included files (using the `\include` command), you no longer lose the index if you format only part of the document with `\includeonly`. Note, however, that this makes the creation of a chapter index more difficult.

- A starred form of the `\index` command is introduced. In addition to entering its argument in the index, it typesets the argument in the running text.
- To simplify typing, the `\shortindexingon` command activates a shorthand notation. Now you can type `^{foo}` for `\index{foo}` and `_{foo}` for `\index*{foo}`. These shorthand notations are turned off with the `\shortindexingoff` command. Because the underscore and circumflex characters have special meanings inside math mode, this shorthand notation is unavailable there.
- The package includes the functionality of the `showidx` package. The command `\proofmodetrue` enables the printing of index entries in the margins. You can customize the size and style of the font used in the margin with the `\indexproofstyle` command, which takes a font definition as its argument (e.g., `\indexproofstyle{\footnotesize\itshape}`).
- The argument of `\index` is never expanded when the index package is used. In standard L^AT_EX, using `\index{\command}` sometimes writes the expansion of `\command` to the `.idx` file (see Section 14.2.5 on page 362). With the index package, `\command` itself is always written to the `.idx` file. While this is helpful in most cases, macro authors can be bitten by this behavior. In Section 14.1.7, we recommended that you define commands that automatically add index entries. Such commands often expect that `\index` expands its parameter, and they may not work when you use the index package. Be careful and check the results of the automatic indexing — this is best practice anyway.

You can declare new indexes with the `\newindex` command. The command `\renewindex`, which has an identical syntax, is used to redefine existing indexes.

`\newindex{tag}{raw-ext}{proc-ext}{indextitle}`

The first argument, *tag*, is a short identifier used to refer to the index. In particular, the commands `\index` and `\printindex` are redefined to take an optional argument — namely, the tag of the index to which you are referring. If this optional argument is absent, the index with the tag “default” is used, which corresponds to the usual index. The second argument, *raw-ext*, is the extension of the raw index file to which L^AT_EX should write the unprocessed entries for this index (for the default index it is `.idx`). The third argument, *proc-ext*, is the extension of the index file in which L^AT_EX expects to find the processed index (for the default index it is `.ind`). The fourth argument, *indextitle*, is the title that L^AT_EX prints at the beginning of the index.

As an example we show the setup used to produce this book. The preamble included the following setting:

```
\RequirePackage{index}
\proofmodetrue           % while proofing the index entries
\newindex{xauthor}{adx}{and}{People}
\newindex{xcmds}{cdx}{cnd}{Index of Commands and Concepts}
```

In the back matter, printing of the index was done with the following lines:

```
\printindex[xcmds] \printindex[xauthor]
```

For each generated raw index file (e.g., `tlc3.adx` for the list of authors) we ran *MakeIndex* to produce the corresponding formatted index file for \LaTeX :

```
makeindex -o tlc3.and -t tlc3.alg tlc3.adx
```

While all of these tools help to get the correct page numbers in the index, the real difficulty persists: choosing useful index entries for your readers. This problem you still have to solve (if you are lucky, with help).

In fact, the index for the second edition of this book [145], as well as the indexes for the *LaTeX Graphics Companion* [55], was created by a professional indexer, Richard Evans of Infodex Indexing Services in Raleigh, North Carolina. Dick worked closely with me to produce comprehensive indexes that help you, the reader, find not only the names of things (packages, programs, commands, and so on) but also the tasks, concepts, and ideas described in the books. Let him tell you (from his FAQ):

Question: Why do I need an indexer? Can't the computer create an index?

Answer: To exactly the same degree that a word processor can write the book.

Indexes are creative works, requiring human intellect and analysis.

\LaTeX can process the indexing markup, but only a human indexer can decide what needs to be marked up. My sincere thanks to Dick for his excellent work and the teaching he delivered while working with him.

* * *

Unfortunately, Dick was unable to help me with this edition, as was initially planned. However, I learned a lot during our joint work on the other books, and with this knowledge and the good basis of terms selected for the previous edition, I am fairly confident that we have been able to deliver a useful result to you.

In this process I received invaluable help from Keith Harrison, who went through all pages of the book, identified new concepts worth indexing, and verified existing entries — a big thank you to him.

CHAPTER 15

Bibliography Generation

15.1 The standard \LaTeX bibliography environment.	376
15.2 The biber and \BibTeX programs	378
15.3 The \BibTeX database format.	380
15.4 Using \BibTeX or biber to produce the bibliography.	409
15.5 On-line bibliographies	413
15.6 Bibliography database management tools	414
15.7 Formatting the bibliography with styles	418

While a table of contents (see Section 2.3) and an index (discussed in Chapter 14) make it easier to navigate through a book, the presence of bibliographic references should allow you to verify the sources and to probe further subjects you consider interesting. To make this possible, the references should be precise and lead to the relevant work with a minimum of effort.

There exist many ways to format bibliographies, and different fields of scholarly activities have developed very precise rules in this area. An interesting overview of Anglo-Saxon practices can be found in the chapter on bibliographies in *The Chicago Manual of Style* [40]. Normally, authors must follow the rules laid out by their publisher. Therefore, one of the more important tasks when submitting a book or an article for publication is to generate the bibliographic reference list according to those rules.

Traditional ways of composing such lists by hand, without the systematic help of computers, are plagued with the following problems:

- Citations and references, particularly in a document with contributions from many authors, are hard to make consistent. Difficulties arise, such as variations in the use of full forenames versus abbreviations (with or without periods); italicization or quoting of titles; spelling “ed.”, “Ed.”, or “Editor”; and the various forms of journal volume number.

- A bibliography laid out in one style (e.g., alphabetic by author and year) is extremely hard to convert to another (e.g., numeric citation order) if requested by a publisher.
- It is difficult to maintain one large database of bibliographic references that can be reused in different documents.

In the present chapter we concentrate on the formatting of reference lists and bibliographies, and we discuss possibilities for managing collections of bibliographic references in databases. The chapter is heavily based on the `BibTeX` program, written by Oren Patashnik, and the `biber` program written by François Charette and now maintained by Philip Kime, which both integrate well with `LATEX`. In Chapter 16 we are then mainly concerned with the citation of sources within the text.

We start by showing how a bibliography can be created manually in `LATEX`. Because the standard environment is also used in the output of most `BibTeX` styles, this prepares the ground for the `BibTeX` workflow. We then introduce the two programs. This is followed by a detailed introduction to the database format¹ used to specify bibliographical data in a suitable form for processing with `BibTeX` or `biber`. We continue with a description of how to produce bibliographic input files for `LATEX` from these databases.

Instead of collecting your own bibliographical data, there is also the possibility of drawing information from various online sources that offer such data in `BibTeX` format. Some of them are introduced in Section 15.5.

Having collected data for `BibTeX` databases, the next natural step is to look for tools that help in managing such databases. Section 15.6 offers tools of various flavors for this task, ranging from command-line utilities to GUI-based programs for various platforms.

Finally, in Section 15.7 we return to the task of typesetting a bibliography and discuss how different `BibTeX` and `biblatex` styles can be used to produce different bibliography layouts from the same input. Because there may not be a suitable style for a particular set of layout requirements available, Section 15.7.2 discusses how to generate customized styles using the `custom-bib` package without the need for any `BibTeX` style programming. How to create or adapt styles for `biblatex` is discussed in Chapter 16 where we review that package in detail.

15.1 The standard `LATEX` bibliography environment

The standard `LATEX` environment for generating a list of references or a bibliography is called `thebibliography`. It is not defined by `LATEX` itself but by the document class, so the layout can vary. In its default implementation in the standard classes, it automatically generates an appropriate heading and implements a vertical list structure in which every publication is represented as a separate item. It also creates

¹Due to its origin, the format is commonly referred to as the `BibTeX` database format, even if used with `biber`. Thus, if you read “`BibTeX` database format” in the remainder of this chapter, it refers to the format usable by either of the programs.

for every item a label to allow referencing it in the document. The `thebibliography` environment can be created manually, but it is also used in the output of most Bib_TE_X styles. It is not used by the `bibtex` package, which typesets bibliographies with its own command, `\printbibliography`.

The different traditions regarding how such sources are then referred to in a document and how to produce such citations with L^AT_EX is the topic of Chapter 16; here citation commands are mentioned only as far as necessary to understand how they affect the bibliography.

```
\begin{thebibliography}{\widest-label}
\bibitem[label1]{cite-key1} bibliographic information
\bibitem[label2]{cite-key2} bibliographic information
...
\end{thebibliography}
```

The *widest-label* argument is used to determine the right amount of indentation for individual items. If the works are numbered sequentially, for example, it should contain the number of items.

Individual publications are introduced with a `\bibitem` command. Its mandatory argument is a unique cross-reference *cite-key* that is used to refer to this publication in the text of the document. For this purpose L^AT_EX offers the `\cite` command, which takes such a *cite-key* as its argument. Its precise syntax is described in Section 16.2.1 on page 475.

The optional argument defines the textual representation that is used in the citation and as the *label* in the list. If this argument is not specified, the publications are numbered with arabic numerals by default. Within a bibliographic entry the command `\newblock` may be used to separate major blocks of information. Depending on the layout produced by the document class, it may result in a normal space, may result in some extra space, or might start a new line.

The text of the heading is produced — depending on the class — by either the command `\bibname` or `\refname`. A language package, such as `babel`, localizes such commands and changes to them should be done by using the methods described in Chapter 13.

Producing a large bibliography manually in this way is clearly a tedious and difficult task, and the result is normally not reusable, because nearly all journals and publishers have their own house styles with different formatting requirements. For this reason it is generally better to use programs, such as `BIBTEX` or `biber`, that generate ready-to-use `LATEX` input from a database of bibliographical information. This is discussed in the next section.

*Order by first
citation done
manually*

Note that the references are typeset and numbered in the order in which they appear in the bibliography. Thus, if you produce the bibliography manually, numbering and sorting the entries into the correct order becomes your task, which is especially difficult if they should be ordered by first reference in the text instead of alphabetically. In contrast, when using `BIBTEX` or `biber`, either order can be achieved automatically.

*Handling the
requirement to use a
thebibliography
environment
explicitly*

Some journals provide templates in which you are required to provide the reference list as explicit `\bibitems` in a `thebibliography` environment. When generating the bibliography with `BIBTEX`, this can be easily achieved by copying the final `.bbl` content into your document before submitting. However, when using `biblatex/biber`, this is not possible. In this case, the `biblatex2bibitem` package by Nikolai Avdeev can be of some help. Its usage is simple: load the package and issue `\printbibitembibliography` at the end of the document. This then typesets at this point a source representation of the `thebibliography` environment, which can be copied and pasted from the PDF into the source file intended for the journal. However, please note that when using the engine `pdfTEX`, you need to ensure that your document uses `\usepackage[T1]{fontenc}` so that you get real accented characters into the output — with the default `OT1` encoding, cut and paste goes horribly wrong otherwise.

Copying from a PDF is not fool-proof even then, and the result should be checked for faulty characters and missing spaces. But it can save you from having to manually retype a possibly lengthy reference list.

15.2 The `biber` and `BIBTEX` programs

The `BIBTEX` program was designed by Oren Patashnik to provide a flexible solution to the problem of automatically generating bibliography lists conforming to different layout styles. It automatically detects the citation requests in a `LATEX` document (by scanning its `.aux` file or files), selects the needed bibliographical information from one or more specified databases, and formats it according to a specified layout style. Its output is a file containing the bibliography listing as `LATEX` code that is automatically loaded and used by `LATEX` on the following run. Section 15.4 on page 409 discusses the interface between the two programs in some detail.

At the time of this book's writing `BIBTEX` was available as version 0.99d, but if you look into the second edition of this book (a decade back), you find that it already talks about version 0.99c. Version 0.99a probably dates back to 1986. In other words, the program has been kept stable for a very long period of time. As a consequence, the `BIBTEX` database format is very well established in the `LATEX` world (and in fact even far beyond), with many people having numerous citation entries collected over the

years. Thus, it comes as no surprise that all development that happened in the last decades is based on that format as a standard.

Due to its age and origins BibTeX is 7-bit, ASCII based. Although it is able to handle foreign characters, its functionality in this respect is rather limited. It can sort only ASCII characters and has trouble generating initials for non-ASCII characters. For this reason non-ASCII characters usually have to be input with macros as described on page 398. Most BibTeX styles then purify the sort key by converting some special control sequences like `\oe` to letters while ignoring all others and then removing all nonalphanumeric characters. This means that “Ælk” is sorted as `aelk`, but “Ålk”, “Älk”, and “Alk” all sort as `alk`.

This lack of support for Unicode and the sorting rules of languages different from English has led to the development of alternatives. In the rest of this section we briefly survey a variant of BibTeX and introduce the relatively new biber program.

15.2.1 bibtex8 — An 8-bit reimplementaion of BibTeX

The BibTeX8 program written by Niel Kempson and Alejandro Aguilar-Sierra is an 8-bit reimplementaion of BibTeX with the ability to specify sorting order information. This allows you to store your BibTeX database entries in an 8-bit code page and to use the `inputenc` package in your L^AT_EX document (see Sections 9.5.4 and 9.9.3).

While this is an improvement over BibTeX, the restriction to an 8-bit code page and therefore the missing support of the de facto standard encoding UTF-8 makes it nowadays useful only in isolated cases.

The BibTeX8 program offers command-line options that allow you to enlarge its internal tables. In 1995, when the first release of the program was written, standard BibTeX had only small, hardwired internal tables, making it impossible to typeset, say, a bibliography listing with several hundred citations. These days most installations use higher customizable defaults (e.g., 20000 citations in T_EX Live) so that the flexibility of BibTeX8 in this respect is seldom needed. But in case a particular job hits one of the limits and emits a message like “Sorry -- you’ve exceeded BibTeX’s...”, you can use BibTeX8 with a suitable command-line setting to get around the problem or with BibTeX edit the `texmf.cnf` configuration file to alter the default setting.

There are other extensions of the original BibTeX program, but we found none that works reliably, which is why we suggest using biber and biblatex if the basic capabilities of BibTeX or BibTeX8 are not sufficient for your needs.

15.2.2 biber — A Unicode-aware bibliography processor

In 2009 François Charette released the first version of a successor for BibTeX called biber, whose development was driven by the increasing demand of tools that support out-of-the-box Unicode, UTF-8, and various languages and scripts. In the following years biber was improved in parallel to the package biblatex, and both are now closely coupled. Using biber requires using biblatex as the bibliography package in L^AT_EX, and while biblatex still can be used with BibTeX, this is not recommended as many of its

new and sophisticated features work only with `biber`. All `biblatex` examples of this book have been processed with `biber` as the backend processor.

`biber` is written in `perl`, i.e., in a far more powerful programming language than the language used in the `.bst` style files of `BibTeX`. Among other features, `biber` deals with the full range of UTF-8 and sorts in a completely customizable manner using, when available, Unicode Common Locale Data Repository (CLDR) collation tailoring.

The `biber` program can be used in two modes: standard and tool mode. In the standard mode, which is used when you create bibliographic input for `LaTeX`, it expects as its main argument a `.bcf` control file — the extension can be omitted. The output is then a file with the same basename and the extension `.bbl`. In tool mode, which is triggered by the option `--tool`, the argument is a `.bib` file, and the result is a new `.bib` file with `_bibertool` appended to the basename. In both modes, the name of the output file can be changed with the option `--output-file`. `biber` accepts a large number of command-line options to adjust the output, which you can inspect if you call `biber` with the `--help` option or by consulting the documentation [78]. So, for example, the following converts all field names in a `.bib` file to lowercase:

```
biber --tool --output-fieldcase=lower <file>.bib
```

The next command replaces the field name `journaltitle` with `journal`:

```
biber --tool --output-field-replace=journaltitle:journal <file>.bib
```

Finally, the following can be used to nicely align the fields in the `.bib` file:

```
biber --tool --output-align <file>.bib
```

*Adaption of the
editor needed*

Most modern editors and `TeX`-workflows contain scripts, buttons, or menus to call the bibliography processor. Their settings must be changed if `biber` should be used instead of `BibTeX`. Instructions for various cases can be found on the Internet or, if the editor is already `biber`-aware, in the documentation of the editor. The settings can be checked by looking in the `.blg` file after a compilation. It contains messages of the bibliography processor, and `biber` announces itself in the first line:

```
[0] Config.pm:311> INFO - This is Biber 2.17
```

15.3 The `BibTeX` database format

As remarked on before, the bibliographic database format used by all programs was originally designed for `BibTeX` and is therefore commonly referred to as the “`BibTeX` database format”. Such a `BibTeX` database is a plain-text file with the extension `.bib` that contains bibliographical entries internally structured as key/value pairs. Two database files are shown in Figures 15.1 and 15.2 on pages 382–383 and 391. The first shows a number of typical, real-world entries, while the second has been designed to demonstrate special points in the examples. In this section we study the allowed syntax of database entries in some detail; see also [162].

When using the 7-bit application BibTeX, the file should normally be a pure ASCII file; BibTeX8 as described in Section 15.2.1 can handle also 8-bit code pages. In contrast, biber supports all file encodings — using it with the now de facto standard UTF-8 is highly recommended.

The different requirements regarding the file encoding show that the format of the BibTeX database is quite flexible. This made it possible to adapt and extend the format over time to support modern needs like new fields to store a Uniform Resource Locator (URL) and references to digital archives, but it also means that it can depend on the post-processor, on the BibTeX style, and even on document settings if a field is used and which values it expects. Most notably there are a number of differences between a database meant for a BibTeX workflow and a database meant for biblatex and biber that stem from the much more powerful abilities of the latter to handle, e.g., dates, cross references, annotated data, new fields, and Unicode. Such differences are shown in small boxes, which will also often contain tips on how to stay compatible with a BibTeX workflow in such cases.

biber/biblatex

The text in boxes such as this explain features specific to the biber/biblatex workflow and may give advice on what to do (or what not to use) when compatibility with the BibTeX workflow is required.

Each entry in a BibTeX database consists of three main parts: a *type* specifier, followed by a *key*, and finally the *data* for the entry itself. The *type* describes the general nature of the entry (e.g., whether it is an article, book, or some other publication). The *key* is used in the interface to L^AT_EX; it is the string that you have to place in the argument of a `\cite` command when referencing that particular entry. The *data* part consists of a series of *field entries* (depending on the *type*), which can have one of two forms as seen in the following generic format and example:

```
@type_specifier{key_identifier,      @book{lamport86,
  field_name_1 = "field_text_1",      author = "Leslie Lamport",
  field_name_2 = {field_text_2},      title  = "{\LaTeX{}} A Document
  . . .                               Preparation system",
  field_name_n = {field_text_n}      publisher = {Addison-Wesley},
}                                     year    = 1986
}
```

The comma is the field separator. Spaces surrounding the equal sign or the comma are ignored. Inside the text part of a field (enclosed in a pair of double quotes or a pair of braces) you can have any string of characters, but braces must be matched. The quotes or braces can be omitted for text consisting entirely of numbers (like the year field in the example above).

Note that L^AT_EX's comment character `%` is not a comment character inside `.bib` database files and even leads to parsing errors if used inside of an entry. Instead, anything outside an entry is considered a comment as long as it does not contain an `@` sign (which would be misinterpreted as the start of a new entry). Thus, to comment a field in an entry, change the name of the field to an ignored name or place it outside the entry. To exclude a full entry, remove the starting `@` sign.

Comments in the
.bib file

```

biber/biblatex

biber recognizes L^AT_EX's comment character %, and it is possible to exclude entries with it. Like B_BT_EX it ignores text in the .bib file, which does not belong to an entry, but it reports such text as junk characters in the .blg file (the log file of B_BT_EX and biber) unless the lines start like in a T_EX file with a percent char.

The `key_identifier` can be freely chosen but should use only ASCII characters and should not contain a space or any one of the characters " # % , = { } ~ \.

B_BT_EX *ignores* the case of the letters for the entry type, key, and field names. You must, however, be careful with the key. L^AT_EX honors the case of the keys specified as the argument of a \cite command, so the key for a given bibliographic entry must match the one specified in the L^AT_EX file (see Section 16.2.1).

biber/biblatex

With biber the key of the entry should not contain a space or any one of the characters " # % , = { } ' () ~ \. Most important, that means that a key `author(1998)`, which is allowed with B_BT_EX, is not recognized correctly with biber. Keys can contain non-ASCII chars, so `Sträßer.2010` is allowed, but it should be used only if compatibility with B_BT_EX is not needed and if the .tex and .bib files use matching file encodings — at best UTF-8.

Various schemes exist for conveniently associating bibliography keywords with their entries in a database. A popular one is the so-called Harvard system, where you take the author's surname (converted to lowercase) and the year of publication and combine them using a colon (e.g., `smith:1987`).

15.3.1 Entry types and fields

As discussed above, you must describe each bibliographic entry as belonging to a certain type, with the information itself tagged by certain fields.

The first thing you have to decide is what type of entry you are dealing with. Although no fixed classification scheme can be complete, with a little creativity you can make B_BT_EX cope reasonably well with even the more bizarre types of publications. For nonstandard types, it is probably wise not to attach too much importance to B_BT_EX's or biber's warning messages (see below).

Most B_BT_EX styles have at least the 13 standard entry types, which are shown in Table 15.1 on page 386.

These different types of publications demand different kinds of information; a reference to a journal article might include the volume and number of the journal, which is usually not meaningful for a book. Therefore, different database types have different fields. In fact, for each type of entry, the fields are divided into three classes:

Required Omission of the field produces a warning message and, possibly, a badly formatted bibliography entry. If the required information is not meaningful, you

are most likely using the wrong entry type. If it is meaningful but, say, already included in some other field, ignore the warning, but check that the typeset entry is not mangled.

Optional The field's information is used if present, but you can omit it without causing formatting problems. Include the optional field if it can help the reader.

Ignored The field is ignored. BibTeX ignores any field that is not required or optional, so you can include any fields in a .bib file entry. It is a good idea to put all relevant information about a reference in its .bib file entry, even information that may never appear in the bibliography. For example, the abstract of a paper can be entered into an abstract field in its .bib file entry. The .bib file is probably as good a place as any for the abstract, and there exist bibliography styles for printing selected abstracts (see the abstract bibliography style mentioned in Table 15.7 on page 420).

biber/biblatex

With biber the abstract field is not ignored. This can lead to errors in the L^AT_EX compilation if this field has been used in the past to record data that were not expected to be typeset, e.g., contains hashes, #, or a percent characters, %.

Either such special characters should be correctly escaped or the processing of the field should be suppressed with a source map as described in Example 15-3-5 on page 408.

Table 15.1 on the following page describes the standard entry types, along with their required and optional fields, as used by the standard bibliography styles. The fields within each class (required or optional) are listed in the typical order of occurrence in the output. A few entry types, however, may perturb the alphabetic ordering slightly, depending on which fields are missing. The meaning of the individual fields is explained in Tables 15.3/4 on pages 388–389. Nonstandard bibliography styles may ignore some optional fields or use additional ones like isbn when creating the reference (see also the examples starting on page 419). Remember that, when used in a .bib file, the entry-type name is preceded by an @ character.

biber/biblatex

Table 15.2 on page 387 shows which additional standard entry types are supported by biblatex along with their required fields. The list of optional fields supported by each type is not shown because it is much longer than in a typical BibTeX style: all entry types for example support fields for various electronic identifiers, fields to change sorting, date fields, and generic fields. So only some important new fields are described below, but for the full list the biblatex documentation should be consulted. The file blx-dm.def, which is part of the biblatex package, contains the declaration of the default entry types, the fields they support, and the constraints on these fields and so can be consulted for details.

article	An article from a journal or magazine. <i>Required:</i> author, title, journal, year. <i>Optional:</i> volume, number, pages, month, note.
book	A book with an explicit publisher. <i>Required:</i> author or editor, title, publisher, year. <i>Optional:</i> volume or number, series, address, edition, month, note.
booklet	A work that is printed and bound, but without a named publisher or sponsoring institution. <i>Required:</i> title. <i>Optional:</i> author, howpublished, address, month, year, note.
inbook	A part of a book, e.g., a chapter, section, or whatever and/or a range of pages. [biber/biblatex difference: Use the type only for a self-contained part with its own title.] <i>Required:</i> author or editor, title, chapter and/or pages, publisher, year. <i>Optional:</i> volume or number, series, type, address, edition, month, note.
incollection	A part of a book having its own title. <i>Required:</i> author, title, booktitle, publisher, year. <i>Optional:</i> editor, volume or number, series, type, chapter, pages, address, edition, month, note.
inproceedings	An article in a conference proceedings. <i>Required:</i> author, title, booktitle, year. <i>Optional:</i> editor, volume or number, series, pages, address, month, organization, publisher, note.
manual	Technical documentation. <i>Required:</i> title. <i>Optional:</i> author, organization, address, edition, month, year, note.
mastersthesis	A master's thesis. [biber/biblatex difference: The type is provided as an alias of the new type thesis.] <i>Required:</i> author, title, school, year. <i>Optional:</i> type, address, month, note.
misc	Use this type when nothing else fits. A warning is issued if all optional fields are empty (i.e., the entire entry is empty or has only ignored fields). <i>Required:</i> none. <i>Optional:</i> author, title, howpublished, month, year, note.
phdthesis	A Ph.D. thesis. [biber/biblatex difference: The type is provided as an alias of the new type thesis.] <i>Required:</i> author, title, school, year. <i>Optional:</i> type, address, month, note.
proceedings	Conference proceedings. <i>Required:</i> title, year. <i>Optional:</i> editor, volume or number, series, address, publisher, note, month, organization.
techreport	A report published by a school or other institution, usually numbered within a series. [biber/biblatex difference: The type is provided as an alias of the new type report.] <i>Required:</i> author, title, institution, year. <i>Optional:</i> type, number, address, month, note.
unpublished	A document having an author and title, but not formally published. <i>Required:</i> author, title, note. <i>Optional:</i> month, year.

Table 15.1: BiBTeX's entry types as defined in most styles

<code>bookinbook</code>	This type is similar to <code>inbook</code> but intended for works originally published as a stand-alone book. A typical example is a book reprinted in the collected works of an author.
<code>collection</code>	A single-volume collection with multiple, self-contained contributions by distinct authors that have their own title. <i>Required:</i> <code>editor</code> , <code>title</code> , <code>year/date</code> .
<code>dataset</code>	A data set or a similar collection of (mostly) raw data. <i>Required:</i> <code>author/editor</code> , <code>title</code> , <code>year/date</code> .
<code>mvbook</code> <code>mvcollection</code> <code>mvproceedings</code> <code>mvreference</code>	Multivolume variants of the entry types.
<code>online</code>	This entry type is intended for sources such as websites, which are intrinsically online resources. <i>Required:</i> <code>doi/eprint/url</code> , <code>year/date/urldate</code> .
<code>patent</code>	A patent or patent request. <i>Required:</i> <code>author</code> , <code>title</code> , <code>number</code> , <code>year/date</code> .
<code>periodical</code>	A complete issue of a periodical, such as a special issue of a journal. <i>Required:</i> <code>editor</code> , <code>title</code> , <code>year/date</code> .
<code>reference</code>	A single-volume work of reference such as an encyclopedia or a dictionary, handled quite similar to <code>collection</code> .
<code>report</code>	A technical report, research report, or white paper published by a university. <i>Required:</i> <code>author</code> , <code>title</code> , <code>type</code> , <code>institution</code> , <code>year/date</code> .
<code>set</code>	An “entry set”. This is a group of entries that are cited as a single reference and listed as a single item in the bibliography.
<code>software</code>	Computer software. The standard styles treat this entry type as an alias for <code>@misc</code> .
<code>suppbook</code> <code>suppcollection</code> <code>suppperiodical</code>	Supplemental material like a preface.
<code>thesis</code>	A thesis written for an educational institution to satisfy the requirements for a degree. <i>Required:</i> <code>author</code> , <code>title</code> , <code>type</code> , <code>institution</code> , <code>year/date</code> .
<code>xdata</code>	This entry type is special. <code>xdata</code> entries hold data that may be inherited by other entries using the <code>xdata</code> field.

Table 15.2: Additional standard entry types provided by biblatex

Most BibTeX style files sort the bibliographical entries. This is done by internally generating a sort key from the author’s/editor’s name, the date of the publication, the title, and other information. Entries with identical sort keys appear in citation order.

*Sorting of
entries*

The author information is usually the `author` field, but some styles use the `editor` or `organization` field. In addition to the fields listed in Table 15.1, each entry type has an optional `key` field, used in some styles for alphabetizing, for cross-referencing, or for forming a `\bibitem` label. You should therefore include a key

address	Usually the address of the publisher or other institution. For major publishing houses, just give the city. For small publishers, specifying the complete address might help the reader. [biber/biblatex difference: location should be used instead, but address is provided as an alias.]
annote	An annotation. Not used by the standard bibliography styles, but used by others that produce an annotated bibliography (e.g., <code>annote</code>). The field starts a new sentence, and hence the first word should be capitalized. [biber/biblatex difference: annotation should be used instead, but annote is provided as an alias.]
author	The name(s) of the author(s), in BibTeX name format (Section 15.3.3).
booktitle	Title of a book, part of which is being cited (Section 15.3.3). For book entries use the <code>title</code> field.
chapter	A chapter (or section or whatever) number.
crossref	The database key of the entry being cross-referenced (Section 15.3.7).
edition	The edition of a book (e.g., “Second”). This should be an ordinal and should have the first letter capitalized, as shown above; the standard styles convert to lowercase when necessary. [biber/biblatex difference: This must be a number, not an ordinal.]
editor	Name(s) of editor(s), in BibTeX name format. If there is also an <code>author</code> field, then the <code>editor</code> field gives the editor of the book or collection in which the reference appears.
howpublished	How something strange has been published.
institution	Institution sponsoring a technical report.
journal	Journal name. Abbreviations are provided for many journals (Section 15.3.4). [biber/biblatex difference: journaltitle should be used instead, but journal is provided as an alias.]
key	Used for alphabetizing and creating a label when the <code>author</code> and <code>editor</code> information is missing. This field should not be confused with the key that appears in the <code>\cite</code> command and at the beginning of the database entry. [biber/biblatex difference: sortkey should be used instead, but key is provided as an alias. biblatex offers additional fields like sortname and sorttitle for finer control.]

Table 15.3: BibTeX’s standard entry fields (A–K)

field for any entry whose author information is missing. Depending on the style, the `key` field can also be used to overwrite the automatically generated internal key for sorting.¹ A situation where a `key` field is useful is the following:

```
organization = "The Association for Computing Machinery",
key = "ACM"
```

Without the `key` field, the `alpha` style would construct a label from the first three letters of the information in the `organization` field. Although the style file strips off the article “The”, you would still get a rather uninformative label like “[Ass86]”.

¹ Some BibTeX styles (e.g., `jurabib`) use the `sortkey` field instead.

month	The month in which the work was published or, for an unpublished work, in which it was written. For reasons of consistency the standard three-letter abbreviations (<code>jan</code> , <code>feb</code> , <code>mar</code> , etc.) should be used (Section 15.3.4). [biber/biblatex difference: This must be a number. It is also recommended to use the <code>date</code> field instead.]
note	Any additional information that can help the reader.
number	The number of a journal, magazine, technical report, or work in a series. An issue of a journal or magazine is usually identified by its volume and number; a technical report normally has a number; and sometimes books in a named series carry numbers.
organization	The organization that sponsors a conference or that publishes a manual.
pages	One or more page numbers or range of numbers (e.g., 42--111 or 7,41,73--97 or 43+, where the '+' indicates pages that do not form a simple range). [biber/biblatex difference: The 42+ syntax is not known.]
publisher	The publisher's name.
school	The name of the school where the thesis was written.
series	The name of a series or set of books. When citing an entire book, the <code>title</code> field gives its title, and an optional <code>series</code> field gives the name of a series or multivolume set in which the book is published.
title	The work's title, typed as explained in Section 15.3.3.
type	The type of a technical report (e.g., "Research Note"). This name is used instead of the default "Technical Report". For the entry type <code>phdthesis</code> you could use the term "Ph.D. dissertation" by specifying <code>type = "{Ph.D.} dissertation"</code> . Similarly, for the <code>inbook</code> and <code>incollection</code> entry types you can get "section 1.2" instead of the default "chapter 1.2" with <code>chapter = "1.2"</code> and <code>type = "Section"</code> .
volume	The volume of a journal or multivolume book.
year	The year of publication or, for an unpublished work, the year it was written. Generally, it should consist of four numerals, such as 1984, although the standard styles can handle any year whose last four nonpunctuation characters are numerals, such as "about 1984". [biber/biblatex difference: This must be a number; using the <code>date</code> field instead is recommended.]

Table 15.4: BibTeX's standard entry fields (L–Z)

Using the `key` field yields a more acceptable "[ACM86]".

biber/biblatex

The "main" sort key is called `sortkey`, and the alias key is available too. It is complemented by the fields `sortname`, `sortyear`, `sorttitle`, and `sortshorthand`, which give finer control over the sorting process.

Different from BibTeX, `sortkey` and its alias key are never used as a fallback to create a label. Depending on the use case, one of the fields `shortauthor`, `shorteditor`, or `label` should be used for this purpose.

We now turn our attention to the fields recognized by the standard bibliography styles. These "standard" fields are shown in Tables 15.3/4 on pages 388–389. Other

fields, like `abstract`, can be required if you use one of the extended nonstandard styles shown in Tables 15.7–10 on pages 420–424. Because unknown fields are ignored by the \LaTeX styles, you can use this feature to include “comments” inside an entry: it is enough to put the information to be ignored inside braces following a field name (and `=` sign) that is not recognized by the \LaTeX style.

As with the names of the entry types in Table 15.1 on page 386, the names of the fields should be interpreted in their widest sense to make them applicable in a maximum number of situations. And you should never forget that a judicious use of the `note` field can solve even the more complicated cases.

15.3.2 Additional fields

A number of fields are not supported by the standard \LaTeX styles but are of such general use that it is typically recommended to add them to the `.bib` file and if possible to use a \LaTeX style that knows these fields.

*URL and other
electronic identifiers*

\LaTeX and its standard styles were developed when the Internet was in its infancy and so do not support fields for URL, DOI, eprint, and similar data. When using these styles, such data have to be entered in the `note` or `howpublished` field. While this was a workable solution fifteen years ago when one could still write that references to electronic resources have become “more and more common”, it is in today’s world often not compatible with modern journal styles that expect that dedicated fields are used. It is therefore normally preferable to use the `url`, `doi`, and `eprint` fields for such data. Variants of the standard styles supporting these fields are for example provided by the package `urlbst` from Norman Gray or by `babelbib` from Harald Harders. Styles with an `url` field can also be created with `custom-bib`.

If the URL should be used for a clickable link, it should be correctly percent encoded. References pointing to an online resource typically should also contain the date when this resource was accessed. The predominant field names for this are `urldate` and `lastchecked`.

biber/biblatex

`biber` and `biblatex` provide a full set of fields in this area: `doi`, `eid`, `eprint`, `eprintclass`, `eprinttype`, `isan`, `isbn`, `ismn`, `isrn`, `issn`, `iswc`, `url`, and `urldate`.

The `eprint`, `eprintclass`, and `eprinttype` fields, for example, can be used to replace longish URLs in a bibliography for a large number of known resources like `arXiv`, `jstor`, or `pubmed`:

```
eprint      = {cs/0011047v1},
eprintclass = {cs.DS},
eprinttype  = {arxiv}
```

This typesets “arXiv: cs/0011047v1 [cs.DS]”, and — if `hyperref` is loaded — hyperlinks it to <https://arxiv.org/abs/cs/0011047v1>.

It is possible to store URLs with non-ASCII characters and spaces. `biber` converts such URLs into the percent-encoded representation needed for a

Figure 15.2: A second sample BibTeX database (tlc-ex.bib)

This database contains various short, fictitious entries to produce concise examples.

correct link. If the URL is already percent encoded, it is left unchanged, so normally there should be no conflict with input meant for BibTeX.

biber requires that the date in `urldate` is in ISO 8601-2 format. If this is not possible, the ISO-date can be put in another field, and when using biblatex, a source map can be used to map this field to `urldate`:

```
\DeclareSourcecmap{
  \maps{\map[overwrite]{\step[fieldsource=urllisodate,
                                fieldtarget=urldate,final]}}
```

More details about entering dates in such fields are given on page 400.

Language support

A second type of field is related to the language of an entry. The styles from the `babelbib` package, for example, offer here the field `language`. If set to a name known by `babel`, it adapts generated text of an entry to that language. The following example shows the output of two entries of `tlc-ex.bib` from Figure 15.2 that differ only in the `language` setting: the first uses `french` and the second `english`.

\usepackage{hyperref}

\bibliographystyle{babplain}
\nocite{url:a,url:b}
\bibliography{tlc-ex}
```

15-3-1

biber/biblatex

biblatex declares the fields `langid` and `language`:

langid This field declares the language rules to use when typesetting the entry in the bibliography. Depending on the setting of the package option `autolang` (which takes the values `none`, `hyphen`, `other`, and `other*`), it does nothing, changes only the hyphenation, or switches to the language by using the corresponding `babel` environments. It has a comparable purpose to the `language` field of `babelbib`, and a source map should be used to map `language` to `langid` if needed.

language This field takes a list of languages separated by the `and` delimiter describing the languages of the work. The languages can be given literally or as a “localization key” — strings that represent a term, which can be translated with the localization commands of `biblatex`.

Example 15-3-2 shows for three entries how `biblatex` handles the `language` and `langid` settings. It uses again entries that differ only in these fields:

```
language = {french and spanish},          langid = {french} %url:c
```

```
language = {spanish with some translations},langid ={spanish} %url:d
language = {english}, langid ={english} %url:e
```

Note in the example how the value `other` for the `autolang` option triggered the translation of various words in the Spanish and French entries and that the French entry uses French typographical rules like the space before the colon. The text “spanish with some translations” in the second entry is not translated and not capitalized as it is not a known localization key. Note also that the English entry does not show the language because it is identical to the main language of the document.

15-3-2

15.3.3 The text part of a field explained

The text part of a field in a BibTeX entry is enclosed in a pair of double quotes or braces. Part of the text itself is said to be *enclosed in braces* if it lies inside a matching pair of braces other than the ones enclosing the entire entry.

The field types have quite varied requirements regarding the parsing of the text, but for BibTeX no formal description of the data types exists. Most rules are given only implicitly through the existing BibTeX styles and the functions they implement.

biber/biblatex

With biber this is different: all fields have a declared and documented data type. There are three main data types:

Name lists are split up into individual items at the “and” delimiter. Each item in the list is then dissected into the name part components. Examples of name list fields are the author or the editor field. Most rules for the formatting and the parsing of names have been inherited from BibTeX. More details are given below.

Literal lists are also split up at the “and” delimiter but unlike names not dissected further. Examples are the location, the publisher, and the language field. The splitting of these texts into list elements allows localization of parts as has been shown above for languages, but it allows also localization and formatting of conjunctions: New York and London can be converted to “New York & London” or “New York et London” or ...

Fields are usually printed as a whole. There are several subtypes like integers, dates, or URLs.

The structure of a name

The `author` and `editor` fields contain a list of names. The exact format in which these names are typeset is decided by the bibliography style. The entry in the database tells BibTeX what the name is. You should always type names exactly as they appear in the cited work, even when they have slightly different forms in two works. For example:

```
author = "Donald E. Knuth"           author = "D. E. Knuth"
```

If you are sure that both authors are the same person, then you could list both in the form that the author prefers (say, Donald E. Knuth), but you should always indicate (e.g., in our second case) that the original publication had a different form.

```
author = "D[onald] E. Knuth"
```

BibTeX alphabetizes this as if the brackets were not there so that no ambiguity arises as to the identity of the author.

biber/biblatex

biber does not automatically ignore brackets, but it can be instructed to do so (and other character in names) either in a configuration file in XML notation

```
<nonamestring>
  <option name="author" value="[]" />
</nonamestring>
```

or in the document with the `\DeclareNonamestring` command:

```
\DeclareNonamestring{%
  % strip square brackets
  \nonamestring{author}{\regex{[[]\[]}}}
```

The interface supports Perl regular expressions¹ in various places; for details see the biber documentation.

Most names can be entered in the following two equivalent forms:

```
"John Chris Smith"           "Smith, John Chris"
"Thomas von Neumann"         "von Neumann, Thomas"
```

The second form, with a comma, should always be used for people who have multiple last names that are capitalized. For example,

```
"Parra Benavides, Miguel"
```

If you enter "Miguel Parra Benavides", BibTeX interprets Parra as the middle name, which is wrong in this case. When the other parts are not capitalized, no such problem occurs (e.g., "Johann von Bergen" or "Pierre de la Porte").

¹See, for example, <https://perldoc.perl.org/perlre>.

If several words of a name have to be grouped, they should be enclosed in braces. BibTeX treats everything inside braces as a single name, as shown below:

```
"{Boss and Friends, Inc.} and {Snoozy and Boys, Ltd.}"
```

In this case, Inc. and Ltd. are not mistakenly considered as first names.

In general, BibTeX names can have four distinct parts, denoted as *First*, *von*, *Last*, and *Jr.* Each part consists of a list of name tokens, and any list but *Last* can be empty. Thus, the two entries below are different:

```
"von der Schmidt, Alex"           "{von der Schmidt}, Alex"
```

The first has *von*, *Last*, and *First* parts, while the second has only *First* and *Last* parts (von der Schmidt), resulting possibly in a different sorting order.

A “Junior” part can pose a special problem. Most people with “Jr.” in their name precede it with a comma, thus entering it as follows:

```
"Smith, Jr., Robert"
```

Certain people do not use the comma, and these cases are handled by considering the “Jr.” as part of the last name:

```
"{Lincoln Jr.}, John P."           "John P. {Lincoln Jr.}"
```

Recall that in the case of “Miguel Parra Benavides”, you should specify

```
"Parra Benavides, Miguel"
```

The *First* part of his name has the single token “Miguel”; the *Last* part has two tokens, “Parra” and “Benavides”; and the *von* and *Jr* parts are empty.

A complex example is

```
"Johannes Martinus Albertus van de Groene Heide"
```

This name has three tokens in the *First* part, two in the *von* part, and two in the *Last* part. BibTeX knows where one part ends and the other begins because the tokens in the *von* part begin with lowercase letters (van de in this example).

In general, *von* tokens have the first letter at brace-level 0 in lowercase. Technically speaking, everything in a “special character” is at brace-level 0 (see page 398), so you can decide how BibTeX treats a token by inserting a dummy special character whose first letter past the TeX control sequence is in the desired case, upper or lower. For example, in

```
Maria {\MakeUppercase{d}e La} Cruz
```

BibTeX takes the uppercase “De La” as the *von* part, because the first character following the control sequence is lowercase. With the *abbrv* style you get the correct abbreviation M. De La Cruz, instead of the incorrect M. D. L. Cruz if you did not use this trick.

BB_TE_X handles hyphenated names correctly. For example, an entry like

```
author = "Maria-Victoria Delgrande",
```

with the `abbrv` style results in “M.-V. Delgrande”.

When multiple authors are present, their names should be separated with the word “and”, where the “and” must not be enclosed in braces.

```
author = "Frank Mittelbach and Rowley, Chris"
editor = "{Lion and Noble, Ltd.}"
```

There are two authors, Frank Mittelbach and Chris Rowley, but only one editor, because the “and” is enclosed in braces. If the number of authors or editors is too large to be typed *in extenso*, then the list of names can be ended with the string “and_others”, which is converted by the standard styles into the familiar “*et al.*”

To summarize, you can specify names in BB_TE_X using three possible forms (the double quotes and braces can be used in all cases):

"First von Last"	e.g., {Johan van der Winden}
"von Last, First"	e.g., "von der Schmidt, Alexander"
"von Last, Jr, First"	e.g., {de la Porte, Fils, {\`Emile}}

The first form can almost always be used. It is, however, not suitable when there is a *Jr* part or when the *Last* part has multiple tokens and there is no *von* part.

biber/biblatex

The name parts *First*, *von*, *Last*, and *Jr* are called *given*, *prefix*, *family*, and *suffix* both in templates and command names. Initials are indicated by attaching an *i*, e.g., *given-i* or `\namepartgiveni`.

`biber` can process names given in key/value syntax. In this syntax the name Maria De La Cruz can be entered without the `\MakeUpperCase` trick:

```
author={family=Cruz,given=Maria,prefix=De La}
```

It is possible to declare keys for additional name parts and special name templates and to print names using other rules than Western names. The file `93-nameparts.tex` in the example suite of `biblatex` contains the details; here we show only two name types that can be used with this system once it has been properly set up. The `cjk` template ensures that the name of the first author is typeset as Li Wei or Li, while the `ethiopian` template prints the second author as Kebede Daniel or — if needed to make the name unique — as Kebede Daniel Demeke.

```
author = {family=Li, given=Wei, nametemplates=cjk},
author = {given=Kebede, patronymic=Daniel, papponymic=Demeke,
          nametemplates=ethiopian},
```

Names not using the extended syntax are parsed by biber quite similarly to BibTeX. However, some tricks described in *Tame the Beast* [124] to get longer initials, to improve labels in alphabetic styles, and to handle special prefixes and name parts can be problematic. As an example, to get a initial consisting of two letters you can with BibTeX use

```
author={Loe,{\relax Ch}arles}
```

This does not work with biber — the extended syntax is required instead:

```
author={family=Loe,given=Charles,given-i={Ch}}
```

Other tricks do not harm but are unnecessary. As a rule of thumb, names with unusual initials or prefixes are input at best with the extended name syntax. Special labels for alphabetic styles can be set with the `label` field.

The next two examples use again some bibliography entries from the sample database in Figure 15.2 on page 391 to demonstrate different input options. The first shows the result when using the BibTeX workflow. As you can see, BibTeX is unable to handle any of the biber-specific input conventions correctly and produces strange labels (third list entry) or badly formatted output (entries five and six):

\nocite{prefix-biber,
  label-biber,apostroph-biber}
\bibliographystyle{alpha}
\footnotesize
\bibliography{tlc-ex}
```

In contrast biber and biblatex do a good job on all syntax variants as shown in the second example. Note that the BibTeX style `alpha` creates labels that use the *von* part, while biblatex ignores it by default, resulting in more readable labels:

15-3-3

15-3-4

The format of the title

The bibliography style decides whether a title is capitalized. Usually, titles of books are capitalized, but those for articles are not. A title should always be typed as it appears in the original work. For example:

```
TITLE = "A Manual of Style"
TITLE = "Hyphenation patterns for ancient Greek and Latin"
```

Different languages and styles have their own capitalization rules. If you want to override the decisions of the bibliography style, then you should enclose the parts that should remain unchanged inside braces. Note that this is not sufficient when the first character after the left brace is a backslash (see below). It is usually best to enclose whole words in braces, because otherwise \LaTeX may lose kerning or ligatures when typesetting the word. In the following example, the first version is preferable over the second:

```
TITLE = "The Towns and Villages of {Belgium}"
TITLE = "The Towns and Villages of {B}elgium"
```

biber/biblatex

Capitalization or “sentence casing” is not done by the biber preprocessor, but during the \LaTeX compilation, and will be discussed in more detail when we describe the biblatex package in Chapter 16.

As with \BibTeX , words can be excluded from sentence casing by enclosing them in braces. Arguments of commands are protected too. To *undo* this protection to enable sentence casing in arguments or parts thereof, you have to use another pair of braces, e.g.,

```
title={a Story of \emph{Green} and {\emph{Blue}} {Ducks}}
```

Here “Green” and “Ducks” are protected from sentence casing, while the protection for “Blue” has been undone. The output if sentence casing is applied will be “A story of *Green* and *blue* Ducks”.

Accented and special characters

\BibTeX accepts accented characters. If you have an entry with two fields

```
author = "Kurt G{\"o}del", year = 1931,
```

then the alpha bibliography style yields the label [Göd31], which is probably what you want. As shown in the example above, the entire accented character must be placed in braces; in this case either $\{"o\}$ or $\{"{o}\}$ will work. These braces must not themselves be enclosed in braces (other than the ones that might delimit the entire field or the entire entry); also, a backslash must be the very first character inside the braces. Thus, neither $\{G\{"{o}\}\del\}$ nor $\{G\{"{o}\}\del\}$ works here.

This feature handles accented characters and foreign symbols used with \LaTeX . It also allows user-defined “accents”. For the purposes of counting letters in labels, \BibTeX

considers everything inside the braces to be a single letter. To BibTeX, an accented character is a special case of a “special character”, which consists of everything from a left brace at the topmost level, immediately followed by a backslash, up through the matching right brace. For example, the field

```
author = "\OE{le} {\'}{E}mile} {Ren\'}{e}} van R{\i{j}den"
```

has two special characters: “{\'}{E}mile}” and “{\i{j}”.

In general, BibTeX does not process TeX or LaTeX control sequences inside a special character, but it processes other characters. Thus, a style that converts all titles to lowercase transforms

“The {\TeX BOOK\NOOP} Saga” into “The {\TeX book\NOOP} saga”

The article “The” remains capitalized because it is the first word in the title.

The special character scheme has its uses for handling accented characters, although the introduction of additional braces may upset the generation of ligatures and kerns, and — as has been mentioned at the begin of Section 15.2 — the capabilities of BibTeX to sort names with such accents are quite restricted. It may help to make BibTeX’s alphabetizing do what you want, but again with some caveats; see the discussion of the \SortNoop command on page 405. Also, because BibTeX counts an entire special character as just one letter, you can force extra characters inside labels.

biber/biblatex

biber can handle UTF-8 and 8-bit encoded .bib files. Accented chars can be input directly, but it is also possible to use accent commands. Unlike BibTeX, biber does not ignore these commands when sorting; instead, it tries to convert them into their respective Unicode code points. For most standard accent commands this works fine, but a small number of odd inputs can give errors. Well known is the problem with {\'}{i} (i) that is converted by biber into a dotless i (U+0131) followed by the combining accent U+0301. pdflatex cannot handle this combination and errors. The best advice here is to replace such commands with the correct UTF-8 input í or to use {\'}{i}.

The biber program can also convert a .bib file with accented characters back to a pure ASCII:

```
biber --tool --output-safechars <file>.bib
```

This creates *file_bibertool.bib* in which a line such as

```
author={Ele Émile René van Ríjden},
```

is replaced by

```
AUTHOR = {van R{\i{j}den, \OE{le} \'}{E}mile Ren\'}{e}},
```

The encoding of the input file can be set with the option `--input-encoding`. As the default, UTF-8 is assumed.

<i>Description</i>	<i>Date input</i>	<i>Exemplary output</i>

date with time	2004-04-05T14:34:00	05/04/2004 2:34 PM

^aThe extended date format follows ISO 8601-2. Seasons have the “month” numbers 21–24 in this norm.

Table 15.5: Examples of biblatex date inputs

Dates

All BibTeX styles support the `year` and `month` fields. Normally they should contain integers, but text like `year={n.D.}` is possible too. Months can also be given as three-letter abbreviations *without* quotes or braces as in `month=jan`; see Section 15.3.4. Newer BibTeX styles often also know the `urldate` field. Dates are normally not localized. You need to find a suitable style if, e.g., the month name should be output in another language.

biber/biblatex

The fields `year` and `month` can be used but should contain only integers. For compatibility with standard BibTeX, the three-letter strings for months are supported, but content like `year={n.D.}` or `month={January}` should be avoided; you do not get errors, but biber warns you that the sorting can be wrong.

biblatex provides four dedicated date fields: `date` for the publication date (it should be preferred over `year` and `month`), `urldate` for the access date of an URL, `eventdate` for the date of a conference or some other event in

a proceedings entry, and `origdate` for the publication date of the original edition of a reprinted work. All dates are fully localized and can be output in various formats. The fields can be used for sorting and comparison, and it is possible to access parts of a date like the month or the year. The date fields support ranges, time, BC dates, seasons, circa, and uncertain dates. To enable these features a date must be input in ISO 8601-2 format.

Table 15.5 shows some example input and possible formatting of the dates. These extended dates are not supported by BibTeX, so using them makes the `.bib` file incompatible with the BibTeX workflow, but to stay compatible with both workflows one can provide all three fields of the publication entry:

```
year  = 2020,
month = apr,
date  = {2020-04-01}
```

`biber` and `biblatex` then overwrite (with a warning) the `year` and `month` fields with values taken from the `date` field, while with BibTeX `date` is ignored.

15.3.4 Abbreviations in BibTeX

You can declare shorthands for BibTeX text field input for repeated use. Such an abbreviation is labeled with a string of ASCII characters starting with a letter and not containing a space or any of the following ten characters:

" # % ' () , = { }

Define your own abbreviations with the `@string` command in a `.bib` file, as shown below:

```
@string{AW          = "Addison--Wesley Publishing Company"}
@STRING{cacm        = "Communications of the ACM"}
@String{pub-AW      = {{Ad\-di\-son-Wes\-ley}}}
@String{pub-AW:adr  = "Reading, MA, USA"}
@String{TUG         = "\TeX{} Users Group"}
@String{TUG:adr     = {Providence, RI, USA}}
```

Abbreviations can be used in the text part of BibTeX fields, but they should not be enclosed in braces or quotation marks. With the above string definitions, the following two ways of specifying the `journal` field are equivalent:

```
journal = "Communications of the ACM"
journal = cacm
```

The case of the name for an abbreviation is not important, so `CACM` and `cacm` are considered identical, but BibTeX produces a warning if you mix different cases. Also, the `@string` command itself can be spelled as all lowercase, all uppercase, or a mixture of the two cases.

`@string` commands can appear anywhere in the `.bib` file, but an abbreviation must be defined before it is used. It is good practice to group all `@string` commands at the beginning of a `.bib` file or to place them in a dedicated `.bib` file containing only a list of abbreviations. The `@string` commands defined in the `.bib` file take precedence over any definition made in the style file. If an abbreviation is defined more than once, the most recent definition before the entry is used.

You can concatenate several strings (or `@string` definitions) using the concatenation operator, `#`. Given the definition

```
@STRING{TUB = {TUGboat }}
```

you can easily construct nearly identical `journal` fields for different entries:

```
@article{tub-98,   journal = TUB # 1998,   ...
@article{tub-99,   journal = TUB # 1999,   ...
@article{tub-00,   journal = TUB # 2000,   ...
```

Most bibliography styles contain a series of predefined abbreviations. As a convention, there should always be three-letter abbreviations for the months: `jan`, `feb`, `mar`, and so forth. In your `LaTeX` database files you should always use these three-letter abbreviations for the months, rather than spelling them explicitly. This assures consistency inside your bibliography.

Information about the day of the month is usually best included in the `month` field if you are using `LaTeX`. You might, for example, make use of the possibility of concatenation:

```
month = apr # "~1",
```

biber/biblatex

However, note that the `month` field should contain only the month if you are planning to use the database with `biber` and `biblatex`. A day should be included through the `date` field in that case.

Names of popular journals in a given application field are also made available as abbreviations in most styles. To identify them you should consult the documentation associated with the bibliographic style in question. The set of journals listed in Table 15.6 on the next page should be available in all `LaTeX` styles.

biber/biblatex

The journal abbreviations are not predefined in `biblatex` styles. Suitable `@string` or `xdata` entries must therefore be added explicitly.

You can easily define your own set of journal abbreviations by putting them in `@string` commands in their own database file and listing this database file as an argument to `LaTeX`'s `\bibliography` command or to `biblatex`'s `\addbibresource`.

Table 15.6: Predefined journal strings in BibTeX styles

15.3.5 Extended data references with biber: the xdata entry type

biber/biblatex

biber supports the `@string` command but offers also a more general solution to reuse data: the `xdata` entry type serves as a data container holding one or more fields. Data in `xdata` entries may be referenced and used by other entries. An `xdata` entry looks like other entries in the `.bib` file and can contain all known fields. The key of the `xdata` can be freely chosen but should not contain an equal symbol or a hyphen.

```
@xdata{hup,
  publisher = {Harvard University Press},
  location = {Cambridge, Mass.}}

@xdata{macmillan:name,
  publisher = {Macmillan}}

@xdata{macmillan:place,
  location = {New York and London}}

@xdata{somenames,
  author = {Maria Fisher and Julia Green},
  editor = {John Smith and Brian Brown}}
```

An `xdata` container can also reference other `xdata` entries through the `xdata`

field, which accepts a comma-separated list of xdata keys:

```
@xdata{macmillan,
  xdata = {macmillan:name,macmillan:place}}
```

The data can then be used as a whole with the xdata field:

```
@book{somebook:a,
  author = {Jane Doe},
  xdata  = {macmillan}}
```

This adds the publisher “Macmillan” and the location “New York and London” to the entry. As you can see, it is important to use a good naming structure for your xdata key names, because otherwise your database will be difficult to manage.

It is also possible to reference only individual fields and even parts of fields from an xdata entry.

```
@book{somebook:b,
  author      = {xdata=somenames-editor-1 and Maria Webb},
  editor      = {xdata=somenames-author-2},
  publisher    = {xdata=hup-publisher},
  location     = {xdata=macmillan:place-location}}
```

This gives an entry that is equivalent to the following:

```
@book{somebook:b,
  author      = {Smith, John and Webb, Maria},
  editor      = {Green, Julia},
  publisher    = {Harvard University Press},
  location     = {New York and London}}
```

There are a few important points to note here:

- The syntax of a reference to a part of an xdata field has the special form `xdata=key-field-index`, e.g., `xdata=somenames-editor-1`. The equal sign should not lead you to mistake this as a key/value input or a field setting: the reference is a special value, and there should be no spaces around the equal sign. The *index* is optional and allows you to select only one element from a list. If no index is given, the full list is returned.
- A field can pull only data from an xdata field of the same type. A field with names like `author` can retrieve data from another name field, e.g., the `editor` field, but not from a literal list like `location` or a simple field like `title`; see Section 15.3.3 for a description of the data types. biber issues a warning if the type of the reference is wrong.

BibTeX does not know the `xdata` entry type. If a `.bib` file using `xdata` should be used with BibTeX, all such references must be resolved. This can be done with `biber` in tool mode and the option `--output-resolve`, i.e.,

```
biber --tool --output-resolve <file>.bib
```

which creates the file `file_bibertool.bib` and converts entries with `xdata` fields or values, such as

```
@book{somebook:a,
  author = {Jane Doe and xdata=smithbrown-author-2},
  xdata  = {macmillan}
}
```

to the form

```
@BOOK{somebook:a,
  AUTHOR = {Doe, Jane and Brown, Brian},
  LOCATION = {New York and London},
  PUBLISHER = {Macmillan},
}
```

15.3.6 The BibTeX database preamble command

Both BibTeX and `biber` offer a `@preamble` command with a syntax similar to that of the `@string` command except that there is no name or equals sign, just the string. For example:

```
@preamble{ "\providecommand\url[1]{\texttt{#1}}" #
           "\providecommand\SortNoop[1]{}"      }
@preamble{ "\providecommand\enquote[1]{‘#1’}" }
```

You can see that the different command definitions inside the `@preamble` can be given as separate strings that are then concatenated using the `#` symbol. It is also possible to use `@preamble` more than once. Both are useful for readability if you have many definitions. The standard styles output the argument of the `@preamble` literally to the `.bbl` file so that the command definitions are available when L^AT_EX reads the file. If you add L^AT_EX commands in this way, you must ensure that they are added using `\providecommand` and not `\newcommand`. There are two reasons for this requirement. First, you should not deprive yourself of the ability to change the definition in the document (e.g., the bibliography might add a simple definition for the command `\url` that you may want to replace by the definition from the `url` package). Second, sometimes the bibliography is read in several times (e.g., with the `chapterbib` package), an operation that would fail if `\newcommand` were used.

The other example command used above (`\SortNoop`) was suggested by Oren Patashnik to guide BibTeX's sorting algorithm in difficult cases. This algorithm normally does an acceptable job, but sometimes you might want to override BibTeX's decision by specifying your own sorting key. This trick can be used with foreign languages, which have sorting rules different from those of English, or when you want to order the various volumes of a book in a way given by their original date of publication and independently of their re-edition dates.

Suppose that the first volume of a book was originally published in 1986, with a second edition appearing in 1991, and the second volume was published in 1990. Then you could write

```
@book{ ... volume=1, year = "{\SortNoop{86}}1991" ...
@book{ ... volume=2, year = "{\SortNoop{90}}1990" ...
```

According to the definition of `\SortNoop`, L^AT_EX throws away its argument and ends up printing only the true year for these fields. For BibTeX `\SortNoop` appears to be an “accent”; thus, it sorts the works according to the numbers 861991 and 901990, placing volume 1 before volume 2, just as you want.

Be aware that the above trick may not function with newer BibTeX styles (for example, those generated with `custom-bib`) and that some styles have added a `sortkey` field that solves such problems in a far cleaner fashion.

biber/biblatex

Tricks like the `\SortNoop` command are normally not needed because there are enough sort keys to handle a variety of use cases.

15.3.7 Cross-referencing entries

BibTeX entries can be cross-referenced. Suppose you specify `\cite{Wood:color}` in your document, and you have the following two entries in the database file:

```
@Inbook{Wood:color, author = {Pat Wood}, crossref={Roth:postscript},
title = {PostScript Color Separation}, pages={201--225}}
@Book{Roth:postscript, editor = {Stephen E. Roth}, title =
{{Real World PostScript}}, booktitle = {{Real World PostScript}},
publisher=AW, address=AW:adr, year=1988, ISBN={0-201-06663-7}}
```

The special `crossref` field tells BibTeX that the `Wood:color` entry should inherit missing fields from the entry it cross-references — `Roth:postscript`. BibTeX automatically puts the `Roth:postscript` entry into the reference list if it is cross-referenced by a certain number of entries (default 2) on a `\cite` or `\nocite` command, even if the `Roth:postscript` entry itself is never the argument of a `\cite` or `\nocite` command. Thus, with the default settings, `Roth:postscript` automatically appears on the reference list if one other entry besides `Wood:color` cross-references it.

The default is compiled into the BibTeX program, but it can be changed on the command line¹ by specifying `--min-crossrefs` together with the desired value. For instance, the article by Mittelbach & Rowley [149] is part of a published proceedings book, and because it is the only article referenced from this book, all information — such as the editor and the book title — is included as part of it. If we had used

```
bibtex --min-crossrefs=1 tlc3
```

we would have gotten two entries, with [149] becoming much shorter and referencing a separate proceedings entry instead. An example of such cross-referencing in the bibliography of this book is [91], which is cross-referenced by eight articles, from [92] to [100]. Using such cross-references in case there are several entries saves space, and is especially useful if all entries are close together, which is true here, because all of them are publications by Donald Knuth.

On the other hand, if you want to avoid separate entries for whole books or proceedings, regardless of the number of entries referencing them (because they involve different authors and are therefore on different pages in the bibliography), set the `--min-crossrefs` option to a suitably large value (e.g., 500), and then each entry contains all the relevant data.

biber/biblatex

The threshold can be set with the biblatex package option `mincrossrefs` or with the biber option `--mincrossrefs`.

A cross-referenced entry must occur later in the database files than every entry that cross-references it. Thus, all cross-referenced entries could be put at the end of the database. Cross-referenced entries cannot themselves cross-reference another entry.

biber/biblatex

These restrictions do not exist when using biber.

You can also use L^AT_EX's `\cite` command inside the fields of your BibTeX entries. This can be useful if you want to reference some other relevant material inside a note field:

```
note = "See Eijkhout \cite{Eijkhout:1991} for more details"
```

However, such usage may mean that you need additional L^AT_EX and BibTeX runs to compile your document properly. This happens if the citation put into the `.bbl` file by BibTeX refers to a key that was not used in a citation in the main document. Thus, L^AT_EX will be unable to resolve this reference in the following run and needs an additional BibTeX and two additional L^AT_EX runs thereafter.

¹In BibTeX8 this option is named `--min_crossrefs` or `-M`.

15.3.8 Managing the BibTeX and biber differences

In the previous sections a number of differences between .bib files for BibTeX and biblatex/biber have been discussed. While it is a rather long list, the effort is usually manageable—in many cases the needed changes are limited to correcting a number of date fields and moving some URLs.

It is, however, a fact that the formats of the entries can be incompatible, not only because biber has different parsing rules but also because many biblatex/biber features and specialities have no counterpart in BibTeX styles.

Two separate .bib files

If one wishes to stay compatible with the BibTeX workflow, there are a number of options: a clean and simple way is to use two .bib files, one “BibTeX only”, one “biblatex only” for the diverging entries. The advantages are that the files can have a clear format and that all biblatex options and commands can be used without problems. The disadvantage is that it requires more maintenance effort.

If using two .bib files is not possible or wanted, follow these guidelines:

- Avoid using, in fields also processed by BibTeX, features that it does not understand, such as the extended name syntax or UTF-8 input.
- Use @preamble to provide fallback definitions for biblatex commands, e.g.,

```
@preamble{"\providecommand\nbhyphen{-}"}
```

- If it is unavoidable to have fields with different content, you can make use of the ability of biber to change and replace fields on the fly by declaring a “source map”. Such a source map is a set of instructions for biber to change some fields. A source map can be given in a document but also in a configuration file.

Example 15-3-5 below shows a simple source map that tells biber to replace the author field with the author-biblatex field if it exists. Entries without this special field stay unchanged. The sample source map also removes the abstract field and so avoids errors due to special characters. The entry used for the example from Figure 15.2 on page 391 contains two different author names and a problematic abstract field that contains a hash, #, and a percent, %. With biblatex and its source map this gives the following output:

```
\usepackage[style=authoryear, uniquename=allfull]{biblatex}
\addbibresource{tlc-ex.bib}
\DeclareSourcemap{
  \maps{
    \map[overwrite]{
      \step[fieldsource=author-biblatex,fieldtarget=author]
      \step[fieldset=abstract,null]%suppress abstract
    }
  }
}
```

The author is Betty Smith

The author is \citenam{sourcemap-test}[given-family]{author}

15-3-5

If the same .bib file is used with BibTeX, it would use “Charles Doe” as the author name.

15.4 Using BibTeX or biber to produce the bibliography

In this section we outline how to create an input, usable by L^AT_EX, from .bib databases, discussed in the previous section. A document typically contains only a subset of the entries stored in such databases, and the bibliography should conform to a certain style with respect to the formatting and the sorting of the entries. Thus, the programs BibTeX and biber have to gather the entries from the keys specified in the document and use the style and sorting options and the database resources as directed by the document.

To enable BibTeX to access these data, the necessary information is written in a previous L^AT_EX run to the .aux file. BibTeX then reads the .aux file (or files if \include is involved) and searches through the specified bibliographic database(s) for the keys,¹ extracts all required entries, and formats them. Formatting these entries is controlled by an associated bibliography style (the .bst file) that contains a set of instructions written in a stack-based language. The latter is interpreted by the BibTeX program.

biber does not use the .aux file to communicate with L^AT_EX; instead, it reads a dedicated control file with the extension .bcf. This is an XML file that is generated by the package biblatex. This control file contains all the formatting instructions needed by biber, so no .bst file is used either.

BibTeX and biber know which fields are required, optional, and ignored for any given entry type (see Table 15.1 on page 386). They issue warnings on the terminal and in the .blg file, such as “author name required”, if something is missing. Their style files can control the typesetting of both the citation string in the main text and the actual bibliography entry.

The procedure for running L^AT_EX and BibTeX or biber is shown schematically in Figure 15.3 on the next page. With BibTeX at least three L^AT_EX runs are necessary — first to produce data for BibTeX, then to load the result from the BibTeX run, and finally to resolve the cross-references to the bibliographical list added by the previous run. With biber and biblatex two L^AT_EX runs are often enough.

As can be seen in the figure, both programs create as main output a file with the extension .bbl that is then read in by L^AT_EX. Depending on the style, this file can have varying content.

With the standard styles and various other styles, BibTeX writes into the .bbl file a standard thebibliography environment as described in Section 15.1. It is possible to include the content of such a .bbl file in your document, if your L^AT_EX document has to be self-contained. It is also a simple matter to manually edit this output from BibTeX to cope with special cases.

With other styles, BibTeX writes a thebibliography environment that contains special commands that require the loading of a supporting package to process and typeset the bibliography. The styles from the jurabib package are a prominent example (but not the only one) that create highly structured .bbl files with a large number of jurabib commands that allow adjusting the formatting of the bibliography and the citations with package options. Other examples are shown in Chapter 16, when we discuss packages supporting special citation conventions.

*Standard L^AT_EX
bibliography
environment*

*Bibliography
environments with
special commands*

¹ If the keys are not unique across the databases, the first match wins with a warning.

- ① Run \LaTeX , which generates from the `\cite` commands a number of `\citation` references in its auxiliary file, `.aux`, or — when using `biblatex` — instructions for `biber` in the `biber` control file, `.bcf`.
- ② Run `BibTeX` or `biber`, which reads the auxiliary file or the control file, looks up the references in a database (one or more `.bib` files), and then writes a file (the `.bbl` file) containing either the formatted references according to the format specified in the style file (the `.bst` file) or the commands needed by `biblatex` to format the bibliography. Warning and error messages are written to the log file (the `.blg` file). Note that neither `BibTeX` nor `biber` ever reads the original \LaTeX source file.
- ③ Run \LaTeX again, which now reads the `.bbl` file containing the bibliographic information.
- ④ Run \LaTeX a third time, resolving all references — may not be necessary with `biblatex`.

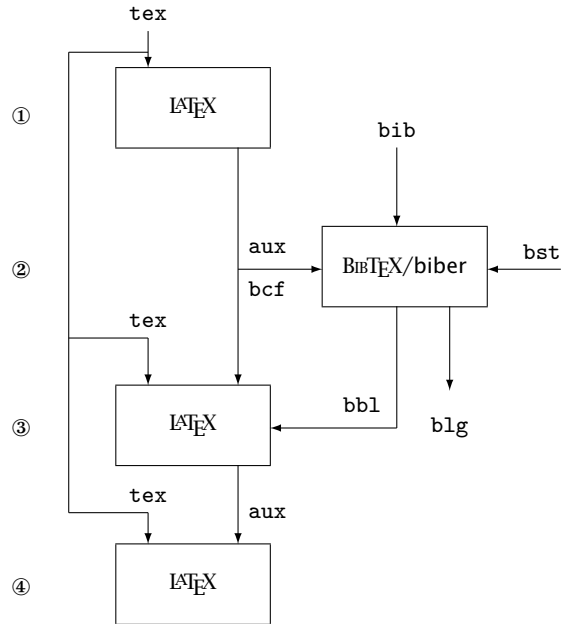

Figure 15.3: Data flow when running `BibTeX` or `biber` and \LaTeX

*.bbl files with only
bibliography data*

If you use `biblatex`, then the `.bbl` file no longer contains a `thebibliography` environment or any typesetting instructions at all, but only a structured, preprocessed, and sorted representation of the bibliography data. These `.bbl` files are no longer loaded at the place where the bibliography is printed, but at the start of the document, which explains why often only two \LaTeX runs are needed to resolve all citations. The task to format and typeset the data is delegated fully to \LaTeX and the `biblatex` package.

We now show in more detail the commands needed in the \LaTeX document to pass the data to the bibliography processors.

```
\bibliography{file-list}
```

*How to select the
BibTeX databases*

To inform `BibTeX` which databases are to be searched to resolve citations, you should specify their names, separated by commas (and *without* the extension `.bib`), as the argument to the command `\bibliography`. This command should be placed at the point where the bibliography should finally appear as the command is also used to typeset the bibliography. This coupling makes it a bit challenging to print more than one bibliography in a document — we discuss this in Section 16.8.

It is, of course, important that all cite keys used in the bibliography databases are unique, because it is otherwise not possible to reliably resolve the citation references when the document is processed.

biber/biblatex

```
\addbibresource[options]{file.bib}
```

With biblatex the databases should be declared in the preamble of the document with the command `\addbibresource`. The mandatory argument is the name of one database *with* the extension `.bib`. If you have more than one `.bib` file, use one `\addbibresource` for each. biber can use URLs to access remote files and is able to resolve patterns. Check the documentation for details.

```
\bibliographystyle{style}
```

With this command you tell BibTeX which style to use for the bibliography. The style refers to a `.bst` file, and the name must be given without the extension. There is no default style, so issuing the command is required; it can be placed in the document or in the preamble. Section 15.7 presents examples produced by a number of standard and nonstandard styles.

How to select the BibTeX style

The style defines also the sorting of the entries. A “nonsorting” BibTeX style by order of first citation as required by the house styles of many publishers is, for example, `unsrt`.

Order by first citation produced with BibTeX

biber/biblatex

biblatex does not make use of `\bibliographystyle` and errors if it detects it. The default biblatex style is a numeric style with alphabetic sorting; other styles and sortings are set through various package options and commands. Some of these options are passed to biber through the control file and affect its processing of the data; others are relevant only for the L^AT_EX compilation.

The package option that most closely matches the concept of a `.bst` style is the key `style`, which takes as a value a bibliography style name like `apa` or `authoryear`. The sorting is typically defined by such a style but can also be changed individually with the option `sorting`. This is described in more detail in Section 16.7.

To select entries from the databases, they need to be cited in the document. Citation commands and their arguments are discussed in more detail in the next chapter, for now it is enough to know that in standard L^AT_EX you can use `\cite` or `\nocite` — with further citation commands provided by loading additional packages.

How to select entries from the database

`\cite` also typesets the citations, while the sole purpose of `\nocite` is to write the keys in its argument into the `.aux` or `.bcf` file so that the associated bibliography information appears in the bibliography even if the publication is otherwise not referred to. Both commands can be used as often as necessary. As a special case, `\nocite{*}` includes all entries of the chosen BibTeX database(s) in the list of references.

biber/biblatex

The biblatex package offers a larger set of citation commands, and their syntax has been extended to accept two optional arguments. They are discussed in Section 16.7.3.

Putting everything together, a sample document for a standard B_BT_EX workflow would look like this:

```
\documentclass{article}
\begin{document}
  \nocite{MR-PQ} ... \cite{LGC97} ... \cite{Knuth-CT-a}

  \bibliographystyle{unsrt} \bibliography{tlc}
\end{document}
```

The .aux file would then contain:

```
\citation{MR-PQ}
\citation{LGC97}
\citation{Knuth-CT-a}
\bibstyle{unsrt}
\bibdata{tlc}
```

Do not
use `\bibdata` by
mistake

Do not confuse these commands with those intended for use in documents. They exist solely to facilitate the internal communication between L^AT_EX and B_BT_EX. If you mistakenly use `\bibdata` instead of `\bibliography`, then L^AT_EX processes your document without failure, but B_BT_EX complains that it does not find any database information in the .aux file.

biber/biblatex

A comparable document using the biber workflow together with the biblatex package would then be:

```
\documentclass{article}
\usepackage[sorting=none]{biblatex}
\addbibresource{tlc.bib}
\begin{document}
  \nocite{MR-PQ} ... \cite{LGC97} ... \cite{Knuth-CT-a}

  \printbibliography
\end{document}
```

Note that in contrast to the standard B_BT_EX workflow, a dedicated command like `\printbibliography` is needed (but not required) in order to print the full bibliography or parts of it. The available commands and their options are described in Section 16.7.8.

It is important to remember that `BibTeX` or `biber` is not required for managing citations (except for packages such as `biblatex` and `jurabib` and those intended for producing multiple bibliographies). You can produce a bibliography without `BibTeX` by providing the bibliographic entries yourself using the syntax described in Section 15.1.

15.5 On-line bibliographies

If you search the Internet, you find a large number of bibliography entries for both primary and secondary publications in free as well as commercial databases. In this section we mention a few free resources on scientific publications that offer bibliographic data in `BibTeX` and some other formats.

Nelson Beebe maintains more than 1400 `BibTeX` databases related to scientific journals and particular scientific topics.¹ These range from “Acta Informatica” and “Ada User Journal” to “X Journal” and “X Resource [journal]”. All are available as `.bib` source files as well as listings in `.html`, `.pdf`, and `.ps` format.

Nelson Beebe's most interesting `.bib` databases, as far as `TeX` is concerned, are the files `texbook1.bib`, `texbook2.bib`, and `texbook3.bib` (articles and books about `TeX`, `METAFONT`, and friends), `type.bib` (a list of articles and books about typography), `gut.bib` (the contents of the French *Cahiers Gutenberg* journal), `komoedie.bib` (the contents of the German *Die TEXnische Komödie* journal), `texgraph.bib` (sources explaining how to make `TeX` and graphics work together), `texjournal.bib` (a list of journals accepting `TeX` as input), `tugboat.bib` (all the articles in *TUGboat*), and `standard.bib` (software standards). The web resources provided by Nelson Beebe also include a series of `BibTeX` styles and many command-line tools for manipulating bibliography data (discussed in Section 15.6.3).

The Collection of Computer Science Bibliographies by Alf-Christian Achilles, containing more than 1.2 million references, can be found at <https://liinwww.ira.uka.de/bibliography/index.html> and at several mirror sites. The data included come from external bibliographical collections like those created by Nelson Beebe. One added-value feature is the search functionality, which allows you to research authors, particular subjects, topics, and other categories. Nearly all of the reference data are available in `BibTeX` format.

Another interesting source is CiteSeer, Scientific Literature Digital Library, developed by Steve Lawrence, which can be found at <https://citeseerx.ist.psu.edu>. Helpful features include extensive search possibilities, context information on publications (e.g., related publications), citations to the document from other publications, statistical information about citations to a citation, and much more.

These examples represent merely a small selection of the vast amount of material found on the Internet. They might prove useful if you are interested in research papers on mathematics, computer science, and similar subjects.

¹The bibliographic databases and support programs for maintaining and manipulating them can be found at <https://www.math.utah.edu/pub/bibnet/> and <https://www.math.utah.edu/pub/tex/bib/>.

15.6 Bibliography database management tools

Because \TeX databases are plain-text files, they can be generated and manipulated with any editor that is able to write ASCII and UTF-8 files. However, with large collections of \TeX entries, this method can get quite cumbersome, and finding information becomes more and more difficult. For this reason people developed tools to help with these tasks.

An overview of programs with a graphical user interface for general database maintenance can be found at https://en.wikipedia.org/wiki/Comparison_of_reference_management_software.

A selection of command-line tools for specific tasks is described in this section. Many of them can be found at <https://ctan.org/tex-archive/biblio/bibtex/utls/>, but do not take Nelson Beebe's tools from there — CTAN has only old versions for some reason.

New products of both types are emerging, so it is probably worthwhile to check out available Internet resources (e.g., https://wiki.openoffice.org/wiki/Bibliographic_Software_and_Standards_Information).

15.6.1 checkcites — Which citations are used, unused, or missing?

It can sometimes be useful to check if all references of a `.bib` file have been cited. For this the small tool `checkcites` from Paulo Cereda and Enrico Gregorio can be used. Its usage is simple. Compile your document as usual and then use

```
checkcites <file>      or      checkcites --backend biber <file>
```

The second call is meant for a document that uses `biblatex` and `biber`.

For a document using the `tlc.bib` file and citing the entries `bschur` and `doody`, this then reports on the terminal unused and unknown references:

```
-----
Report of unused references in your TeX document (that is, references
present in bibliography files, but not cited in the TeX source file)
-----

Unused references in your TeX document: 18
=> LGC97
=> LWC99
=> Knuth-CT-a
=> Knuth:TB10-1-31
...

-----
Report of undefined references in your TeX document (that is, references
cited in the TeX source file, but not present in the bibliography files)
-----

Undefined references in your TeX document: 1
=> doody
```

15.6.2 biblist — Printing BibTeX database files

A sorted listing of all entries in a BibTeX database is often useful for easy reference. Various tools, with more or less the same functionality, are available, and choosing one or the other is mostly a question of taste. In this section we discuss one representative tool, the biblist package written by Joachim Schrod. It can create a typeset listing of (possibly large) BibTeX databases. Later sections show some more possibilities.

To use biblist you must prepare a L^AT_EX document using the article class. Options and packages like twoside, ngerman, or geometry can be added. Given that entries are never broken across columns, it may not be advisable to typeset them in several columns using multicol, however.

The argument of the \bibliography command must contain the names of all BibTeX databases you want to print. With a \bibliographystyle command you can choose a specific bibliography style. By default, all bibliography entries in the database are typeset. However, if you issue explicit \nocite commands (as we did in the example), only the selected entries from the databases are printed. Internal cross-references via the crossref field or explicit \cite commands are marked using boxes around the key instead of resolving the latter.

15-6-1

You must run L^AT_EX, BibTeX, and L^AT_EX. No additional L^AT_EX run is necessary, because the cross-references are not resolved to conserve space. For this reason you will always see warnings about unresolved citations in such a case.

15.6.3 bibclean, etc. — A set of command-line tools

A set of tools to handle even very huge BibTeX databases was developed by Nelson Beebe. The tools can be obtained from <https://ftp.math.utah.edu/pub/bibttools.html> if they are not already on your system.¹ We give a brief description of each of them.

bibclean This C program is a pretty-printer, syntax checker, and lexical analyzer for BibTeX bibliography database files [12]. The program, which runs on Unix,

¹You may have to compile them yourself in that case.

Vax/VMS, and Windows platforms (with `cygwin`), has many options, but in general you can just type

```
bibclean <bibfile(s)> or bibclean <infile> > <outfile> (useful in pipes)
```

For example, when used on the database file `tlc-ex.bib`, the `bibclean` program reports the following possible problem:

```
%% "EX/tlc-ex.bib", line 108: Unexpected value in
                                \enquote{year = "1980ff"}.
```

bibextract This program extracts from a list of `BIBTEX` files those bibliography entries that match a pair of specified regular expressions, sending them to *stdout*, together with all `@preamble` and `@string` declarations. Two regular expressions must be specified: the first to select keyword values (if this string is empty, then all fields of an entry are examined), and the second to further select from the value part of the fields which bibliography entries must be output. Regular expressions should contain only lowercase strings.

For example, the following command extracts all entries containing the word “PostScript” (or some other capitalization) in any of the fields:

```
bibextract "" "postscript" <bibfile(s)> > <new-bibfile>
```

The next command extracts only those entries containing the string `Adobe` in the `author` or `organization` field:

```
bibextract "author|organization" "adobe" <bibfile(s)> > <new-bibfile>
```

Note that one might have to clean the `.bib` files using `bibclean` before `bibextract` finds correct entries. For example, the entry with “TUGboat” in the title is found with

```
bibclean tlc-ex.bib | bibextract "title" "tugboat"
```

Using `bibextract` alone would fail because of the entry containing the line `year={1980ff}`.

citefind and citetags Sometimes you have to extract the entries effectively referenced in your publication from several large `BIBTEX` databases. The Bourne shell scripts `citefind` and `citetags` use the `awk` and `sed` tools to accomplish that task.

First, `citetags` extracts the `BIBTEX` citation keys from the `TEX` source or `.aux` files and sends them to the standard output *stdout*. There, `citefind` picks them up and tries to find the given keys in the `.bib` files specified. It then writes the resulting new bibliography file to *stdout*. For instance,

```
citetags *.aux | citefind - <bibfile(s)> > <outfile>
```

Nelson Beebe also developed the `showtags` package, which adds the citation key to a bibliography listing. In other words, it does a similar job to `biblist` as shown in Example 15-6-1 on page 415.

15-6-2

15.6.4 Using biber as a tool

`biber` not only can be used to prepare a bibliography for a document, but it can also replace various of the tools described above.

Extracting entries used by a document

The scripts `citefind` and `citetags` described above extract the references used by a document from the `.aux` file and so target the `LaTeX` workflow. To get the references from the `.bcf` control file created for `biber`, `biber` can be used with the option `--output-format` to get a `.bib` file instead of a `.bbl`.

```
biber --output-format=bibtex <file>
```

This creates a file `file_biber.bib` that contains only the entries needed for the document `file.tex`, which created `file.bcf`. Entries required to resolve cross-references are included too.

By using a source map in the document, this can also be used to filter the entries with regular expressions or other conditions. The following document for example suppresses all entries whose key does not contain `Knuth` or `kant`:

```
\documentclass{article}
\usepackage{biblatex}
\addbibresource{tlc.bib}
\DeclareSourcemap{
  \maps[datatype=bibtex]{
    \map{%
      \step[fieldsource=entrykey,notmatch=\regex{Knuth|kant},final]%
      \step[entrynull]}}%
\nocite{*}
\begin{document} \printbibliography \end{document}
```

Validation

By using the option `--validate-datamodel` it is possible to validate one or more `.bib` files:

```
biber --tool --validate-datamodel tlc.bib tlc-ex.bib
```

This then reports on the terminal beside other information:

```
WARN - Datamodel: Entry 'G-G' (tlc.bib): Missing mandatory field 'author'
WARN - Datamodel: Entry 'oddity' (tlc-ex.bib): Invalid value of field 'year'
        must be datatype 'datepart' - ignoring field
```

Normalization and rewriting of entries

`biber` can also be used to clean up and normalize the entries of a `.bib` file, e.g.,

```
biber --tool --output-align tlc.bib
```

This creates a `tlc_bibertool.bib` file in which surrounding quotes are converted to braces, all field names are uppercased, their order is unified, and their values are aligned. `biber` also changes field names like `journal` to `journaltitle` and moves year and month to date. So, for example, the entry `Knuth:TB10-1-31` will then have this format:

```
@ARTICLE{Knuth:TB10-1-31,
  AUTHOR      = {Knuth, Donald E.},
  DATE        = {1989-04},
  ISSN        = {0896-3207},
  JOURNALTITLE = {TUGboat},
  NUMBER      = {1},
  PAGES        = {31--36},
  TITLE       = {{Typesetting Concrete Mathematics}},
  VOLUME      = {10},
}
```

15.7 Formatting the bibliography with styles

Now that we know how to produce `BIBTEX` database entries and manipulate them using various management tools, it is time to discuss the main purpose of the `BIBTEX` and `biber` programs: to generate a bibliography containing the entries referenced in a document in a format conforming to a set of conventions.

We first discuss the use of existing `BIBTEX` styles and present example results produced by a number of standard and nonstandard styles. We then show how the `custom-bib` package makes it possible to produce customized `BIBTEX` styles for nearly every requirement with ease. We continue by discussing how styles are set when using the `biblatex` package, present an overview of existing `biblatex` styles, and finish with a number of examples. The customization of `biblatex` styles are discussed in Section 16.7.

15.7.1 A collection of BibTeX style files

Various organizations and individuals have developed style files for BibTeX that correspond to the house style of particular journals or editing houses. Nelson Beebe has collected a large number of such BibTeX styles. For each style he provides an example file, which allows you to see the effect of using the given style.¹ Some of the BibTeX styles — for instance, `authordate(i)`, `jmb`, and `named` — must be used in conjunction with their accompanying L^AT_EX packages (as indicated in Tables 15.7 to 15.9 on pages 420–423) to obtain the desired effect.

You can also customize a bibliography style, by making small changes to one of those in the table. Alternatively, you can generate your own style by using the `custom-bib` program (as explained in Section 15.7.2 on page 426).

In theory, it is possible to change the appearance of a bibliography by simply using another BibTeX style. In practice, there are a few restrictions because the BibTeX style interface was augmented by some authors so that their styles need additional support from within L^AT_EX. You are going to see several such examples in Chapter 16. For instance, all the author-date styles need a special L^AT_EX package such as `natbib` or `harvard` to function, and the BibTeX styles for `jurabib` work only if that package is loaded.

On the whole, the scheme works quite well, and we prove it in this section by showing the results of applying different BibTeX styles (plus their support packages if necessary) without otherwise altering the sample document. For this we use the familiar database from Figure 15.1 on page 382 and cite five publications from it: an article and a book by Donald Knuth, which shows us how different publications by the same author are handled; the manual from the Free Software Foundation, which is an entry without an author name; the unpublished entry with many authors and the special BibTeX string “and others”; and a publication that is part of a proceedings so that BibTeX has to include additional data from a different entry.

In our first example we use the standard `plain` BibTeX style, which means we use the following input:

```
\bibliographystyle{plain}
\nocite{Knuth:TB10-1-31,GNUMake,MR-PQ,Knuth-CT-a,test97}
\bibliography{tlc,tlc-ex}
```

To produce the final document, the example L^AT_EX file has to be run through L^AT_EX once to get the citation references written to the `.aux` file. Next, BibTeX processes the generated `.aux` file and reads the relevant entries from the BibTeX databases `tlc.bib` and `tlc-ex.bib`. The name of the bibliography style to use for formatting and sorting is specified with the command `\bibliographystyle` in the L^AT_EX source and picked up by BibTeX via the `.aux` file. The results are then placed into a `.bbl` file for further processing by L^AT_EX. Finally, L^AT_EX is run twice more — first to load the `.bbl` file and again to resolve all references.² A detailed explanation of this procedure was given in Section 15.4 on page 409, where you also find a graphical representation of the data flow (Figure 15.3).

¹See Appendix C to find out how you can obtain these files from one of the T_EX archives if they are not already on your system.

²In fact, for this example only one run is necessary — there are no cross-references to resolve because we used `\nocite` throughout.

<i>Style Name</i>	<i>Description</i>
<code>abbrv.bst</code>	Standard BibTeX style
<code>abbrvnat.bst</code>	natbib variant of abbrv style
<code>abstract.bst</code>	Modified alpha style with <code>abstract</code> keyword
<code>acm.bst</code>	Association for Computing Machinery BibTeX style
<code>agsm.bst</code>	Australian government publications BibTeX style; needs the <code>harvard</code> or <code>natbib</code> package
<code>agu.bst</code>	American Geophysical Union BibTeX style
<code>alpha.bst</code>	Standard BibTeX style
<code>amsalpha.bst</code>	alpha-like BibTeX style for $\mathcal{A}\mathcal{M}\mathcal{S}$ -TeX
<code>amsplain.bst</code>	plain-like BibTeX style for $\mathcal{A}\mathcal{M}\mathcal{S}$ -TeX (numeric labels)
<code>annotate.bst</code>	Modified alpha BibTeX style with <code>annotate</code> keyword
<code>annotation.bst</code>	Modified plain BibTeX style with <code>annotate</code> keyword
<code>apa.bst</code>	American Psychology Association BibTeX style
<code>apalike.bst</code>	Variant of <code>apa</code> BibTeX style; needs the <code>apalike</code> support package
<code>apalike2.bst</code>	Variant of <code>apalike</code> BibTeX style
<code>astron.bst</code>	<i>Astronomy</i> BibTeX style
<code>authordate<i>i</i>.bst</code>	<i>i</i> =[1,4]; series of BibTeX styles producing author-date reference list; all of them need the <code>authordate1-4</code> support package
<code>bbs.bst</code>	<i>Behavioral and Brain Sciences</i> BibTeX style

Table 15.7: Selected BibTeX style files (A–B)

The `plain` style has numeric labels (in brackets), and the entries are alphabetically sorted by author, year, and title. In the case of the GNU manual the organization was used for sorting. This gives the following output:

Table 15.8: Selected BibTeX style files (C–J)

By replacing `plain` with `abbrev` we get a similar result. Now, however, the entries are more compact, because first names, months, and predefined journal names (Table 15.6 on page 403) are abbreviated. For instance, `ibmjrd` in the second reference now gives “IBM J. Res. Dev.” instead of “IBM Journal of Research and Development”.

With the standard BibTeX style `unsrt` we get the same result as with the `plain` style, except that the entries are printed in order of first citation, rather than being sorted.¹ The standard sets of styles do not contain a combination of `unsrt` and `abbrv`, but if necessary, it would be easy to integrate the differences between `plain` and `abbrv` into `unsrt` to form a new style.

15-7-3

The standard style `alpha` is again similar to `plain`, but the labels of the entries are formed from the authors' names and the year of publication. The slightly strange label for the GNU manual is because the entry contains a `key` field from which the first three letters are used to form part of the label. Also note the interesting label produced for the reference with more than three authors. The publications are sorted, with the label being used as a sort key, so that now the GNU manual moves to fourth place.

15-7-4

¹In this and all following bibliography examples we suppress the heading that is normally placed in front of entries to save some space.

<i>Style Name</i>	<i>Description</i>
<code>kluwer.bst</code>	Kluwer Academic Publishers BibTeX style
<code>named.bst</code>	BibTeX style with [author(s), year] type of citation; requires the named support package
<code>namunsrt.bst</code>	Named variant of <code>unsrt</code> BibTeX style
<code>nar.bst</code>	<i>Nucleic Acid Research</i> BibTeX style; this style needs the nar support package
<code>nature.bst</code>	<i>Nature</i> BibTeX style; this style requires the nature support package
<code>newapa.bst</code>	Modification of <code>apalike.bst</code> ; needs the newapa support package
<code>newcastle.bst</code>	Newcastle University BibTeX style; to be used with natbib
<code>noTeX.bst</code>	Style to generate HTML output instead of TeX input

Table 15.9: Selected BibTeX style files (K–N)

Many BibTeX styles implement smaller or larger variations of the layouts produced by the standard styles. For example, the `phaip` style for American Institute of Physics journals implements an unsorted layout (i.e., by order of first citation) but omits article titles, uses abbreviated author names, and uses a different structure for denoting editors in proceedings. Note that the entry with more than three authors has now been collapsed, showing only the first one.

- [1] D. E. Knuth, TUGboat **10**, 31 (1989).
- [2] Free Software Foundation, Boston, Massachusetts, *GNU Make, A Program for Directing Re-compilation*, 2000.

- [5] M. Goossens et al., Ambiguous citations, Submitted to the IBM J. Res. Dev., 1997.

15-7-5

Many of the journal and publisher styles, such as `phaip` used above, are not part of the standard L^AT_EX distributions but available only from the journal or publisher websites. They may also be stored on CTAN but often not in their latest version. Thus, if you intend to publish in a specific journal, check out the website of the publisher to make sure you use their current BibTeX style file and not an obsolete version.

If we turn to styles implementing an author-date scheme, the layout usually changes more drastically. For instance, numeric labels are normally suppressed (after

Table 15.10: Selected BibTeX style files (P–U)

all, the lookup process is by author). The `chicago` style, for example, displays the author name or names in abbreviated form (first name reversed), followed by the date in parentheses. In addition, we see yet another way to handle the editors in proceedings, and instead of the word “pages”, we get “pp.” For this example we loaded the `natbib` package to enable author-date support.

Goossens, M., B. User, J. Doe, et al. (1997). Ambiguous citations. Submitted to the IBM J. Res. Dev.

Knuth, D. E. (1986). *The T_EXbook*, Volume A of *Computers and Typesetting*. Reading, MA, USA: Addison-Wesley.

Knuth, D. E. (1989, April). Typesetting Concrete Mathematics. *TUGboat* 10(1), 31–36.

Mittelbach, F. and C. Rowley (1992). The pursuit of quality: How can automated typesetting achieve the highest standards of craft typography? In C. Vanoirbeek and G. Coray (Eds.), *EP92—Proceedings of Electronic Publishing, '92*, Cambridge, pp. 261–273. Cambridge University Press.

As a final example we present another type of layout that is implemented with the help of the `jurabib` package. Because more customizing is necessary, we show the input used once more. The trick used to suppress the heading is *not* suitable for use in real documents because the space around the heading would be retained!

```
\usepackage[bibformat=ibidem]{jurabib}
\bibliographystyle{jurabib} \jbuseidemhrule % use default rule
\renewcommand\refname{} % suppress heading for the example
\nocite{Knuth:TB10-1-31,GNUMake,MR-PQ,Knuth-CT-a,test97,LGC97}
\bibliography{t1c,t1c-ex}
```

This produces a layout in which the author name is replaced by a rule if it has been listed previously. In the case of multiple authors, the complete list has to be identical (see the first two entries). Also, for the first time, the International Standard Book Number (ISBN) and International Standard Serial Number (ISSN) are shown when present in the entry. If you look closely, you see many other smaller and larger differences. For example, this is the first style that does not convert titles of articles and proceeding entries to lowercase but rather keeps them as specified in the database.

Because the original application field for `jurabib` was law citations, it is one of the few \LaTeX styles that do not provide default strings for the journals listed in Table 15.6 on page 403; if you need any of them, you have to provide them yourself. \LaTeX warns you about the missing string in this case. You can then provide a definition for it in the database file or, if you prefer, in a separate database file that is loaded only if necessary.

15-7-7

If you wonder about the strange placement of the GNU Make manual entry, recall that this entry has no author but has a key specified, which is the reason for this placement when using the `jurabib` style.

<i>Requirement</i>	<i>Example</i>
Full name surname last	Donald Ervin Knuth/Michael Frederick Plass
Full name surname first	Knuth, Donald Ervin/Plass, Michael Frederick
Initials and surname	D. E. Knuth/M. F. Plass
Surname and initials	Knuth, D. E./Plass, M. F.
Surname and dotless initials	Knuth D E/Plass M F
Surname and concatenated initials	Knuth DE/Plass MF
Surname and spaceless initials	Knuth D.E./Plass M.F.
Only first author reversed with initials	Knuth, D. E./M. F. Plass
Only first author reversed with full names	Knuth, Donald Ervin/Michael Frederick Plass

Table 15.11: Requirements for formatting names

15.7.2 custom-bib — Generate \LaTeX styles with ease

So far, we have discussed how to influence the layout of the bibliography by using different bibliography styles. If a particular \LaTeX style is recommended for the journal or publisher you are writing for, then that is all that is necessary. However, a more likely scenario is that you have been equipped with a detailed set of instructions, which tells you how references should be formatted, but without pointing you to any specific \LaTeX style — a program that may not even be known at the publishing house.

Of course, hunting for an existing style that fits the bill or can be adjusted slightly to do so is an option, but given that there are usually several variations in use for each typographical detail, the possibilities are enormous, and thus the chances of finding a suitable style are remote.

Consider, for example, the nine common requirements for presenting author names in Table 15.11. Combining these with a specification for the separation symbol to use (e.g., comma, semicolon, slash), the fonts to use for author names (i.e., roman, bold, small capitals, italic, other), and perhaps a requirement for different fonts for surname and first names, you end up with more than 500 different styles — just for presenting author names in the bibliography. Clearly, this combinatorial explosion cannot be managed by providing predefined styles for every combination.

Faced with this problem, Patrick Daly, the author of `natbib`, started in 1993 to develop a system that is capable of providing customized \LaTeX styles by collecting answers to questions like the above (more than 70!) and then building a customized `.bst` file corresponding to the answers.

The system works in two phases: (1) a collection phase in which questions are interactively asked and (2) a generation phase in which the answers are used to build the \LaTeX style. Both phases are entirely done by using \LaTeX and thus can be carried out on any platform without requiring any additional helper program.

The collection is started by running the program `makebst.tex` through \LaTeX and answering the questions posed to you. Most of the questions are presented in

the form of menus that offer several answers. The default answer is marked with a * and can be selected by simply pressing *<return>*. Other choices can be selected by typing the letter in parentheses in front of the option. Selecting a letter not present produces the default choice.

Initializing the system

We now walk you through the first questions, which are somewhat special because they are used to initialize the system. Each time we indicate the suggested answer.

Do you want a description of the usage? (NO)

Replying with y produces a description of the procedure (as explained above); otherwise, the question has no effect.

Enter the name of the MASTER file (default=merlin.mbs)

Here the correct answer is *<return>*. The default merlin.mbs is currently the only production master file available, though this might change one day.

Name of the final OUTPUT .bst file? (default extension=bst)

Specify the name for your new BibTeX style file, without an extension — for example, ttct (Tools and Techniques for Computer Typesetting series). As a result of completing the first phase, you then receive a file called ttct.dbj from which the BibTeX style file ttct.bst is produced in the second phase.

Give a comment line to include in the style file.
Something like for which journals it is applicable.

Enter any free-form text you like, but note that a *<return>* ends the comment. It is carried over into the resulting files and can help you at a later stage to identify the purpose of this BibTeX style.

Do you want verbose comments? (NO)

If you enter y to this question, the context of later questions is shown in the following form:

```
<<STYLE OF CITATIONS:
...
>>STYLE OF CITATIONS:
```

Whether this provides any additional help is something you have to decide for yourself. The default is not to provide this extra information.

Name of language definition file (default=merlin.mbs)

If you are generating a BibTeX style for a language other than English, you can enter the name of the language here. Table 15.12 on the opposite page lists currently supported languages. Otherwise, reply with `<return>`.

Include file(s) for extra journal names? (NO)

By answering y you can load predefined journal names for certain disciplines into the BibTeX style. You are then asked to specify the files containing these predefined names (with suitable defaults given).

This concludes the first set of questions for initializing the system. What follows are many questions that offer choices concerning layout and functional details. These can be classified into three categories:

Citation scheme The choice made here influences later questions. If you choose author-date support, for example, you get different questions than if you choose a numerical scheme.

Extensions These questions are related to extending the set of supported BibTeX fields, such as whether to include a `url` field.

Typographical details You are asked to make choices about how to format specific parts of the bibliographical entries. Several of the choices depend on the citation scheme used.

While it is possible to change your selections in the second phase of the processing (or to start all over again), it is best to have a clear idea about which citation scheme and which extensions are desired before beginning the interactive session. The typographical details can be adjusted far more easily in the second phase if that becomes necessary. We therefore discuss these main choices in some detail.

Selecting the citation scheme

The citation scheme is selected by answering the following question:

STYLE OF CITATIONS:

- (*) Numerical as in standard LaTeX
- (a) Author-year with some non-standard interface
- (b) Alpha style, Jon90 or JWB90 for single or multiple authors
- (o) Alpha style, Jon90 even for multiple authors
- (f) Alpha style, Jones90 (full name of first author)
- (c) Cite key (special for listing contents of bib file)

The default choice is “numerical”. If you want to produce a style for the author-date scheme, select a (and disregard the mentioning of “nonstandard interface”). For alpha-style citations, use either b, o, or f depending on the label style you prefer. Choice c is of interest only if you want to produce a style for displaying BibTeX databases, so do not select it for production styles.

catalan	Language support for Catalan	italian	Language support for Italian
dansk	Language support for Danish	norsk	Language support for Norwegian
dutch	Language support for Dutch	polski	Language support for Polish
esperant	Language support for Esperanto	portuges	Language support for Portuguese
finnish	Language support for Finnish	slovene	Language support for Slovene
french	Language support for French	spanish	Language support for Spanish
german	Language support for German		

Table 15.12: Language support in custom-bib

If the default (i.e., a numerical citation scheme) was selected, the follow-up question reads:

```
HTML OUTPUT (if non author-year citations)
(*) Normal LaTeX output
(h) Hypertext output, in HTML code, in paragraphs
(n) Hypertext list with sequence numbers
(k) Hypertext with keys for viewing databases
```

Select the default. All other choices generate BibTeX styles that produce some sort of HTML output (which needs further manipulation before it can be viewed in browsers). This feature is considered experimental.

If you have selected an author-date citation scheme (i.e., a), you are rewarded with a follow-up question for deciding on the support interface from within L^AT_EX:

```
AUTHOR--YEAR SUPPORT SYSTEM (if author-year citations)
(*) Natbib for use with natbib v5.3 or later
(o) Older Natbib without full authors citations
(l) Apalike for use with apalike.sty
(h) Harvard system with harvard.sty
(a) Astronomy system with astron.sty
(c) Chicago system with chicago.sty
(n) Named system with named.sty
(d) Author-date system with authordate1-4.sty
```

The default choice, natbib, is usually the best, offering all the possibilities described in Sections 16.3.2 and 16.4.1. The option o should *not* be selected. If you have documents using citation commands from, say, the harvard package (see Example 16-3-4 on page 490), the option h would be suitable. For the same reason, the other options might be the right choice in certain circumstances. However, for document portability, natbib should be the preferred choice. Note in particular that some of the other packages mentioned in the options are no longer distributed in the mainstream L^AT_EX installation.

Determining the extensions supported

Besides supporting the standard B \TeX entry types (Table 15.1 on page 386) and fields (Tables 15.3/4 on pages 388–389), `makebst.tex` can be directed to support additional fields as optional fields in the databases so that they are used if present. Some of these extensions are turned off by default, even though it makes sense to include them in nearly every B \TeX style file.

LANGUAGE FIELD

- (*) No language field
- (l) Add language field to switch hyphenation patterns temporarily

Replying with `l` greatly helps in presenting foreign titles properly. If you additionally specify a nonstandard language key in your `.bib` files in all entries that have foreign titles or notes, then such entries temporarily switch to the specified language, using Babel's `\selectlanguage` command. If you use the `.bib` file with a different style that does not know about language, the key is ignored as usual. Thus, a deviation from the default is suggested.

ANNOTATIONS:

- (*) No annotations will be recognized
- (a) Annotations in `annotate` field or in `.tex` file of `citekey` name

Choosing `a` integrates support for an `annotate` field in the `.bst` file as well as support for including annotations stored in files of the form `<citekey>.tex`. However, in contrast to `jurabib`, which also offers this feature, the inclusion cannot be suppressed or activated using a package option. Given that you quite likely want this feature turned on and off depending on the document, you might be best served by using two separate B \TeX styles differing only in this respect.

The nonstandard field `eid` (electronic identifier) is automatically supported by all generated styles. The fields `doi`, `isbn`, and `issn` are included by default but can be deselected. Especially for supporting the REV \TeX package from the American Physical Society, a number of other fields can be added.

Finally, support for URLs can be added by answering the following question with something different from the default:

URL ADDRESS: (without REV \TeX fields)

- (*) No URL for electronic (Internet) documents
- (u) Include URL as regular item block
- (n) URL as note
- (l) URL on new line after rest of reference

We suggest including support for URLs because references to electronic resources are common now. In the bibliography the URL is tagged with `\urlprefix\url{field-value}`, with default definitions for both commands. By loading the `url` package, better line breaking can be achieved.

As one of the last questions you are offered the following choice:

COMPATIBILITY WITH PLAIN TEX:

- (*) Use LaTeX commands which may not work with Plain TeX
- (t) Use only Plain TeX commands for fonts and testing

We strongly recommend retaining the default! L^AT_EX 2_ε is more than three decades old, and NFSS should have found its way into every living room. Besides, the plain T_EX commands (`\rm`, `\bf`, and so on) are no longer officially part of L^AT_EX. They may be defined by a document class (for compatibility reasons with L^AT_EX 2.09) — but then they may not. Thus, choosing the obsolete syntax may result in the B_BT_EX style not functioning properly in all circumstances.

 Always choose the default option here: the other may not work reliably!

Note that the questions about the extensions are mixed with those about typographical details and do not necessarily appear in the order presented here.

Specifying the typographical details

The remaining questions (of which there are plenty) concern typographical details, such as formatting author names, presenting journal information, and many more topics. As an example we show the question block that deals with the formatting of article titles:

TITLE OF ARTICLE:

- (*) Title plain with no special font
- (i) Title italic (`\em`)
- (q) Title and punctuation in single quotes (`'Title,'` ..)
- (d) Title and punctuation in double quotes (`\enquote{Title,}` ..)
- (g) Title and punctuation in guillemets (`<<Title,>>` ..)
- (x) Title in single quotes (`'Title',` ..)
- (y) Title in double quotes (`\enquote{Title},` ..)
- (z) Title in guillemets (`<<Title>>,` ..)

If you make the wrong choice with any of them, do not despair. You can correct your mistake in the second phase of the processing as explained below.

Generating the B_BT_EX style from the collected answers

The result of running `makebst.tex` through L^AT_EX and answering all these questions is a new file with the extension `.dbj`. It contains all your selections in a special form suitable to be processed by DOCSTRIP, which in turn produces the final B_BT_EX style (see Section 17.2 for a description of the DOCSTRIP program). Technically speaking, a B_BT_EX bibliographic style file master (`merlin.mbs` by default) contains alternative coding that depends on DOCSTRIP options. By choosing entries from the interactive menus discussed above, some of this code is activated, thereby providing the necessary customization.

If you specified `ttct` in response to the question for the new `.bst` file, for example, you would now have a file `ttct.dbj` at your disposal. Hence, all that is

necessary to generate the final \LaTeX style `ttct.bst` is to run

```
latex ttct.dbj
```

The content of the `.dbj` files generated from the first phase is well documented and presented in a form that makes further adjustments quite simple. Suppose you have answered `y` in response to the question about the title of articles on the previous page (i.e., use double quotes around the title), but you really should have replied with `d` (use double quotes around title and punctuation). Then all you have to do is open the `.dbj` file with a text editor and search for the block that deals with article titles:

```
%-----
%TITLE OF ARTICLE:
%  %: (def) Title plain
% tit-it,%: Title italic
% tit-qq,qt-s,%: Title and punctuation in single quotes
% tit-qq,%: Title and punctuation in double quotes
% tit-qq,qt-g,%: Title and punctuation in guillemets
% tit-qq,qt-s,qx,%: Title in single quotes
% tit-qq,qx,%: Title in double quotes
% tit-qq,qt-g,qx,%: Title in guillemets
%-----
```

Changing the behavior then entails nothing more than uncommenting the line you want and commenting out the line currently selected:

```
%-----
%TITLE OF ARTICLE:
%  %: (def) Title plain
% tit-it,%: Title italic
% tit-qq,qt-s,%: Title and punctuation in single quotes
% tit-qq,%: Title and punctuation in double quotes
% tit-qq,qt-g,%: Title and punctuation in guillemets
% tit-qq,qt-s,qx,%: Title in single quotes
% tit-qq,qx,%: Title in double quotes
% tit-qq,qt-g,qx,%: Title in guillemets
%-----
```

After that, rerun the file through \LaTeX to obtain an updated \LaTeX style.

15.7.3 An overview of biblatex styles

In the final section of this chapter we present a fairly comprehensive overview of biblatex styles in the form of short examples to help you find a style that fits your requirements, or at least one that is close and requires only minor customizations. We start with a short description of how styles are implemented and how the styles have been classified.

The main package option is the key `style`, which takes a *name* as its value. If given, `biblatex` loads the file *name*.`bbx`, which contains the settings for the formatting of the bibliography, and the file *name*.`cbx`, which contains the settings for the formatting of the citations. Both files must exist. If present, *name*.`dbx` is loaded too: this file can contain settings that extend the data model and, for example, declare new entry types or fields. Alternatively, you can set styles for citations and the bibliography independently, using the keys `citestyle` and `bibstyle`; then only a `.cbx` or `.bbx` is loaded. By default `biblatex` loads the `numeric` style.

Loading a style

The style files contain \LaTeX code and definitions that are used during the \LaTeX compilation. Various aspects can be adjusted through options, configuration commands, or with redefinitions, both in documents or when creating a new style based on an existing style. This makes them much more flexible than \BibTeX styles.

The following two examples demonstrate this. They are both based on the style `authoryear`, but the second has a number of changes made for illustration purposes — not necessarily for the better! First the default version:

References

- Knuth, Donald E. (1986). *The \TeX book*. Vol. A. Computers and Typesetting. Reading, MA, USA: Addison-Wesley, pp. ix + 483. ISBN: 0-201-13447-0.
- (Apr. 1989). “Typesetting Concrete Mathematics”. In: *TUGboat* 10.1, pp. 31–36. ISSN: 0896-3207.

15-7-8

```
\usepackage[style=authoryear]{biblatex}
\addbibresource{t1c.bib}

\nocite{Knuth:TB10-1-31,Knuth-CT-a}
\printbibliography
```

In the second example we suppress the dashes and the ISBN, use initials instead of full author names, alter the format of dates, change the sorting, and adapt the title and the punctuation. We also declare that the overall document language is German (through the call to `babel`) — this affects not only the heading but also the prefix of the page numbers. Note that making such changes may require you to rerun `biber`. In other words, some take effect only if the `.bbl` file is regenerated, e.g., changing the sorting typically requires a reprocessing of the bibliography input.

Literatur

- Knuth, D. E. (1989-04); „Typesetting Concrete Mathematics“; in: *TUGboat* 10.1, S. 31–36.
- Knuth, D. E. (1986); **The \TeX book**; Bd. A; Computers and Typesetting; Reading, MA, USA: Addison-Wesley, S. ix + 483.

15-7-9

```
\usepackage[ngerman]{babel}
\usepackage{csquotes}
\usepackage[style=authoryear,
  date=iso,dashed=false,isbn=false,
  sorting=none,giveninits]{biblatex}
\DeclareFieldFormat{title}{\mkbibbold{#1}}
\renewcommand\newunitpunct{%
  \addsemicolon\addspace}
\addbibresource{t1c.bib}

\nocite{Knuth:TB10-1-31,Knuth-CT-a}
\printbibliography
```

This flexibility can make it difficult to choose a suitable style as starting point, because it is not always clear which parts are easy to adapt and which not. A rule of thumb: changing the order of fields is more difficult than adapting fonts and punctuation.

How to choose a style

Classification of
styles

We now present various packages that offer one or more biblatex styles. The list is restricted to packages available on CTAN — more can be found on the Internet or in local installations. The packages have been roughly classified into the following six categories:

Collections of generic styles (*starting on page 435*) Bundles that provide flexible styles with various options and interfaces to adapt them to local requirements.

Implementation of style guides (*starting on page 439*) Bundles that implement a style as promoted by style manuals like the *Publication Manual of the American Psychological Association (APA)* [6] or *The Chicago Manual of Style* [40].

University styles (*starting on page 445*) Bundles that implement the requirements of some university or faculty.

Journal styles (*starting on page 455*) Bundles implementing the style requirements of some journal.

Extensions (*starting on page 461*) Bundles whose main purpose is to extend the data model and to add new field or entry types.

Other styles (*starting on page 464*) These are bundles not fitting in one of the other categories.

Notes
on the following
biblatex samples

For every bundle we start with a short description and a rough classification of the citation systems it supports. We then list the names of the styles it offers: typically both a citation and the bibliography style is provided, and the names can be used with the `style` key, but in some cases only a citation or bibliography style exists, which can be set only with `citestyle` or `bibstyle` — these are listed separately. If `.bbx` and `.cbx` files contain only internal code (for example, `standard.bbx`), then they are not listed, because they are not meant to be used directly in a document.

This is then followed by sample output of a representative selection of the bundle styles (but not necessarily from *all* styles of the bundle). With a few exceptions — as noted in the bundle descriptions — the examples all use the same preamble, i.e.,

```
\usepackage[style={style}]{biblatex}
\addbibresource{tlc-biblatex-special.bib}
```

The entries in the `tlc-biblatex-special.bib` file are based on existing entries from `biblatex-examples.bib`,¹ but names, titles, and annotations have been shortened to save space.

The document body contains four citations: the first is to an article with two authors, then we reference the same book twice to show how the style handles such repetitions, and finally we cite another work of the same author to exhibit how this is formatted in the bibliography — some styles use dashes, others abbreviations like “ders.” (short for the German word “derselbe”) or “idem”, yet others simply repeat

¹This is a sample `.bib` file provided by the biblatex package.

the author name. We use `\cite` for the first reference (to show what that command does) and `\textcite` for the remaining ones, because this command typically gives footnotes with verbose styles and so gives a better impression of the styles.¹

The text is wrapped in a `\textcolor` command so that it appears in blue, which helps in distinguishing main text from bibliography list output, given that we suppress the list header. After the citations the bibliography is printed (without a heading to save space). Thus, the body for each example looks as follows:

```
\textcolor{blue}{See \cite{zar2099}           % Show what \cite does compared to
and \textcite[4-8]{cole1983}             % \textcite for the other references
and again                               % Check how a repeat and the same
\textcite{cole1983,cole1995}}           % author with a different work are handled
\printbibliography[heading=none]
```

15.7.4 Generic styles

The bundles in this category provide a large variety of standard style types with various options and interfaces to adapt them to local requirements. Two prominent examples are the `biblatex` bundle itself and the `biblatex-ext` bundle. The styles are kept up-to-date and are good starting points if you want to create your own style or want to learn what is needed to create a style. They are loaded and then modified by many other styles.

biblatex *Philip Kime, Philipp Lehman* The `biblatex` package comes with a large number of easy-to-customize styles. There is a matching bibliography style for every citation style, but note that many bibliography styles are only small wrappers around a base style. For example, the bibliography style `authortitle-comp` loads the `authortitle` style. So these styles differ only in the formatting of the citation.

Citation systems: various

Styles: `alphabetic`, `alphabetic-verb`, `authortitle`, `authortitle-comp`, `authortitle-ibid`, `authortitle-icomp`, `authortitle-tcomp`, `authortitle-terse`, `authortitle-ticomp`, `authoryear`, `authoryear-comp`, `authoryear-ibid`, `authoryear-icomp`, `debug`, `draft`, `numeric`, `numeric-comp`, `numeric-verb`, `reading`, `verbose`, `verbose-ibid`, `verbose-inote`, `verbose-note`, `verbose-trad1`, `verbose-trad2`, `verbose-trad3`

15.7.5 Implementations of style guides

The bundles in this category implement styles promoted by important style manuals. They often contain quite complex styles with fixed settings, implemented with low-level coding. Some of them require special loading or nonstandard settings in the document, so the documentation should be consulted before use. They are good styles if used as is, but changing them can be difficult and requires some programming skills.

biblatex-apa Philip Kime Style implementing the APA (American Psychological Association) style.

Citation system: author-date *Style:* apa

Style sample:

- See Zar and Lau, 2099 and Cole (1983, pp. 4–8) and again Cole (1983, 1995)
- apa Cole, S. T. (1983). *The cool works of Sam Ted Cole*. Vol. 72. *Life story, or Biographical sketches* (K. Cob, J. Eng, & W. J. Bate, Eds.; Vol. 7). Rout and Paul.
One (partial) volume of a multivolume book.
- Cole, S. T. (1995). *Remake of life story*.
- Zar, Z. C., & Lau, A. D. (2099). Algebra. *Theory*, 12, 423–491
An article with eprint and eprinttype fields.

15-7-27

biblatex-chicago David Fussner Styles implementing the specifications of *The Chicago Manual of Style*; see windycity for an alternative. To load the styles use the biblatex-chicago package and its options authordate, authordate-trad, or notes, e.g.,

```
\usepackage[authordate]{biblatex-chicago}
```

Citation systems: author-date, verbose

Styles: chicago-authordate, chicago-authordate-trad, chicago-notes

Style samples:

biblatex-mla *James Clawson* Style implementing the specifications of the Modern Language Association (MLA) handbook. The style recommends using `\autocite` as standard citation command.

Citation system: author-title

Styles: mla, mla-strict, mla7

Citation style: mla-footnotes

Style sample:

See Zar and Lau and Cole, *Life story* 4-8 and again *Life story*; *Remake*

Cole, Sam Ted. *Life story, or Biographical sketches*. Edited by Kate Cob et al., Rout and Paul, 1983. Boll Series 75. Vol. 7 of *The cool works of Sam Ted Cole*.

———. *Remake of Life story*. 1995.

mla

15-7-43

Zar, Zoë C., and Adam D. Lau. “Algebra”. *Theory*, vol. 12, 2009, pp. 423–91. *arXiv*, arxiv.org/abs/math/9901.4711v13.

The style `mla` makes a few text transformation, e.g., shortening URLs or turning “University Press” into “UP”. These can be prevented by using `mla-strict` instead, Otherwise the two styles are identical. The style `mla7` implements an earlier version of the style guide, but right now it is not working correctly (maybe it does again by the time you have this book in your hands).

biblatex-oxref *Alex Ball* Implementations of the *2014 New Hart’s Rules* and the *2002 Oxford Guide to Style*.

15.7.6 Implementations of university and institution styles

The set of bundles in this category available on CTAN is certainly not representative: many more are likely to be available directly from institution websites or from your friendly fellow student. The styles normally implement a rather inflexible layout

without many options, often handle only a subset of all entry types, and sometimes support only a subset of the citation command's syntax. For example, some numeric styles in the current section do not properly handle page numbers in the optional argument, making it impossible to distinguish them from an entry reference.

However, they are less complex than style guide implementations, and so adapting them is usually possible. Typically, they load one of the generic styles and modify it, so they can also serve as examples on how to write a new style. Before using such a style, it is a good idea to check how old it is, if it is still maintained, and whether the rules it implements are actually still promoted by the institution.

15.7.8 Styles that extend the data model

The following bundles provide styles that add new field or entry types. To give at least a small impression of their purpose, the samples show special entries, often based on examples found in the documentation of the bundle.

biblatex-bookinother Maïeul Rouquette The style adds new entry types and fields for books edited in other types, such as `bookinarticle`. It offers only a `bib` style that is based on the standard `verbose` and should be used together with a `verbose` or `author-title` citation style.

Citation system: —

Bib style: bookinother

Style sample:

See Van Deun¹ and Cole²

Cole, Sam Ted. *The cool works of Sam Ted Cole*. Vol. 7.2: *Life story, or Biographical sketches*. Ed. by Kate Cob, Jon Eng, and W. Jack Bate. Boll Series 75. London: Rout and Paul, 1983.

Mémoire sur le saint apôtre Barnabé. Ed. by Peter Van Deun. In: Van Deun, Peter. “Un mémoire anonyme sur saint Barnabé (BHG 226e). Édition et traduction”. In: *Analecta Bollandiana* 108 (1990), pp. 326–335.

bookinother

¹*Mémoire sur le saint apôtre Barnabé*. Ed. by Peter Van Deun. In: Peter Van Deun. “Un mémoire anonyme sur saint Barnabé (BHG 226e). Édition et traduction”. In: *Analecta Bollandiana* 108 (1990), pp. 326–335.

²Sam Ted Cole. *The cool works of Sam Ted Cole*. Vol. 7.2: *Life story, or Biographical sketches*. Ed. by Kate Cob, Jon Eng, and W. Jack Bate. Boll Series 75. London: Rout and Paul, 1983.

15-7-119

bibtex-claves *Maïeul Rouquette* A special style for antic and medieval literature to handle many different texts published with the same title, or the same text published with different titles. It offers only a bib style: the example combines it with an author-title citation style.

Citation system: —

Bib style: `claves`

Style sample:

claves

See Bonnet (*Acta Barnabae*).

Acta Barnabae (BHG 225; CANT 285). In: *Acta Apostolorum Apocrypha*. Ed. by Maximilien Bonnet. Vol. 2.2. Leipzig: Hermann Mendelssohn, 1903, pp. 292–302.

15-7-120

bibtex-cv *Daniel E. Shub* The package implements entry types useful for an (American) academic curriculum vitae. It requires a special loading; check the documentation for details.

Citation system: — *Style:* `bibtex-cv`

Style sample:

cv

2010–2019 (£1,000,000, completed, CI): A Different Funding Agency, Fellowship (abc-def-123). *A Different Grant Title*.

By Smith, Alice and Bob Jones (Jan. 1, 2019). “An Internal Talk Abstract.” In: *Journal of Talk Abstracts*. [Talk presented by Alice Smith and Bob Jones].

15-7-121

bibtex-manuscripts-philology *Maïeul Rouquette* The style adds a new entry type `manuscript` to manage manuscripts in classical philology. It offers only a bibliography style that is based on `verbose`. The sample shows an example manuscript, the used citation style is `verbose`, and the citation command is `\textcite`.

Citation system: —

Bib styles: `manuscripts`, `manuscripts-noautosorthand`

Style samples:

CHAPTER 16

Managing Citations

16.1 Introduction	469
16.2 The number-only system	473
16.3 The author-date system	487
16.4 The author-number system.	502
16.5 The author-title system	507
16.6 The verbose system.	537
16.7 biblatex — One ring to rule them all	541
16.8 Multiple bibliographies in one document	569

16.1 Introduction

Citations are cross-references to bibliographical information outside the current document, such as to publications containing further information on a subject and source information about used quotations. It is certainly not necessary to back everything by a reference, but background information for controversial statements, acknowledgments of other work, and source information for used material should always be given.

The previous chapter showed numerous ways to compile bibliographies and reference lists. They can be prepared manually, if necessary, but usually they are automatically generated from a database containing bibliographic information. This chapter now introduces the many presentation forms of bibliographical sources, and it reviews different traditions regarding how such sources are referred to in a document.

We start the chapter with a short introduction to the major citation schemes in common use. Armed with this knowledge we then plunge into a detailed discussion of how \LaTeX supports the different citation schemes. At the time we wrote the first edition of this book, \LaTeX basically supported only the “number-only” system. Nearly three decades later, the situation has changed radically. Today, all major citation schemes are well supported by extension packages.

We end this chapter by discussing packages that can deal with multiple bibliographies in one document. This is not difficult if the reference lists are prepared manually or if `biblatex` together with `biber` is used, but it poses some challenges if you want to interact with `BibTeX`, as well.

16.1.1 Bibliographical reference schemes

There are five common methods of referring to sources: the “number-only”, “author-date” (or “author-year”), “author-number”, “author-title”, and “verbose” systems. The last two of these are often used in books on humanities and jurisdiction; the second appears mainly in science and social science works. The other two are less often used, although the first is quite common within the \LaTeX world, because it has been actively promoted by Leslie Lamport and originally was the only form of citation supported by \LaTeX . Outside the \LaTeX world, a variation of it, called “numeric by first citation”, is quite popular as well.

The number-only system

In the number-only system, publications are sequentially numbered in the bibliography. Citations in the text refer to these numbers, which are usually surrounded by brackets or parentheses. Sometimes raised numbers are used instead.

One argument against this system — put forward, for example, in *The Chicago Manual of Style* [40] — is that it raises the costs of publication, because a late addition or deletion of a reference may require renumbering and consequently costly (and error-prone) changes to many pages throughout the manuscript. With automatic cross-referencing facilities as provided by \LaTeX , this argument no longer holds true. In fact, the number-only system is the default system provided with \LaTeX .

In a slight variation, known as “alpha” style, citations comprise the author’s name and the year of the publication. Thus, the bibliographic label and the citation may look like “[Knu86]”. This is still fairly compact compared with an author-date or author-title style and has the advantage that one can often deduce the reference from the context.

Numerical by first citation

A fairly popular form of the number-only system numbers the publications sequentially by their first citation in the text (and presents them in that order in the bibliography). This is fairly easy to provide with either standard \LaTeX or `biblatex`. However, in that case it is important to avoid that references in the table of contents mess up the expected order; see Section 16.2.3 for advice on this.

The author-date system

In the author-date system (often referred to as the Harvard system after one of its better known typographical variants), references to sources are also given directly in the text. They show the author’s name (or names) and the year of the publication. The full citation is given in a list of references or a bibliography. If the author published more than one work in a given year, that year is suffixed with lowercase letters (e.g., 2001a, 2001b).

There have been many attempts over the years to provide author-date citation support for \LaTeX . With the `natbib` package (discussed in Section 16.3.2), the `jurabib` package (discussed in Section 16.5.1) and the `biblatex` package (discussed in Section 16.7 and 16.3.3), there are now three very flexible and general solutions available.

It should be possible for a reader to look up a cited reference in the bibliography lists. In all citation schemes that use author or editor names, the bibliography list therefore should normally be sorted alphabetically by these names. This can require special care if some of the names contain accented chars or are written in a non-Latin script; see Section 15.3.3 for some advice. The sorting should follow the rules of the main language of the document. This is easy to achieve with `biblatex`, because `biber` contains the necessary Unicode libraries, but with `BiBTeX` it can be necessary to add sort keys to some entries to guide the sorting.

Care must also be taken to get unique citation “labels”, which allow identifying the reference without ambiguity. For example, a work by three or more authors is usually referred to by using the name of the first author followed by *et al.* Especially with the author-date system, this may lead to ambiguous citations if different groups of authors with the same main author published in the same year. This problem can be seen in the following example:

 Watch out
for ambiguous
citations

```
\usepackage{chicago} \bibliographystyle{chicago}
Entries with multiple authors can be problematical, e.g., \shortcite{TLC94},
\shortcite{LGC97} and \shortcite{test97} or worse \shortcite{TLC94,LGC97,test97}.

\bibliography{tlc,tlc-ex}
```

Entries with multiple authors can be problematical, e.g., (Goossens et al. 1994), (Goossens et al. 1997) and (Goossens et al. 1997) or worse (Goossens et al. 1994; Goossens et al. 1997; Goossens et al. 1997).

Goossens, M., B. User, J. Doe, et al. (1997). Ambiguous citations. Submitted to the IBM J. Res. Dev.

16-1-1

In the above example the bibliography is produced from the sample `BiBTeX` databases `tlc.bib` and `tlc-ex.bib` that we introduced in the previous chapter in Figure 15.1 on pages 382–383 and Figure 15.2 on page 391. Those databases are also used in most examples throughout this chapter. Above we applied the `BiBTeX` style `chicago` and its accompanying support package to it, a style that aims to implement a bibliography and reference layout as suggested by *The Chicago Manual of Style* [40].

One way to resolve such ambiguous citations is to use more or all author names in such a case, although that approach can lead to lengthy citations and is not feasible if the number of identical authors exceeds a certain limit. Another solution is to

append a, b, and so on, to the year, even though the citations are actually for different author groups. This strategy is, for example, advocated in [28]. If the bibliography is compiled manually, as outlined in Section 15.1, this result can be easily achieved.

When using `BIBTEX`, you have to use a `BIBTEX` style file that recognizes these cases and provides the right data automatically. For example, the style `chicago` cannot be used in this case, but all `BIBTEX` styles produced with `custom-bib` (see Section 15.7.2) offer this feature:

Entries with multiple authors might be problematical, e.g., Goossens et al. [1997a] and Goossens et al. [1997b] or even Goossens et al. [1997a,b]. But then they might not.

References

M. Goossens, S. Rahtz, and F. Mittelbach. *The L^AT_EX Graphics Companion: Illustrating Documents with T_EX and PostScript*. Tools and Techniques for Computer Typesetting. Addison-Wesley Longman, Reading, MA, USA, 1997a. ISBN 0-201-85469-4.

M. Goossens, B. User, J. Doe, et al. Ambiguous citations. Submitted to the IBM J. Res. Dev., 1997b.

```
\usepackage{natbib}
\bibliographystyle
{abbrvnat}
```

Entries with multiple authors might be problematical, e.g., `\cite{LGC97}` and `\cite{test97}` or even `\cite{LGC97,test97}`. But then they might not.

```
\bibliography{tlc,tlc-ex}
```

16-1-2

When using `biblatex` with `biber`, the citations are almost¹ always unambiguous from the start. The package adds, if needed, initials, given names, more authors, or an extra year marker. The behavior can be fine-tuned with the options `uniquelist`, `uniquename`, `maxnames`, `maxcitenames`, and `maxbibnames`. The settings in the next example force short author lists and automatically append letters to the year if needed. Details on the customization possibilities of the `biblatex` package are covered in Section 16.7 starting on page 541.

```
\usepackage[style=authoryear,
  uniquelist=false,maxnames=1]{biblatex}
\addbibresource{tlc.bib}
\addbibresource{tlc-ex.bib}
```

Entries with multiple authors might be problematical, e.g., Goossens et al. 1997b and Goossens et al. 1997a or even Goossens et al. 1997b; Goossens et al. 1997a. But then they might not.

Entries with multiple authors might be problematical, e.g., `\cite{LGC97}` and `\cite{test97}` or even `\cite{LGC97,test97}`. But then they might not.

16-1-3

With just `\usepackage[style=authoryear]{biblatex}` it would have produced the far lengthier result instead:

Entries with multiple authors might be problematical, e.g., Goossens, Rahtz, and Mittelbach 1997 and Goossens, User, Doe, et al. 1997 or even Goossens, Rahtz, and Mittelbach 1997; Goossens, User, Doe, et al. 1997. But then they might not.

16-1-4

¹It can fail if two references have identical authors *and* title and an author-title style is used.

In the author-number system, the references to the sources are given in the form of the author's name (or names) followed by a number, usually in parentheses or brackets, indicating which publication of the author is cited. In the corresponding bibliography all publications are numbered on a per-author (or author group) basis. In the \LaTeX world this system is fairly uncommon because it is difficult to produce manually. As far as we know, there is currently no \BibTeX support available for it, but for biblatex suitable styles exist in the biblatex-ext bundle; see Section 16.4.2 on page 506.

The author-number system

In the author-title system, the reference to a source is also given directly in the text, either inline or as a footnote, this time using the author or editor names and the title often in the form “Hart, *Hart's Rules*, p. 52”. In the context of the publication, if abbreviations for the title are established, the form “Goossens et al., *LGC*” may appear as an alternative. Many variations exist. For instance, the first time a work is cited it might be presented with a long title; later references might then use a shorter form — citing only the author's name and a short title or the year. In the case of repeated citations to the same work in direct succession, you might find *Ibid.* instead of a repeated reference.

The author-title system

An implementation of the author-title system, based on a \BibTeX workflow, is provided by the jurabib [15] package discussed Section 16.5.1 on page 507 followed by an overview of the possibilities offered by biblatex in Section 16.5.2 on page 534.

Finally, in the verbose system a full reference is given the first time a work is cited — usually done in a footnote. Later references then use a shorter version. If this style is used, a list of references or a bibliography that contains all cited works in a single place is not strictly necessary and can be omitted. Typically verbose systems use some combination of the author's name and the title for the shorter reference and can be viewed as a variant of the author-title system. It is therefore not surprising that the two packages that support the author-title system (i.e., biblatex and jurabib) handle that format too. The bibentry package also offers some partial support.

The verbose system

Table 16.1 on the following page shows a broad comparison of the features of major citation packages. A check mark means that the package has sufficient support, if in parentheses there is only partial support. In general, biblatex has the most comprehensive coverage.

Comparison of bibliography packages

16.2 The number-only system

As mentioned earlier in this chapter, the number-only system is the default citation method directly supported by standard \LaTeX . That is, without loading any additional packages, it is the only method supported by the provided markup commands. We start this section by describing those commands. We then cover the cite package that offers enhanced sorting and formatting of the citation numbers. This is followed by a brief look at the notoccite package that solves a small problem with citations in headings and captions. Then we explain how natbib handles number-only citations and at last present biblatex's approach to the number-only system.

Table 16.1: Comparison of different bibliographical support packages

16.2.1 Standard L^AT_EX — Reference by number

Bibliographic citations inside the text of a L^AT_EX document are produced with the command `\cite`.

```
\cite[post-note]{key1,key2,...}
```

The `\cite` command associates each key in the list in its mandatory argument with the argument of a `\bibitem` command from the `thebibliography` environment described in Section 15.1 to produce the citation reference. As with other L^AT_EX identifiers, these keys are case-sensitive.

The citation numbers generated are defined by the order in which the keys appear on the `\bibitem` commands inside the `thebibliography` environment or, if an optional argument is used with `\bibitem`, by the data provided in that argument.

The optional parameter *post-note* is an additional note, which is printed together with the text generated by the `\cite` command as shown in the following example. For comparison we have used an unbreakable space (~) in the first citation and a small space (\,) in the second. Of course, such typographical details should be handled uniformly throughout a publication.

The exact format of the citation in the text depends on the chosen bibliographic style and possible customizations made in the document class or in the preamble.

Color support for L^AT_EX is described in [2, chap. 9] and the `hyperref` package in [1, pp. 35–67].

```
\bibliographystyle{plain}
```

Color support for L^AT_EX is described in `\cite[chap.~9]{LGC97}` and the `\texttt{hyperref}` package in `\cite[pp.\,35--67]{LWC99}`.

16-2-1

To save space, examples in this chapter based on B^BT_EX often omit the bibliography list. They are generated by placing `\bibliography{t1c}` at the end of the example document when automatically generating the example output for the book. Thus, you should read examples such as 16-2-1 as follows: the result is produced by generating the bibliography with B^BT_EX, applying the style `plain` (shown), and using the database `t1c.bib` (not shown; see Figure 15.1 on pages 382–383). Thus, the actual document that produced the example contained `\newpage\bibliography{t1c}` at the end, ending up on a page of its own. Examples using `biblatex` and `biber` do not need a bibliography list to show citations, so nothing is omitted in their source display.

 A note
on B^BT_EX-based
examples in this
chapter

```
\nocite{key1,key2,...}
```

In conjunction with B^BT_EX and `biblatex`, you can use the `\nocite` variant of the `\cite` command. Its sole purpose is to write the keys in its argument into the `.aux` or the `.bcf` file so that the associated bibliography information appears in the bibliography even if the publication is otherwise not cited (thus, this is useful only if you do not prepare the reference list manually). It can be used as often as necessary. As a special case, `\nocite{*}` includes all entries of the chosen B^BT_EX databases in the list of references.

Customizing citation references and the bibliography in standard L^AT_EX

Unfortunately, standard L^AT_EX is not equipped with an easily customizable interface through which you can adjust the formatting of the citation references. Thus, even to just change the default brackets around the numbers into parentheses, we need to redefine the internal L^AT_EX command `\@cite`.

Even worse, the user-level `\cite` command uses an internal temporary switch (`@tempswa`) to indicate whether an optional argument was present. Thus, if we want to handle that optional argument, we need to evaluate the value of that switch. The `\@cite` command receives two arguments: the list of obtained references and the note (if present). In the following example we typeset `(#1` and, if `@tempswa` is true, follow it by a comma and `_#2`. This is then followed by the closing parenthesis. The `\nolinebreak[3]` ensures that a break after the comma is taken only reluctantly.

```
\bibliographystyle{plain} \usepackage{ifthen}
\makeatletter
\renewcommand\@cite[2]{({#1\ifthenelse
  {\boolean{@tempswa}}{, \nolinebreak[3] }#2}{})}
\makeatother
```

Color support for L^AT_EX is described in (2) and the `hyperref` package in (1, pp. 35–67).

Color support for L^AT_EX is described in `\cite{LGC97}` and the `\texttt{hyperref}` package in `\cite[pp.\,35--67]{LWC99}`.

16-2-2

The redefinition of `\@cite` for purposes like the above can be avoided by loading the `cite` package; see Section 16.2.2.

For the `thebibliography` environment, which holds the list of the actual references, the situation is unfortunately not much better — the default implementation in the standard document classes offers few customization possibilities. To modify the layout of the labels in front of each publication (e.g., to omit the brackets), you have to change the internal L^AT_EX command `\@biblabel`.

\makeatletter
\renewcommand\@biblabel[1]{#1.}
\makeatother
\nocite{Knuth-CT-a,Knuth:TB10-1-31}
\bibliography{t1c}
```

16-2-3

Packages that implement a variation of the author-date system (e.g., the `apalike`, `chicago`, or `natbib` package), typically unconditionally redefine `\@biblabel` to simply swallow its argument and typeset nothing. After all, such a bibliography is used by looking up the author name, so a label is unnecessary. The `natbib` package is somewhat more careful: if it detects that `\@biblabel` was changed, then it honors the redefinition.

As mentioned earlier, different blocks of information, such as the authors or the title, are separated inside one `\bibitem` in the bibliography by `\newblock` commands, which are also automatically inserted by most B^BT_EX styles. Normally,

bibliographic entries are typeset together in one paragraph. If, however, you want your bibliography to be “open”, with each block starting on a new line with succeeding lines inside a block indented by a length `\bibindent` (default 1.5em), then the class option `openbib` should be specified. This option is supported by all standard classes. The result is shown in the next example; we also redefine `\@biblabel` to produce raised labels.

16-2-4

Customizing citation references and the bibliography with biblatex

With `biblatex` such customizations do not require the redefinitions of internal commands because the package provides various powerful interfaces to adapt the output. These are described in more detail in Section 16.7, but for comparison we repeat the adaptations made for standard L^AT_EX.

The next example uses `\DeclareCiteCommand` provided by `biblatex` to redefine the citation command. The `\mkbibparens` command used in the optional argument replaces `\mkbibbrackets` used in the default definition and adds parentheses instead of brackets around the citation. Note that with `biblatex` the page numbers are given as a simple range in the optional argument of the `\cite` command. `biblatex` converts the hyphen to an en-dash and adds the “pp.” automatically.

```
\usepackage[style=numeric]{biblatex}
\addbibresource{tlc.bib}
\DeclareCiteCommand{\cite}{\mkbibparens}
{\usebibmacro{prenote}}
{\usebibmacro{citeindex}\usebibmacro{cite}}
{\multicitedelim}
{\usebibmacro{postnote}}
```

Color support for L^AT_EX is described in (2) and the `hyperref` package in (1, pp. 35–67).

See also (3, 4).

Color support for L^AT_EX is described in `\cite{LGC97}` and the `\texttt{hyperref}` package in `\cite[35-67]{LWC99}`.

See also `\cite{MR-PQ, Southall}`.

16-2-5

Such redefinitions of citation commands are always possible, but `biblatex` styles may also offer additional commands and options to ease such customizations. The next example demonstrates this with the command `\DeclareOuterCiteDelims`

offered by the style `ext-numeric` — a generic, easy-to-customize style from the `biblatex-ext` package — to switch to parentheses like in Example 16-2-5.

Color support for \LaTeX is described in (2) and the `hyperref` package in (1, pp. 35–67).

See also (3, 4).

```
\usepackage[style=ext-numeric]{biblatex}
\addbibresource{tlc.bib}
\DeclareOuterCiteDelims{cite}{\bibopenparen}{\bibcloseparen}
Color support for \LaTeX{} is described in \cite{LGC97} and
the \texttt{hyperref} package in \cite[35-67]{LWC99}. \par
See also \cite{MR-PQ, Southall}.
```

16-2-6

To change the label in the bibliography to use only a period as in Example 16-2-3 you can use the `\DeclareFieldFormat` command. The example uses the style `trad-abbrev` from the `biblatex-trad` bundle — a reimplementaion of the standard `abbrev` style.

References

1. D. E. Knuth. *The $T_{\text{E}}X$ book*, volume A of *Computers and Typesetting*. Addison-Wesley, Reading, MA, USA, 1986, pages ix + 483. ISBN: 0-201-13447-0.

```
\usepackage[style=trad-abbrev]{biblatex}
\addbibresource{tlc.bib}
\DeclareFieldFormat{labelnumberwidth}{\#1\addodot}
\nocite{Knuth-CT-a}
\printbibliography
```

16-2-7

The class option `openbib` used in Example 16-2-4 is also honored by `biblatex`; in addition, it offers a package option `block=par` to the same effect.

16.2.2 cite — Enhanced references by number

One shortcoming that becomes readily apparent when you use \LaTeX 's default method of citing publications is the fact that it faithfully keeps the order of citations as given in the *key-list* argument of the `\cite` command. The following example therefore shows a very strangely ordered list of numbers (the unresolved reference was added deliberately):

Good information about $T_{\text{E}}X$ and \LaTeX can be found in [2, 1, 3, ?, 4].

```
\bibliographystyle{plain}
Good information about \TeX{} and \LaTeX{} can be found in
\cite{LGC97,LWC99,Knuth-CT-a,Knuth:ct-b,Knuth:TB10-1-31}.
```

16-2-8

For bibliographies produced with $\text{Bib}\TeX$ the situation can be easily improved by simply loading the `cite` package (by Donald Arseneau), as in the following example:

Good information about $T_{\text{E}}X$ and \LaTeX can be found in [?, 1–4].

```
\usepackage{cite} \bibliographystyle{plain}
Good information about \TeX{} and \LaTeX{} can be found in
\cite{LGC97,LWC99,Knuth-CT-a,Knuth:ct-b,Knuth:TB10-1-31}.
```

16-2-9

By default, the `cite` package sorts citation numbers into ascending order, representing three or more consecutive numbers as a number range. Any nonnumeric label is moved to the front (in the above example the “?” generated by the unresolved reference). If sorting is not desired, you can globally prevent it by loading the package

with the option `nosort`. Suppressing range compression can be achieved by using the option `nocompress`.

To customize the typeset reference the `cite` package offers a number of commands. For example, `\citeleft` and `\citeright` determine the material placed on the left and right sides of the citation string, respectively. These commands can be used to typeset parentheses instead of brackets as seen in the following example, which should be compared to Example 16-2-2 on page 476. We can also redefine `\citimid`, the separation between citation and optional note, to produce a semicolon and a space.

Customizing the citation layout

Color support for L^AT_EX is described in (2) and the `hyperref` package in (1; pp. 35–67).

16-2-10

```
\usepackage{cite} \bibliographystyle{plain}
\renewcommand\citeleft{() \renewcommand\citeright{)}
\renewcommand\citimid{; \nolinebreak[3] }
```

Color support for L^AT_EX is described in `\cite{LGC97}` and the `\texttt{hyperref}` package in `\cite[pp.\,35--67]{LWC99}`.

Another important aspect of citation management is controlling the behavior near the end of a line. Consider the string “see [2–3,7,13]”. Besides not allowing any kind of line break within this string, one could allow breaking after the “see”, after the commas, or after the en-dash in a range.

Customizing breaks within citations

By default, the `cite` package discourages line breaks before the citation with `\nolinebreak[3]`, discourages line breaks after a comma separating the optional note with `\nolinebreak[2]`, and very strongly discourages line breaks after en-dashes in a range and after commas separating individual citation numbers. You can control the last three cases by redefining `\citimid`, `\citedash`, and `\citepunct`. For example, to prevent breaks after the en-dashes while allowing breaks after commas without much penalty, you could specify

```
\renewcommand\citedash{\mbox{--}\nolinebreak}
\renewcommand\citimid{,\nolinebreak[1] }
\renewcommand\citepunct{,\nolinebreak[1]\hspace{.13em plus .1em minus .1em}}
```

There are several interesting points to note here. All three definitions are responsible not only for controlling any line breaks but also for adding the necessary punctuation: a dash for the range, a comma and a full blank before the optional note, or a comma and a tiny space between individual citations. For instance, if you want no space at all between citations, you can redefine `\citepunct` to contain only a comma. The other important and probably surprising aspect is the `\mbox` surrounding the en dash. This box is absolutely necessary if you want to control L^AT_EX's ability to break at this point. T_EX automatically adds a breakpoint after an explicit hyphen or dash, so without hiding it in a box, the `\nolinebreak` command would never have any effect — the internally added breakpoint would still allow a line break at this point. Finally, the `\hspace` command allows for some stretching or shrinking; if you prefer a fixed space instead, remove the plus and minus components.

A penalty of `\nolinebreak[3]` that is added before a citation is hardwired in the code. It is, however, inserted only if you have not explicitly specified a penalty

in your document. For instance, “`see~\cite{..}`” is honored, and no break happens between “see” and the citation.

Customizing citation numbers

One more customization command, `\citeform`, allows you to manipulate the individual reference numbers. By default, it does nothing, so the labels are typeset unchanged. In the following example we colored them. Other kinds of manipulation are possible, too (e.g., adding parentheses as in Example 16-2-12 below).

Color support for L^AT_EX is described in [2] and the `hyperref` package in [1, pp. 35–67].

```
\usepackage{cite,color} \bibliographystyle{plain}
\renewcommand\citeform[1]{\textcolor{blue}{#1}}

Color support for \LaTeX{} is described in \cite{LGC97} and
the \texttt{hyperref} package in \cite[pp.\,35--67]{LWC99}.
```

16-2-11

```
\citen{key1,key2,...}
```

The package offers an additional command, `\citen` (its aliases are `\citenum` and `\citeonline`), that can be used to get a list of numbers without the surrounding `\citeleft` and `\citeright` (e.g., the default brackets). Other formatting is still done. In the next example we surround individual references to citations with parentheses to prove that point, something that admittedly looks a little strange when used together with the default bracketing of the whole citation. Also note how undefined references (i.e., `test97`) are handled by that command: you get a bold question mark on its own.

```
\usepackage[nospace]{cite} \bibliographystyle{plain}
\renewcommand\citeform[1]{(#1)}

?,(1),(2),(4) but [(3), §5] \citen{LGC97,LWC99,test97,vLeunen:92} but \cite[\S5]{Knuth-CT-a}
```

16-2-12

Package options

The package offers a number of options to handle standard configuration requests or to influence the package behavior in other ways. Some of them have already been discussed, but here is the full list:

adjust/noadjust Enables (default) or disables “smart” handling of space before a `\cite` or `\citen` command. By default, spaces before such commands are normalized to an interword space. If you write `see\cite{..}`, a space is inserted automatically.

compress/nocompress Enables (default) or disables compression of consecutive numbers into ranges.

nobreak Remove any default breakpoint from the citation reference so that it always appears on a single line, regardless of its length, preventing output such as in Example 16-2-8 on page 478. May result in bad line breaks in which case one needs to manually add line-break possibilities with `\linebreak`.

nospace Eliminates the spaces after commas in the list of numbers, but retains the space after the comma separating the optional note. The result of this option is shown in Example 16-2-12 on the preceding page. It is not the opposite of the **space** option!

space A full interword space is used after commas, and breaking at this point is not actively discouraged. The default (option not specified) is to use a small space and to discourage, but allow, breaking.

sort/nosort Enables (default) or prevents sorting of the numbers.

superscript or **super** Typeset citation references as superscript numbers (like footnotes). When this option is selected, there are a number of further options that can be useful. See the discussions below.

ref Support option when using superscript numbers as citation references. Typesets `Ref :` in certain situations.

move/nomove Support option when using superscript numbers as citation references. Moves (default) or does not move punctuation following a reference in front of it.

biblabel Alter the label produced by `\bibitem` to produce the same output as the reference in the text. Mainly meant to get superscript labels when references use superscripts.

verbose By default, `cite` warns only once per reference for undefined citations. When this option is specified, the warning is repeated each time an undefined reference is cited.

Citations with superscript numbers

The `cite` package can also display citation references as superscript numbers if the package is loaded with the option `superscript` (or `super`). If the `\cite` command is used with an optional argument, then the whole list of citations is typeset as though the `cite` package was loaded without the `superscript` option.

With the `superscript` or `super` option in effect, the customization commands `\citeleft`, `\citeright`, and `\citimid` affect only citations with an optional argument, while `\citedash`, `\citepunct`, and `\citeform` affect all citations. For details of their use, see the discussion on pages 479–480.

```
\usepackage[superscript]{cite}
\bibliographystyle{plain}
\usepackage{color}
\renewcommand\citeform[1]{\textcolor{blue}{#1}}
\renewcommand\citeleft{() \renewcommand\citeright{}}
```

Good information about \TeX and \LaTeX can be found in^{2,1-4}

For `\hyperref` see (1, pp. 35–67).

Good information about `\TeX` and `\LaTeX` can be found in `\cite{LGC97,LWC99,Knuth-CT-a,Knuth:ct-b,Knuth:TB10-1-31}`. For `\texttt{\hyperref}` see `\cite{pp.\,35--67}{LWC99}`.

You can normally use the same input convention, regardless of whether the `superscript` option is used. In particular, a space before the citation command is ignored if the citations are raised. This means that you can add this option without having to adjust your document sources, provided your writing style does not use the numerical citation as part of the sentence structure, as we did in the previous example — producing a rather questionable result.

However, raised citations numbers can easily be confused with footnote markers, so using both together in a document is not recommended, unless you switch to symbols or alphabetic letters for footnote markers.

Good information¹ can be found in.^{1,2}

¹Confusing footnote!

```
\usepackage[superscript]{cite}
\bibliographystyle{plain}
Good information\footnote{Confusing footnote!}
can be found in \cite{LGC97,LWC99}.
```

16-2-14

If superscript numbers are used for citation labels, special care is needed when punctuation characters surround the citation. By default, the `cite` package automatically moves a punctuation character following a citation in front of the superscript. Punctuation characters that migrate in this way are stored in the command `\CiteMoveChars`, with “.,;:” being the default (! and ? are not included, but can be added). A problem that can result from this process is the doubling of periods. This case is usually detected by the package, and one punctuation character is suppressed; see the second citation in the next example.

... book;² see also Goossens et al.¹

```
\usepackage[superscript]{cite}
\bibliographystyle{plain}
\ldots\ book~\cite{Knuth-CT-a}; see also
Goossens et al.\cite{LGC97}.
```

16-2-15

Unfortunately, with capitalized abbreviations or the use of `\@` after a period, the suppression of double periods fails. Possible workarounds are shown in the next example. Note, however, that the solution with `U.S.A\@.` works only together with the `cite` package, but it gives the wrong spacing if the citation is not raised (you are effectively claiming that the sentence ends after the abbreviation)!

et al.¹
U.S.A..²

et al.¹
U.S.A..²

```
\usepackage[super]{cite}
\bibliographystyle{plain}
et al.\@ \cite{LGC97}. \hfil et al.\ \cite{LGC97}.
U.S.A. \cite{unknown}. \hfil U.S.A\@. \cite{unknown}.
```

16-2-16

There is yet another pitfall that you may encounter: the final punctuation character does not migrate inside a preceding quotation — a style, for example, advocated

by *The Chicago Manual of Style* [40]. In this case you may have to rewrite part of your source text accordingly.

16-2-17

For details see “The T_EXbook”.¹ But wanted is “The T_EXbook.”¹

```
\usepackage[super]{cite} \bibliographystyle{plain}
For details see ‘‘The \TeX book’’ \cite{Knuth-CT-a}.
But wanted is ‘‘The \TeX book.’’ \cite{Knuth-CT-a}
```

Three more options related to raising the reference numbers exist. With the option `nomove` specified, punctuation characters are not migrated before the superscript citation. With the option `ref` specified, citations with an optional argument have the word “Ref.” prepended. This is internally implemented by changing `\citeleft`, so if you want a different string or want to change from brackets to, say, parentheses, you have to redefine the customization commands instead of using this option.

16-2-18

Color support is described in “LGC”² and the `hyperref` package in “LWC” [Ref. 1, pp. 35–67].

```
\usepackage[super,ref]{cite}
\bibliographystyle{plain}
Color support is described in ‘‘LGC’’ \cite{LGC97}
and the \texttt{hyperref} package in ‘‘LWC’’
\cite[pp.\,35--67]{LWC99}.
```

Finally, the `biblabeled` option raises the labels in the bibliography. By default, their default layout is retained regardless of whether you use the option `superscript` or its alias `super`.

16.2.3 notoccite — Solving a problem with unsorted citations

If you want the publications in the bibliography to appear in exactly the order in which they are cited in the document, then you should use unsorted citation styles (e.g., the B_T_EX style `unsrt`). This approach does not work, however, if citations are present inside headings or float captions. In that case, these citations also appear in the table of contents or list of figures, and so on. As a result they are moved to the beginning of the bibliography even though they appear much later in the text.

You can avoid this problem by providing an optional argument to `\caption`, `\section`, or similar commands not containing the citation so that no citations are written into such lists. If you have to use citations in these places, then a “manual” solution is to first delete any auxiliary files left over from previous L^AT_EX runs, then run L^AT_EX once, and then run B_T_EX. In that case B_T_EX picks up only citations from the main document. Clearly, this approach is prone to error, and you may find that your citation order got mangled after all when you finally see your article in print.

Donald Arseneau developed the small package `notoccite` to take care of this problem by redefining the internal command `\@starttoc` in such a way that citations do not generate `\citation` commands for B_T_EX within the table of contents and similar lists. Simply loading that package takes care of the problem in all cases — provided you have not used some other package that redefines `\@starttoc` (for example, `notoccite` cannot be combined with the AMS document classes).

 `notoccite`
not needed with
`biblatex`; see
Section 16.2.5

16.2.4 natbib's approach to number-only references

Although originally designed to support the author-date system, natbib is also capable of producing number-only references. The natbib package *automatically* switches to numerical mode if any one of the `\bibitem` entries fails to conform to the possible author-date formats. In such cases the commands `\cite` and `\citep` are usable, but `\citet` issues a warning about the missing author and prints a bold “author?”:

[1], [1], (author?) [1]

References

- [1] Donald E. Knuth. Typesetting Concrete Mathematics. *TUGboat*, 10(1):31–36, April 1989.

```
\usepackage{natbib}
\bibliographystyle{plain}

\cite{Knuth:TB10-1-31},
\citep{Knuth:TB10-1-31},
\citet{Knuth:TB10-1-31}
\bibliography{t1c}
```

16-2-19

To force the numeric mode even if the bibliography style would allow an author-date system, load natbib with the `numbers` option or choose the citation style with `\setcitestyle{numbers}`.

(1), (1), Knuth (1)

References

- [1] Donald E. Knuth. Typesetting Concrete Mathematics. *TUGboat*, 10(1):31–36, April 1989. ISSN 0896-3207.

```
\usepackage{natbib} \setcitestyle{numbers}
\bibliographystyle{plainnat}

\cite{Knuth:TB10-1-31},
\citep{Knuth:TB10-1-31},
\citet{Knuth:TB10-1-31}
\bibliography{t1c}
```

16-2-20

This creates a variant of the author-number system — details and examples are given in Section 16.4.1 on page 503 where we discuss this system.

16.2.5 biblatex's approach to number-only references

We describe the biblatex package in more detail in Section 16.7 but give also for every citation system an overview of the main points of its implementation.

The biblatex package ships with three numeric styles, `numeric`, `numeric-comp`, and `numeric-verb`. The “alpha” citation style is supported with `alphabetic` and `alphabetic-verb` — the latter being more verbose. More styles are provided by external packages as shown in the overview of styles in Section 15.7.3. Those styles are loaded in the package options with the `style` key, but because the initial value of the `style` key is `numeric`, simply loading the biblatex package is enough to select a number-only citation system.

Compatibility with
natbib

Besides the `\cite` command, the biblatex package offers a large variety of other citation commands; as with natbib all commands have two optional arguments. The `\textcite` command gives an author-number citation — similar to the `\citet` command of natbib, while `\parencite` and `\cite1` are comparable to `\citep`. The package option `natbib` enables emulations of the natbib commands; this simplifies

¹The difference between both is apparent only in author-based citation systems.

converting existing documents but does not cover all syntax differences: recall from Example 16-2-5 that the pages in the optional argument of `biblatex`'s citation commands are given without a prefix and that the range uses a simple hyphen; thus, some syntax adaptations are needed.

The following example sets with the keys `maxnames` and `minnames` the length of the author list to demonstrate the difference between `\citet` and `\citet*`.

	<code>\usepackage[natbib,minnames=2,maxnames=2]{biblatex}</code>
	<code>\addbibresource{tlc.bib}</code>
Knuth [2]	<code>\textcite{Knuth:TB10-1-31}</code> <code>\\</code>
[see also 1, pp. 2–4]	<code>\parencite[see also][2-4]{LGC97}</code> <code>\\</code>
Goossens, Rahtz, et al. [1]	<code>\citet{LGC97}</code> <code>\\</code>
Goossens, Rahtz, and Mittelbach [1]	<code>\citet*{LGC97}</code> <code>\\</code>
[see 1, pp. 35–44]	<code>\citep[see][35-44]{LGC97}</code> <code>\\</code>
Goossens, Rahtz, et al.	<code>\citeauthor{LGC97}</code> <code>\\</code>
Goossens, Rahtz, and Mittelbach	<code>\citeauthor*{LGC97}</code>

16-2-21

Some starred citation commands are defined by both packages but behave differently. If the `natbib` emulation is enabled, the `biblatex` package redefines those commands to match the `natbib` behavior. Most importantly the `\citeauthor*` command shows with `natbib` and the `natbib` emulation *all* authors, while with `biblatex` it *truncates* the name list. If you want all authors for one citation, you can set the `maxnames` counter inside `\AtNextCite` as shown or define a citation command to this effect. The counter is automatically reset by `biblatex` afterwards.

 *natbib emulation*
changes starred
commands

	<code>\usepackage[minnames=2,maxnames=2]{biblatex}</code>
	<code>\addbibresource{tlc.bib}</code>
Goossens, Rahtz, et al.	<code>\citeauthor{LGC97}</code> <code>\\</code>
Goossens et al.	<code>\citeauthor*{LGC97}</code> <code>\\</code>
Goossens, Rahtz, and Mittelbach	<code>\AtNextCite{\setcounter{maxnames}{99}}%</code>
Goossens, Rahtz, et al.	<code>\citeauthor{LGC97}</code> <code>\\</code>
	<code>\citeauthor{LGC97}</code> <code>% maxnames automatically reset</code>

16-2-22

Donald Arseneau's `cite` package is incompatible with `biblatex`, which addresses citation sorting differently. The functionality of `notoccite` is built into `biblatex`: citations in the table of contents and similar lists are printed but otherwise ignored and so do not affect the numbering. However, in contrast to the incompatibility between `cite` and `biblatex`, there is no conflict if `notoccite` is loaded too — it is simply not necessary.

For the purpose of fully adapting the format of citation commands, `biblatex` offers the command `\DeclareCiteCommand` that we describe in Section 16.7.16, but various typical layouts can be achieved either with existing package options or by switching to another citation style. The option `sortcites` sorts list of citations as they are sorted in the bibliography and also suppresses duplicates. Compare the output of the next two examples:

	<code>\usepackage{biblatex}</code>
[2, 1, KpV]	<code>\cite{cicero,angenendt,kant:kpV}\\</code>
[2, KpV, 2, 1]	<code>\cite{cicero,kant:kpV,cicero,angenendt}</code>

16-2-23

In the previous example the reference to `cicero` appeared twice; now all references are sorted and duplicates are suppressed:

```
\usepackage[sortcites]{biblatex}
[1, 2, KpV] \cite{cicero,angenendt,kant:kpV}\
[1, 2, KpV] \cite{cicero,kant:kpV,cicero,angenendt}
```

16-2-24

Compressed and sorted citations can be produced, for example, by using a style such as `numeric-comp`. Note that unresolved citations are not marked with a question mark but show the citation key in bold. Redoing Example 16-2-9 from page 478 thus gives:

```
\usepackage[style=numeric-comp]{biblatex}
\addbibresource{tlc.bib}
Good information about TEX and LATEX can be found in [Knuth:ct-b, 1–4].
Good information about \TeX{} and \LaTeX{} can be found in
\cite{LGC97,LWC99,Knuth-CT-a,Knuth:ct-b,Knuth:TB10-1-31}.
```

16-2-25

How to use parentheses instead of brackets has already been demonstrated in Example 16-2-6 on page 478. We now extend this example and also change the punctuation before the *post-note* and the punctuation between two citations by redefining two standard `biblatex` commands:

```
\usepackage[style=ext-numeric-comp]{biblatex}
\addbibresource{tlc.bib} \DeclareOuterCiteDelims{cite}{(}{)}
\renewcommand\postnotedelim{\addsemicolon\addspace}
\renewcommand\multicitedelim{\addsemicolon\addspace}
Color support for LATEX is described in (2) and the hyperref
package in (1; pp. 35–67).
See also (3; 4).
Color support for \LaTeX{} is described in \cite{LGC97}
and the \texttt{hyperref} package in \cite[35-67]{LWC99}.
\par See also \cite{MR-PQ, Southall}.
```

16-2-26

Citations can be displayed as superscripts in selected bibliography styles (e.g., the numeric styles of `biblatex` and `biblatex-ext`) with the command `\supercite`. If the document uses `\autocite` as a citation command, the package option `autocite=superscript` switches to superscripts too. Citations typeset as superscripts ignore the *pre-note* and *post-note* arguments with a warning — you can use a normal `\cite` to get an unraised citation with notes. Below we repeat Example 16-2-13 on page 481 altered to use `biblatex` including the change to use parentheses, because that was also changed in the earlier example.

```
\usepackage[style=ext-numeric-comp,maxcitenames=1]{biblatex}
\addbibresource{tlc.bib} \DeclareOuterCiteDelims{cite}{(}{)}
Good information about TEX and LATEX can be found in Knuth:ct-b, 1–4. For
hyperref see (1, pp. 35–67).
in \supercite{LGC97,LWC99,Knuth-CT-a,Knuth:ct-b,%
Knuth:TB10-1-31}.
For \texttt{hyperref} see \cite[35-67]{LWC99}.
```

16-2-27

Similar to `\cite` in the `cite` package, `\autocite` tries to move punctuation before the citation if it is used with `autocite=superscript`. It does not suppress a double period created, for example, from an abbreviation. You have to rewrite your text in such cases.

```
\usepackage[maxcitenames=1,style=numeric-comp,
             autocite=superscript]{biblatex}
\addbibresource{tlc.bib}
```

16-2-28 See Knuth,² see also Goossens et al..¹

```
See \citeauthor{Knuth-CT-a}~\autocite{Knuth-CT-a},
\citeauthor[see also][]{LGC97}~\autocite{LGC97}.
```

Above, we retrieved the author names with `\citeauthor` and forced the use of “et al.” after the first author with the option `maxcitenames=1`.

In summary, the big difference between `cite` and `biblatex` with respect to superscript citations is that the latter expects you to use different commands for the citations in your document, i.e., `\supercite`, instead of getting an altered behavior of the standard `\cite` command. If this is not to your liking, you can copy the (quite short) definition of `\supercite` from `numeric.cbx` and use it to redefine `\cite`.

Finally, we show a short example for an “alpha” style that can be produced with, for example, the alphabetic style. In this style the label is built from the initials of some of the authors and a part of the year; additional authors are indicated by a plus symbol. In the following example we restrict the number of authors to two (the default is three) with `maxalphanames`:

The “alpha” style

```
\usepackage[style=alphabetic,minalphanames=2,
             maxalphanames=2]{biblatex}
```

Knuth [Knu86], Knuth [Knu89]

```
\addbibresource{tlc.bib}
```

Goossens, Rahtz, and Mittelbach [GR+97]

```
\textcite{Knuth-CT-a}, \textcite{Knuth:TB10-1-31} \\\
```

16-2-29

Goossens and Rahtz [GR99]

```
\textcite{LGC97} \\\ \textcite{LWC99}
```

With the command `\DeclareLabelalphaTemplate`, the template for the label can be redefined; in its argument various instructions for how to construct the label can be given. The following example creates short labels based only on the names. Note how the two Knuth citations are distinguished with additional letters.

```
\usepackage[style=alphabetic,minalphanames=2,
             maxalphanames=2]{biblatex}
```

```
\DeclareLabelalphaTemplate
```

```
{\labelelement{\field{varwidth}{labelname}}}
```

```
\addbibresource{tlc.bib}
```

Knuth [Ka], Knuth [Kb]

Goossens, Rahtz, and Mittelbach [GR+]

```
\textcite{Knuth-CT-a}, \textcite{Knuth:TB10-1-31} \\\
```

16-2-30

Goossens and Rahtz [GR]

```
\textcite{LGC97} \\\ \textcite{LWC99}
```

16.3 The author-date system

Depending on the structure of the sentence, the author-date system normally uses one of two different forms for references: if the author’s name appears naturally in the sentence, it is not repeated within the parentheses or brackets; otherwise, both

the author's name and the year of publication are used. This style poses an unsolvable problem when \LaTeX 's standard syntax is used, because only one command (`\cite`) is available.

Consequently, anyone developing support for the author-date system has had to extend the \LaTeX syntax for citing publications. The following example shows the two forms and their implementation (with two new commands) as provided by the `natbib` system.

<p>Knuth (1989) shows ... This is explained in the authoritative manual on \TeX (Knuth, 1986).</p>	<pre>\usepackage{natbib} \citet{Knuth:TB10-1-31} shows \ldots\ This is explained in the authoritative manual on \TeX{~}\citep{Knuth-CT-a}.</pre>
---	--

16-3-1

Extending the \LaTeX syntax for citing publications does not solve the problem completely. In order to produce the different forms of citation references needed in the author-date system, structured information must be provided by the bibliography. Without a special structure it is impossible to pick up the data needed for the textual references (e.g., producing just the year in parentheses). That is, a bibliographical entry like

```
\bibitem[Donald-E. Knuth 1986]{Knuth-CT-a} Donald-E. Knuth.
\newblock \emph{The {\TeX}book}, volume-A of \emph{Computers and
Typesetting}. \newblock Addison-Wesley, Reading, MA, USA, 1986.
```

allows the `\cite` command to produce “(Donald E. Knuth 1986)” but not “Donald E. Knuth (1986)” or just “Knuth” or just “1986” as well. You also have to ensure that `\bibitem` does not display the label, but that outcome can be fairly easily arranged.

The solution used by all implementations for author-date support before the advent of the `biblatex` package was to introduce a special syntax within the optional argument of `\bibitem`. In some implementations this structure is fairly simple. For instance, `chicago` requires only

```
\bibitem[\protect\citeauthoryear{Goossens, Rahtz, and Mittelbach}
{Goossens et~al.}{1997}]{LGC97}
```

This information can still be produced manually, if needed. Other packages go much further and encode a lot of information explicitly. For example, `jurabib` asks for the following kind of argument structure (same publication):

```
\bibitem[{{Goossens\jbbfsasep Rahtz\jbbstasep Mittelbach\jbdy {1997}}}%
{{0}}{book}{1997}}{xi + 554}{Reading, MA, USA\pubaddr {
Ad{\-d}i{\-s}on-Wes{\-l}ey Longman\bibbdsep {} 1997}}{The {\LaTeX}
Graphics Companion: Illustrating Documents with {\TeX} and {\PostScript}}%
{}{}{}{}{}{}{}]{LGC97}
```

This approach gives a lot of flexibility when referring to the publication, but it is clear that no one wants to produce a bibliography environment with such a structure

manually. The same is true when biblatex is used, only in this case the .bbl file no longer contains `\bibitem` commands with structured arguments, but just the structured data in a special format; see the introduction to Section 16.7 on page 541. While that format may be easier to understand than the one produced, for example, for `jurabib`, it is not realistic to generate it manually either. Hence, the only usable solution in these cases is to use an external tool, i.e., `biber` or `BibTeX` (together with special style files) to generate the entries automatically.

16.3.1 Early attempts

Over the years several independent add-on packages have been developed to support the author-date system. Unfortunately, each one introduced a different set of user-level commands. Typically, the add-ons consist of a \LaTeX package providing the user commands and one or more `BibTeX` styles to generate the `thebibliography` environment with a matching syntax in the optional argument of the `\bibitem` command.

For example, the `chicago` package, which aimed to implement the recommendations of *The Chicago Manual of Style* [40], offers the following list of commands (plus variants all ending in NP to omit the parentheses — for example, `\citeNP`):

	<code>\usepackage{chicago}</code>	
	<code>\bibliographystyle{chicago}</code>	
(Goossens, Rahtz, and Mittelbach 1997)	<code>\cite{LGC97}</code>	<code>\\</code>
(Goossens, Rahtz, and Mittelbach)	<code>\citeA{LGC97}</code>	<code>\\</code>
Goossens, Rahtz, and Mittelbach (1997)	<code>\citeN{LGC97}</code>	<code>\\</code>
(Goossens and Rahtz 1999)	<code>\shortcite{LWC99}</code>	<code>\\</code>
(Goossens and Rahtz)	<code>\shortciteA{LWC99}</code>	<code>\\</code>
Goossens and Rahtz (1999)	<code>\shortciteN{LWC99}</code>	<code>\\</code>
(1999), 1999	<code>\citeyear{LWC99}, \citeyearNP{LWC99}</code>	

16-3-2

Several `BibTeX` styles (`chicago`, `chicagoa`, `jas99`, `named`, and `newapa`) are compatible with the `chicago` package. All of them are still in use, but the package itself is now rarely included in \LaTeX documents (`natbib` can be used instead to provide the user-level syntax).

In contrast, only two commands are provided by David Rhead's `authordate1-4` package, the original support package for the `BibTeX` styles `authordate1` to `authordate4`. It implements recommendations by the Cambridge and Oxford University Presses and various British standards.

	<code>\usepackage{authordate1-4}</code>	
	<code>\bibliographystyle{authordate2}</code>	
(Goossens <i>et al.</i> , 1997) or (1997)	<code>\cite{LGC97}</code>	or <code>\shortcite{LGC97}</code>

16-3-3

For a final example we take a brief look at the `harvard` package by Peter Williams and Thorsten Schnier. In contrast to the two previously described packages, `harvard` has been further developed and updated for $\LaTeX 2_{\epsilon}$. It implements a number of

interesting features. For example, a first citation gives a full author list, whereas a later citation uses an abbreviated list (unless explicitly requested otherwise). The user-level commands are shown in the next example:¹

(Goossens, Rahtz & Mittelbach 1997)		<code>\usepackage{harvard}</code>	
(Goossens et al. 1997)	second citation	<code>\bibliographystyle{agsm}</code>	
(Goossens, Rahtz & Mittelbach 1997)	long names forced	<code>\cite{LGC97}</code>	<code>\\</code>
Goossens et al. (1997)		<code>\cite{LGC97} \hfill second citation</code>	<code>\\</code>
(e.g., Goossens et al. 1997)		<code>\cite*[LGC97]\hfill long names forced</code>	<code>\\</code>
Goossens et al.		<code>\citeasnoun{LGC97}</code>	<code>\\</code>
Knuth's (1986)		<code>\citeaffixed{LGC97}{e.g.,}</code>	<code>\\</code>
		<code>\citename{LGC97}</code>	<code>\\</code>
		<code>\possessivecite{Knuth-CT-a}</code>	

16-3-4

The harvard package requires a specially prepared bibliography environment in which `\bibitem` is replaced by `\harvarditem`, a command with a special syntax used to carry the information needed for author-date citations. A few \LaTeX styles (including `agsm`, `dcu`, `kluwer`, and `nederlands`) implement this special syntax.

Many of these packages support the author-date system quite well. Nevertheless, with different packages using their own syntax and supporting only half a dozen \LaTeX styles each, the situation stayed unsatisfactory for a long time. Matters changed for the better when Patrick Daly published his `natbib` support package, described in the next section.

16.3.2 natbib — Customizable author-date references

Although most publishers indicate which bibliographic style they prefer, it is not always evident how to change from one system to the other if one has to prepare source texts adhering to multiple styles.

To solve the problem of incompatible syntaxes described in the previous section, Patrick Daly developed the `natbib` package (for “NATural sciences BIBliography”). This package can accept several `\bibitem` variants (including `\harvarditem`) as produced by the different \LaTeX styles. Thus, for the first time, (nearly) all of the author-date \LaTeX styles could be used with a single user-level syntax for the citation commands.

The `natbib` package is compatible with packages like `babel`, `chapterbib`, `hyperref`, `index`, and `showkeys`, and with various document classes including the standard \LaTeX classes, `amsbook` and `amsart`, classes from the KOMA-Script bundle, and `memoir`. It cannot be used together with the `cite` package but provides similar sorting and compressing functions via options.

The `natbib` package therefore acts as a single, flexible interface for most of the available bibliographic styles for \LaTeX when the author-date system is required. It can also be used to produce numerical references; see Sections 16.2.4 and 16.4.1.

¹The small `har2nat` package allows using those commands also with `natbib`.

The basic syntax

The two central commands of `natbib` are `\citet` (for textual citation) and `\citep` (for parenthetical citation).¹

```
\citet[post-note]{key1,key2,...}   \citet[pre-note][post-note]{key1,...}
\citep[post-note]{key1,key2,...}   \citep[pre-note][post-note]{key1,...}
```

Both commands take one mandatory argument (a *key-list* that refers to one or more publications) and one or two optional arguments to add text before and after the citation. L^AT_EX's standard `\cite` command can take only a single optional argument denoting a *post-note*. For this reason the commands implement the following syntax: with only one optional argument specified, this argument denotes the *post-note* (i.e., a note placed after the citation); with two optional arguments specified, the first denotes a *pre-note* and the second a *post-note*. To get only a *pre-note* you have to add an empty second argument, as seen in the last lines of the next two examples. Also note that `natbib` redefines `\cite` to act like `\citet`.²

		<code>\usepackage{natbib}</code>	
Different <code>\citet</code> variants:		Different <code>\verb=\citet=</code> variants:	<code>\\[2pt]</code>
Goossens et al. (1997)		<code>\citet{LGC97}</code>	<code>\\</code>
Goossens et al. (1997, chap. 2)		<code>\citet[chap.~2]{LGC97}</code>	<code>\\</code>
Goossens et al. (see 1997, chap. 2)		<code>\citet[see][chap.~2]{LGC97}</code>	<code>\\</code>
16-3-5	pre-note only: Goossens et al. (see 1997)	<code>\citet[see][]{LGC97}</code>	
		<code>\usepackage{natbib}</code>	
Different <code>\citep</code> variants:		Different <code>\verb=\citep=</code> variants:	<code>\\[2pt]</code>
(Goossens et al., 1997)		<code>\citep{LGC97}</code>	<code>\\</code>
(Goossens et al., 1997, chap. 2)		<code>\citep[chap.~2]{LGC97}</code>	<code>\\</code>
(see Goossens et al., 1997, chap. 2)		<code>\citep[see][chap.~2]{LGC97}</code>	<code>\\</code>
16-3-6	pre-note only: (see Goossens et al., 1997)	<code>\citep[see][]{LGC97}</code>	

Both commands have starred versions, `\citet*` and `\citep*` (with otherwise identical syntax), that typeset the full list of authors if it is known.³ These variants work only if this feature is supported by the used B^BL^AT_EX style file. In other words, the information must be made available through the optional argument of `\bibitem`; if it is missing, the abbreviated list is always printed.

		<code>\usepackage{natbib}</code>	
Compare Goossens et al. (1997) with		Compare <code>\citet{LGC97}</code> with	<code>\\</code>
Goossens, Rahtz, and Mittelbach (1997)		<code>\citet*{LGC97}</code>	<code>\\</code>
16-3-7	(see Goossens, Rahtz, and Mittelbach, 1997)	<code>\citep*[see][]{LGC97}</code>	

¹The commands exhibit the same behavior in most bibliographic styles, which is why we do not show a `\bibliographystyle` line in many of the upcoming examples.

²To be precise, `\cite` is redefined to act like `\citet` if `natbib` is used in author-date mode as discussed in this section. If used in author-number mode (see Section 16.4.1), it works like `\citep`.

³If you plan to also use the `jurabib` package (see Section 16.5.1), then avoid the starred forms because they are not supported by that package.

Two other variant forms exist: `\citealt` works like `\citet` but does not generate parentheses, and `\citealp` is `\citep` without parentheses. Evidently, some of the typeset results come out almost identically.

	<code>\usepackage{natbib}</code>	
Goossens et al. 1997	<code>\citealt{LGC97}</code>	<code>\\</code>
Goossens et al., 1997	<code>\citealp{LGC97}</code>	<code>\\</code>
Goossens, Rahtz, and Mittelbach 1997	<code>\citealt*{LGC97}</code>	<code>\\</code>
Goossens, Rahtz, and Mittelbach, 1997	<code>\citealp*{LGC97}</code>	<code>\\</code>
Goossens and Rahtz, 1999, p. 236 etc.	<code>\citealp[p.~236]{LWC99}</code>	etc.

16-3-8

When using the author-date system, it is sometimes desirable to just cite the author(s) or the year. For this purpose `natbib` provides the following additional commands (`\citeauthor*` is the same as `\citeauthor` when the full author information is unavailable):

	<code>\usepackage{natbib}</code>	
Goossens et al.	<code>\citeauthor{LGC97}</code>	<code>\\</code>
Goossens, Rahtz, and Mittelbach	<code>\citeauthor*{LGC97}</code>	<code>\\</code>
1997 or (1997)	<code>\citeyear{LGC97}</code>	or <code>\citeyearpar{LGC97}</code>

16-3-9

Even more complex mixtures of text and citation information can be handled with the command `\citetext`. It takes one mandatory argument and surrounds it with the parentheses or brackets used by other citation commands. By combining this command with `\citealp` or other commands that do not produce parentheses, all sorts of combinations become possible.

(see Goossens et al., 1997 or Knuth,	<code>\usepackage{natbib}</code>	
1986)	<code>\citetext{see \citealp{LGC97} or \citealp{Knuth-CT-a}}</code>	

16-3-10

*Forcing names
to uppercase* 

Sometimes a sentence starts with a citation, but the (first) author of the cited publication has a name that starts with a lowercase letter. In that case, the commands discussed so far cannot be used. The `natbib` package solves this problem by providing for all commands variants that capitalize the first letter. They are easy to remember: just capitalize the first letter of the corresponding original command. For example, instead of `\citet*`, use `\Citet*`. Here are some additional examples:

	<code>\usepackage{natbib}</code>	
Normal citation: van Leunen (1992)	Normal citation: <code>\citet{vLeunen:92}</code>	<code>\\</code>
Van Leunen (1992) or Van Leunen 1992	<code>\Citet{vLeunen:92}</code> or <code>\Citealt{vLeunen:92}</code>	<code>\\</code>
(Van Leunen, 1992) or Van Leunen, 1992	<code>\Citep{vLeunen:92}</code> or <code>\Citealp{vLeunen:92}</code>	<code>\\</code>
Van Leunen	<code>\Citeauthor{vLeunen:92}</code>	

16-3-11

As a final goody, `natbib` lets you define alternative text for a citation that can be used instead of the usual author-date combination. For the definition use

`\defcitealias` (usually in the preamble), and for the retrieval use `\citetalias` or `\citepalias`.

	<code>\usepackage{natbib}</code>
	<code>\defcitealias{LGC97}{Dogbook-II}</code>
Goossens et al. (1997) = Dogbook II	<code>\citet{LGC97} = \citetalias{LGC97} \\\</code>
(Goossens et al., 1997) = (Dogbook II)	<code>\citep{LGC97} = \citepalias{LGC97} \\\par</code>
Alias changed: (see Dogbook II 2ed)	<code>\defcitealias{LGC97}{Dogbook-II~2ed}</code>
	Alias changed: <code>\citepalias[see] []{LGC97}</code>

With the commands introduced in this section, `natbib` provides more features than the earlier attempts to support the author-date system (e.g., the packages described in Section 16.3.1). In the few cases where `natbib` does not offer directly equivalent commands, they can be easily built manually.

For example, `harvard's` `\possessivecite` command (shown in Example 16-3-4) can be emulated with `\citeauthor` and `\citeyearpar`, as is done in the first line of the next example:

	<code>\usepackage{natbib}</code>
	<code>\bibliographystyle{agsm}</code>
	<code>\newcommand\possessivecite[1]{\citeauthor{#1}'s \citeyearpar{#1}}</code>
Knuth's (1986)	<code>\citeauthor{Knuth-CT-a}'s \citeyearpar{Knuth-CT-a} \\\</code>
Knuth's (1986)	<code>\possessivecite{Knuth-CT-a}</code>

Multiple citations

In standard \LaTeX , multiple citations can be made by including more than one citation *key-list* argument to the `\cite` command. The same is possible for the citation commands `\citet` and `\citep` (as well as their variant forms). The `natbib` package then automatically checks whether adjacent citations in the *key-list* have the same author designation. If so, it prints the author names only once. Unfortunately, it checks only the surnames; e.g., “Don Knuth” and “Jill Knuth” would be considered the same author and lumped together.

 Careful with different authors with identical surnames

	<code>\usepackage{natbib}</code>
Goossens et al. (1997); Goossens and Rahtz (1999)	<code>\citet{LGC97,LWC99} \\\</code>
(Goossens et al., 1997; Goossens and Rahtz, 1999)	<code>\citep{LGC97,LWC99} \\\</code>
(Knuth, 1989, 1986)	<code>\citep{Knuth:TB10-1-31,Knuth-CT-a}</code>

The last line in the previous example exhibits a potential problem when using several keys in one citation command: the references are typeset in the order of the *key-list*. If you specify the option `sort`, then the citations are sorted into the order in which they appear in the bibliography, usually alphabetical by author and then by year.

	<code>\usepackage[sort]{natbib}</code>
(Knuth, 1986, 1989)	<code>\citep{Knuth:TB10-1-31,Knuth-CT-a}</code>

While all the citation commands support *key-lists* with more than one citation key, they are best confined to `\citep`; already `\citet` gives questionable results. The situation gets worse when you use optional arguments: with `\citet` any *pre-note* is added before each year (which could be considered a defect in the package). More generally, it is not at all clear what these notes are supposed to refer to. Hence, if you want to add notes, it is better to separate your citations.

	<code>\usepackage{natbib}</code>	
(see van Leunen, 1992; Knuth, 1986, p. 55)	<code>\citep[see] [p.~55]{vLeunen:92,Knuth-CT-a}</code>	<code>\</code>
(see Knuth, 1986, 1989, p. 55)	<code>\citep[see] [p.~55]{Knuth-CT-a,Knuth:TB10-1-31}</code>	<code>\</code>
van Leunen (see 1992); Knuth (see 1986, p. 55)	<code>\citet[see] [p.~55]{vLeunen:92,Knuth-CT-a}</code>	<code>\</code>
Knuth (see 1986, 1989, p. 55)	<code>\citet[see] [p.~55]{Knuth-CT-a,Knuth:TB10-1-31}</code>	

16-3-16

Full author list only with the first citation

The harvard package automatically typesets the first citation of a publication with the full list of authors and subsequent citations with an abbreviated list. This style of citation is quite popular in some disciplines, and `natbib` supports it if you load it with the option `longnamesfirst`. Compare the next example to Example 16-3-4 on page 490:

	<code>\usepackage[longnamesfirst]{natbib}</code>	
	<code>\bibliographystyle{agsm}</code>	
(Goossens, Rahtz & Mittelbach 1997) first citation	<code>\citep{LGC97} \hfill first citation</code>	<code>\</code>
(Goossens et al. 1997) second	<code>\citep{LGC97} \hfill second</code>	<code>\</code>
(Goossens, Rahtz & Mittelbach 1997) names forced	<code>\citep*{LGC97}\hfill names forced</code>	<code>\</code>
Goossens et al. (1997)	<code>\citet{LGC97}</code>	<code>\</code>
(e.g., Goossens et al. 1997)	<code>\citep[e.g.,] []{LGC97}</code>	<code>\</code>
Goossens et al.	<code>\citeauthor{LGC97}</code>	

16-3-17

Some Bib_T_EX style files are quite cleverly programmed. For example, when the `agsm` Bib_T_EX style, used in Example 16-3-17, detects that shortening a list of authors leads to ambiguous citations, it refuses to produce an abbreviated list. Thus, after adding the `test97` citation to the example, all citations suddenly come out in long form.¹ Bib_T_EX styles produced with `custom-bib` avoid such ambiguous citations by adding a suffix to the year, but other Bib_T_EX styles (e.g., `chicago`) happily produce them; see Example 16-3-19 on the facing page and page 471.

	<code>\usepackage[longnamesfirst]{natbib}</code>	
	<code>\bibliographystyle{agsm}</code>	
(Goossens, Rahtz & Mittelbach 1997) first citation	<code>\citep{LGC97} \hfill first citation</code>	<code>\</code>
(Goossens, Rahtz & Mittelbach 1997) second	<code>\citep{LGC97} \hfill second</code>	<code>\</code>
(Goossens, User, Doe et al. 1997) first citation	<code>\citep{test97}\hfill first citation</code>	<code>\</code>
(Goossens, User, Doe et al. 1997) second citation	<code>\citep{test97}\hfill second citation</code>	

16-3-18

¹Something that puzzled the author when he first encountered it while preparing the examples.

Some publications have so many authors that you may want to always cite them using their abbreviated name list, even the first time. You can achieve this effect by listing their keys, separated by commas, in the argument of a `\shortcites` declaration made in the preamble. The example also shows that use of the `chicago` style can lead to ambiguous citations (lines 1 and 2 versus line 5).

		<code>\usepackage[longnamesfirst]{natbib}</code>
		<code>\bibliographystyle{chicago}</code>
		<code>\shortcites{LGC97}</code>
(Goossens et al., 1997)	first citation	<code>\citep{LGC97} \hfill first citation \\\</code>
(Goossens et al., 1997)	second citation	<code>\citep{LGC97} \hfill second citation \\\</code>
(Goossens, Rahtz, and Mittelbach, 1997)	forced	<code>\citep*{LGC97}\hfill forced \\\</code>
(Goossens, User, Doe, et al., 1997)	first citation	<code>\citep{test97}\hfill first citation \\\</code>
(Goossens et al., 1997)	second citation	<code>\citep{test97}\hfill second citation</code>

16-3-19

Customizing the citation reference layout

So far, all of the examples have shown parentheses around the citations, but this is by no means the only possibility offered by `natbib`. The package internally knows about more than 20 `BBTEX` styles. If any such style is chosen with a `\bibliographystyle` command, then a layout appropriate for this style is selected as well. For example, when using the `agu` (American Geophysical Union) style, we get:

<i>Goossens et al.</i> [1997]	<code>\usepackage{natbib} \bibliographystyle{agu}</code>
[<i>Knuth</i> , 1986; <i>Goossens and Rahtz</i> , 1999]	<code>\citet{LGC97} \\\ \citep{Knuth-CT-a,LWC99} \\\</code>
[see <i>Knuth</i> , 1986, chap. 2]	<code>\citep[see] [chap.~2] {Knuth-CT-a}</code>

16-3-20

By default, the citation layout is determined by the chosen `BBTEX` style (or `natbib`'s defaults if a given style is unknown to `natbib`). By including a `\citestyle` declaration you can request use of the citation style associated with a `BBTEX` style that is different from the one used to format the bibliography. In the next example we use the `agsm` style for the citations while the overall style remains `agu`. If you compare this example to Example 16-3-20, you see that the textual formatting is unchanged (e.g., italic for author names), but the parentheses and the separation between authors and year have both changed.

<i>Goossens et al.</i> (1997)	<code>\usepackage{natbib} \bibliographystyle{agu}</code>
(<i>Knuth</i> 1986, <i>Goossens and Rahtz</i> 1999)	<code>\citestyle{agsm}</code>
(see <i>Knuth</i> 1986, chap. 2)	<code>\citet{LGC97} \\\ \citep{Knuth-CT-a,LWC99} \\\</code>
	<code>\citep[see] [chap.~2] {Knuth-CT-a}</code>

16-3-21

It is also possible to influence the layout by supplying options: `round` (default for most styles), `square`, `curly`, or `angle` change the type of parentheses used, while `colon`¹ (default for most styles) and `comma` alter the separation between multiple

¹Despite its name this option produces a “;” semicolon.

citations. In the next example, we overwrite the defaults set by the `agu` style, by loading `natbib` with two options.

<code>Goossens et al. {1997}</code> <code>{Knuth, 1986, Goossens and Rahtz, 1999}</code> <code>{see Knuth, 1986, chap. 2}</code>	<pre>\usepackage[curly,comma]{natbib} \bibliographystyle{agu} \citestyle{LGC97} \\\citep{Knuth-CT-a,LWC99} \\\ \citep[see][chap.~2]{Knuth-CT-a}</pre>
--	---

16-3-22

Yet another method to customize the layout is mainly intended for package and/or class file writers: the `\bibpunct` declaration. It takes seven arguments (the first optional) that define various aspects of the citation format. It is typically used to define the default citation format for a particular \LaTeX style. For example, the `natbib` package contains many definitions like this:

```
\newcommand\bibstyle@chicago{\bibpunct{()}{;}{a}{,}{,}{,}}
```

That definition is selected when you choose `chicago` as your \LaTeX style or when you specify it as the argument to `\citestyle`. Similar declarations can be added for \LaTeX styles that `natbib` does not directly support. This effect is most readily realized by grouping such declarations in the local configuration file `natbib.cfg`. For details on the meanings of the arguments, see the documentation accompanying the `natbib` package.

If there are conflicting specifications, then the following rules apply: the lowest priority is given to internal `\bibstyle@(<name>)` declarations, followed by the options specified in the `\usepackage` declarations. Both are overwritten by an explicit `\bibpunct` or `\citestyle` declaration in the document preamble.

Normally, `natbib` does not prevent a line break within the author list of a citation. By specifying the option `nonamebreak`, you can ensure that all author names in one citation are kept on a single line. In normal circumstances this is seldom a good idea because it is likely to cause overfull hboxes.

Forcing all author
names on a single
line

Customizing the bibliography layout

The `thebibliography` environment, as implemented by `natbib`, automatically adds a heading before the list of publications. By default, `natbib` selects an unnumbered heading of the highest level, such as `\chapter*` for a book type class or `\section*` for the article class or a variant thereof. The actual heading inserted is stored in the command `\bibsection`. Thus, to modify the default, you have to change its definition. For instance, you can suppress the heading altogether or choose a numbered heading.

For one particular situation `natbib` offers direct support: if you specify the option `sectionbib`, you instruct the package to use `\section*`, even if the highest sectional unit is `\chapter`. This option is useful if `natbib` and `chapterbib` are used together (see Section 16.8.1).

Between `\bibsection` and the start of the list, `natbib` executes the hook `\bibpreamble`. It allows you to place some text between the heading and the start

of the actual reference list. It is also possible to influence the font used for the bibliography by redefining the command `\bibfont`. This hook can also be used to influence the list in other ways, such as setting it unjustified by adding `\raggedright`. Note that `\bibpreamble` and `\bibfont` are defined by default (to do nothing) and thus require redefining with `\renewcommand`.

Finally, two length parameters are available for customization. The first line in each reference is set flush left, and all following lines are indented by the value stored in `\bibhang` (default 1em). The vertical space between the references is stored in the rubber length `\bibsep` (the default value is usually equal to `\itemsep` as defined in other lists).

To show the various possibilities available we repeat Example 16-1-2 on page 472 but apply all kinds of customization features (not necessarily for the better!). Note the presence of `\par` at the end of `\bibpreamble`. Without it the settings in `\bibfont` would affect the inserted text!

Entries with multiple authors might be problematical, e.g., Goossens et al. [1997a] and Goossens et al. [1997b] or even Goossens et al. [1997a,b]. But then they might not.

16-3-23

Publications without author or year information

To use the author-date citation system, the entries in your list of publications need to contain the necessary information. If some information is missing, citations with `\citet` or its variants may produce strange results.

If the publication has no author but an editor, then most B^BT_EX styles use the latter. However, if both are missing, the solutions implemented differ greatly. B^BT_EX files in “Harvard” style (e.g., `agsm`) use the first three letters from the key field if present; otherwise, they use the first three letters from the organization field (omitting “The_” if necessary); and if that field is not available, they use the full title. If an entry has no year, then “n.d.” is used. This results in usable entries except in the case where part of the key field is selected:

Koppitz (n.d.) / *TUGboat The Communications of the T_EX User Group* (1980ff) / mak (2000)

```
\usepackage{natbib} \bibliographystyle{agsm}
\citet{G-G} / \citet{oddtity} / \citet{GNUMake}
```

16-3-24

With the same entries, BibTeX styles produced with custom-bib (e.g., `unsrtnat`) use the following strategy: if a key field is present, the whole field is used as an “author”; otherwise, if an organization field is specified, its first three letters are used (omitting “The_” if necessary); and if the entry does not have such a field, the first three letters of the citation label are used. A missing year is completely omitted. In the case of textual citations, this means that only the author name is printed. In that situation, or when the key field is used, it is probably best to avoid `\citet` and always use `\citep` to make it clear to the reader that you are actually referring to a publication and not just mentioning some person in passing.

```

\usepackage{natbib} \bibliographystyle{unsrtnat}
Koppitz / odd [1980ff] / make \citet{G-G} / \citet{oddity} / \citet{GNUMake} \
[Koppitz] / [odd, 1980ff] / [make] \citep{G-G} / \citep{oddity} / \citep{GNUMake}

```

16-3-25

As a final example we show the results when using the `chicago` BibTeX style. Here the GNU manual comes out fine (the full organization name is used), but the entry with the date missing looks odd.

```

Koppitz (Koppitz) / odd (80ff) / Free Software
Foundation (2000) \usepackage{natbib} \bibliographystyle{chicago}
(Koppitz, Koppitz) / (odd, 80ff) / (Free Soft- \citet{G-G} / \citet{oddity} / \citet{GNUMake} \
ware Foundation, 2000) \citep{G-G} / \citep{oddity} / \citep{GNUMake}

```

16-3-26

Indexing citations automatically

Citations can be entered in the index by inserting a `\citeindextrue` command at any point in the document. From that point onward, and until the end of the current group or the next `\citeindexfalse` is encountered, all variants of the `\citet` and `\citep` commands generate entries in the index file (if one is written). With `\citeindextrue` in effect, the `\bibitem` commands in the `thebibliography` environment also generate index entries. If this result is not desired, issue a `\citeindexfalse` command before entering the environment (e.g., before calling `\bibliography`).

The format of the generated index entries is controlled by the internal command `\NAT@idxtxt`. It has the following default definition:

```
\newcommand\NAT@idxtxt{\NAT@name\ \NAT@open\NAT@date\NAT@close}
```

Thus, it produces entries like “Knuth (1986)” or “Knuth [1986]”. For citations without author or year information, the results will most likely come out strangely. If enabled, the citations in Example 16-3-25 would generate the following entries:

```

\indexentry{{Koppitz}\ []}{6}
\indexentry{{odd}\ [1980ff]}{6}
\indexentry{{make}\ []}{6}

```

Sadly, the index entries generated in this way are not quite correct: as you can see above, `\NAT@name` contains braces around the name, which makes such index entries sort under “Symbols” and not under their alphabetic letter.

This might be corrected in the future, but in all likelihood you want to alter the outcome anyway and put only the author’s name into the index. This can be done with the following declaration in the preamble (it also removes the disturbing braces around the names):

```
\makeatletter
\AtBeginDocument{\renewcommand\NAT@idxtxt{%
  \expandafter\@firstofone\NAT@name{}}% drops the braces
% \ \NAT@open\NAT@date\NAT@close      % uncomment, if you also want the date
}}
\makeatother
```

The `\makeatletter` and `\makeatother` are needed because internal commands are involved, and `\AtBeginDocument` is needed because the redefinition is otherwise overwritten again at `\begin{document}`.

It is also possible to produce a separate index of citations by using David Jones’s index package (see Section 14.5.3). It allows you to generate multiple index lists using the `\newindex` command. For this to work you must first declare the list and then associate automatic citation indexing with this list in the preamble:

```
\usepackage{index}
\newindex{default}{idx}{ind}{Index}           % the main index
\newindex{cite}{cdx}{cnd}{Index of Citations}
\renewcommand\citeindextype{cite}
```

Later, use `\printindex[cite]` to indicate where the citation index should appear in the document.

BibTeX styles for natbib

As mentioned in the introduction, `natbib` was developed to work with various BibTeX styles that implement some form of author-date scheme. In addition to those third-party styles, `natbib` works with all styles that can be produced with the `custom-bib` bundle (see Section 15.7.2 on page 426). It is distributed with three styles — `abbrvnat`, `plainnat`, and `unsrtnat` — that are extensions of the corresponding standard styles. They have been adapted to work better with `natbib`, allowing you to use some of its features that would be otherwise unavailable. These styles also implement a number of extra fields useful in the days of electronic publications:

doi For use with electronic journals and related material. The Digital Object Identifier (DOI) is a system for identifying and exchanging intellectual property in the digital environment and is supposedly more robust than Uniform Resource Locators (URLs); see www.doi.org for details. The field is optional.

eid Because electronic journals usually have no page numbers, they use a sequence identifier (EID) to locate the article within the journal. The field is optional and is used in place of the page number if present.

isbn The International Standard Book Number (ISBN), a 13-digit (formerly 10) unique identification number (see <https://www.isbn.org>). The ISBN is defined in ISO Standard 2108 and has been in use for more than 50 years. The field is optional.

issn The International Standard Serial Number (ISSN), an 8-digit number that identifies periodical publications (see <https://www.issn.org>). The field is optional.

url The Uniform Resource Locator (URL) for identifying resources on the web. The field is optional. Because URL addresses are typically quite long and are set in a typewriter font, line-breaking problems may occur. They are therefore automatically surrounded with a `\url` command, which is given a simple default definition if undefined. Thus, by using the `url` package (see Section 3.4.7), you can drastically improve the line-breaking situation because then URLs can be broken at punctuation marks.

16.3.3 biblatex's approach to author-date references

The `biblatex` package ships with the styles `authoryear`, `authoryear-comp`, `authoryear-ibid`, and `authoryear-icomp`, and many additional author-date styles are provided by external packages as shown in the overview of styles in Section 15.7.3. With the exception of the styles from the `biblatex-chicago` package, all can be loaded in the package options with the key `style`.

Besides `\cite`, the `biblatex` package offers a large variety of citation commands including variants to access only parts of the citation; and as with `natbib` all commands have two optional arguments for the pre- and post-note. We demonstrate a few variants in the following example. Note that differently than `natbib`, the starred command `\citeauthor*` shows the shortened author list.

The `\textcite` variants:

Goossens, Rahtz, and Mittelbach (1997, chap. 2)
 Goossens, Rahtz, and Mittelbach (see 1997, chap. 2)
 Goossens, Rahtz, and Mittelbach (see 1997)

Other commands:

(see Goossens, Rahtz, and Mittelbach 1997, chap. 2)
 see Goossens, Rahtz, and Mittelbach 1997, chap. 2
 see 1997, chap. 2
 Goossens, Rahtz, and Mittelbach
 Goossens et al.
 1997

```
\usepackage[style=authoryear]{biblatex}
\addbibresource{t1c.bib}
```

```
The \verb=\textcite= variants: \[2pt]
\textcite[chap.~2]{LGC97}      \[
\textcite[see][chap.~2]{LGC97} \[
\textcite[see][]{LGC97}        \[12pt]
Other commands:                \[2pt]
\parencite[see][chap.~2]{LGC97} \[
\cite[see][chap.~2]{LGC97}      \[
\cite*[see][chap.~2]{LGC97}     \[
\citeauthor{LGC97}              \[
\citeauthor*{LGC97}             \[
\citeyear{LGC97}
```

16-3-27

The `authoryear-comp` style sorts and compresses citation lists, while the style `authoryear-ibid` uses “ibidem” for repeated citations. The `authoryear-icomp` style combines both approaches:

 *The biblatex approach to the cite package*

16-3-28

```

Goossens and Rahtz (1999), Goossens, Rahtz,
and Mittelbach (1997), and Knuth (1986, 1989)
Knuth (see 1986)
Knuth (see ibid.)
\usepackage[style=authoryear-icomp]{biblatex}
\addbibresource{tlc.bib}
\textcite{LGC97,Knuth-CT-a,LWC99,Knuth:TB10-1-31}\
\textcite[see][]{Knuth-CT-a} \
\textcite[see][]{Knuth-CT-a} \

```

The package provides citation commands that capitalize the first letter of a citation. As with `natbib` they are easy to remember: just capitalize the first letter of the corresponding original command. By default `biblatex` prints author names without a prefix in a citation; we change this with the option `useprefix` to show the effect.

 *Forcing names to uppercase*

16-3-29

```

Normal citation: van Leunen (1992)
Van Leunen (1992)
(Van Leunen 1992)
Van Leunen
\usepackage[style=authoryear,useprefix]{biblatex}
\addbibresource{tlc.bib}
Normal citation: \textcite{vLeunen:92}\
\Textcite{vLeunen:92} \
\Parencite{vLeunen:92} \
\Citeauthor{vLeunen:92}

```

The number of authors shown in citations can be globally adjusted with the options `maxcitenames` and `mincitenames`. In the document you can alter the setup for individual citations, e.g., to show more authors in one citation. There, it is done by setting the counters `maxnames` and `minnames` to suitable values. These counters are reset by `biblatex` at the start of every citation command, which means that setting them on the top level has no effect. Instead, you need to do this inside `\AtNextCite`, as shown below:

16-3-30

```

Goossens et al. (1997)
Goossens, Rahtz, et al. (1997)
Goossens et al. (1997)
Goossens, Rahtz, and Mittelbach
(1997)
\usepackage[style=authoryear,
maxcitenames=1]{biblatex}
\addbibresource{tlc.bib}
\textcite{LGC97} \
\AtNextCite{\setcounter{minnames}{2}}%
\setcounter{maxnames}{2}}\textcite{LGC97} \
\textcite{LGC97} \
\AtNextCite{\setcounter{maxnames}{99}}\textcite{LGC97}

```

Remember that the author names and the year build a label that should allow the reader to find the entry in the bibliography. `biblatex` tries hard to ensure that this label is unique and if needed increases the number of authors or adds initials. Check the `uniquename` and `uniquelist` options shown in the introduction of this chapter in Example 16-1-3 and discussed in more detail in Section 16.7.7 if `biblatex` seems to ignore your `maxnames` setting.

The `biblatex` package offers various “multicite” commands — typically ending with a plural “s” — which allow adding an individual *pre-note* and *post-note* to all citations of a list. The following example shows a few variants. Similar to the `natbib`

Multiple citations

commands, the biblatex commands `\textcite` and `\textcites` add the *pre-note* before the year, and the output is rather questionable.

	<code>\usepackage[style=authoryear-comp]{biblatex}</code>	
	<code>\addbibresource{tlc.bib}</code>	
1: see Knuth 1986, p. 55; also Knuth 1989, p. 35	1: <code>\cites[see][55]{Knuth-CT-a}</code>	
2: Knuth 1989, p. 35, 1986, p. 55	<code>[also][35]{Knuth:TB10-1-31}\</code>	
3: (see Knuth 1986, p. 55; also Knuth 1989, p. 35)	2: <code>\cites[35]{Knuth:TB10-1-31}[55]{Knuth-CT-a}</code>	<code>\</code>
4: (Knuth 1989, p. 35, 1986, p. 55)	3: <code>\parencites[see][55]{Knuth-CT-a}</code>	<code>[also][35]{Knuth:TB10-1-31}</code>
5: Leunen (see 1992, p. 55) and Knuth (also 1986, p. 43)	4: <code>\parencites[35]{Knuth:TB10-1-31}[55]{Knuth-CT-a}\</code>	<code>\</code>
5: Knuth (see 1986, p. 55) and Knuth (also 1989, p. 43)	5: <code>\textcites[see][55]{vLeunen:92}</code>	
	<code>[also][43]{Knuth-CT-a}</code>	<code>\</code>
	5: <code>\textcites[see][55]{Knuth-CT-a}</code>	
	<code>[also][43]{Knuth:TB10-1-31}</code>	

16-3-31

*Full author list only
with the first citation*

The biblatex package has no built-in package option to get the full author list only with the first citation, but a similar effect can be achieved by activating the option `citetracker` and then checking at every cite key with the command `\ifciteseen` if a cite has already been seen:

	<code>\usepackage[style=authoryear,</code>
	<code>citetracker=true,maxnames=2]{biblatex}</code>
	<code>\addbibresource{tlc.bib}</code>
	<code>\AtEveryCitekey{%</code>
Goossens, Rahtz, and Mittelbach (1997)	<code>\ifciteseen{}\setcounter{maxnames}{99}}}</code>
Goossens et al. (1997)	<code>\textcite{LGC97} \ \ \textcite{LGC97}</code>

16-3-32

*Publications without
author or year
information*

If the publication has no author but an editor, the `authoryear` styles of biblatex uses the latter; if both are missing, the title is used. The field key is not used; thus, in the following example, which repeats Example 16-3-24, both entries without authors and editors use the title. If an entry has no year, then “n.d.” is used. The string is localized and so uses the german “o.D.” (for “ohne Datum”) in the next example.

1: Koppitz (o. D.)	<code>\usepackage[style=authoryear]{biblatex}</code>
2: <i>TUGboat The Communications of the</i>	<code>\usepackage[ngerman]{babel}</code>
<i>T_EX User Group</i> (1980ff)	<code>\addbibresource{tlc.bib} \addbibresource{tlc-ex.bib}</code>
3: <i>GNU Make, A Program for Directing</i>	1: <code>\textcite{G-G}</code>
<i>Recompilation</i> (2000)	2: <code>\textcite{oditty}</code>
	3: <code>\textcite{GNUmake}</code>

16-3-33

16.4 The author-number system

As mentioned in the introduction, no BibT_EX style file to our knowledge exists that implements the author-number system for documents in which the publications should be numbered individually for each author; for this you have to turn to a

biblatex style presented at the end of the section. If, however, the publications are numbered sequentially throughout the whole bibliography, then ample support is provided by BibTeX and by the natbib package already encountered in conjunction with the author-date system.

16.4.1 natbib — Revisited

Although originally designed to support the author-date system, natbib is also capable of producing author-number and number-only references. Both types of references are provided with the help of BibTeX styles specially designed for numbered bibliographies, similar to the BibTeX styles normally used for the author-date style of citations.

By default, natbib produces author-date citations. If you are primarily interested in citing references according to the number-only or author-number system, load natbib with the `numbers` option.

For comparison, we repeat Example 16-3-5 on page 491 with the `numbers` option loaded. This option automatically implies the options `square` and `comma`; thus, if you prefer parentheses, use the option `round` and overwrite the default choice.

	<code>\usepackage[numbers]{natbib}</code>	
Goossens et al. [1]	<code>\citet{LGC97}</code>	<code>\\</code>
Goossens et al. [1, chap. 2]	<code>\citet[chap.~2]{LGC97}</code>	<code>\\</code>
Goossens et al. [see 1, chap. 2]	<code>\citet[see][chap.~2]{LGC97}</code>	<code>\\</code>
pre-note only: Goossens et al. [see 1]	<code>pre-note only: \citet[see][]{LGC97}</code>	<code>\\[5pt]</code>
[1]	<code>\citep{LGC97}</code>	<code>\\</code>
[1, chap. 2]	<code>\citep[chap.~2]{LGC97}</code>	<code>\\</code>
[see 1, chap. 2]	<code>\citep[see][chap.~2]{LGC97}</code>	<code>\\</code>
pre-note only: [see 1]	<code>pre-note only: \citep[see][]{LGC97}</code>	

16-4-1

As you can see, the `\citet` command now generates citations according to the author-number system, while `\citep` produces number-only citations. In fact, if natbib is set up to produce numerical citations, L^AT_EX's `\cite` command behaves like `\citep`. In author-date mode, natbib makes this command act as the short form for the command `\citet`.

All variant forms of `\citet` and `\citep`, as discussed in Section 16.3.2, are also available in numerical mode, though only a few make sense. For example, `\citep*` gives the same output as `\citep`, because there are no authors inside the parentheses.

	<code>\usepackage[numbers]{natbib}</code>	
Goossens, Rahtz, and Mittelbach [1]	<code>\citet*{LGC97}</code>	<code>\\</code>
Goossens et al.	<code>\citeauthor{LGC97}</code>	<code>\\</code>
Goossens, Rahtz, and Mittelbach	<code>\citeauthor*{LGC97}</code>	<code>\\</code>
1997 or [1997]	<code>\citeyear{LGC97}</code> or <code>\citeyearpar{LGC97}</code>	

16-4-2

The commands `\citealt` and `\citealt*` should probably not be used, because without the parentheses the citation number is likely to be misinterpreted. However,

in certain situations `\citealp` might be useful to obtain that number on its own and then perhaps use it together with `\citetext`.

	<code>\usepackage[numbers]{natbib}</code>	
Goossens et al. 1	<code>\citealt{LGC97}</code>	<code>\\</code>
Goossens, Rahtz, and Mittelbach 1	<code>\citealt*{LGC97}</code>	<code>\\</code>
1	<code>\citealp{LGC97}</code>	<code>\\</code>
1, p. 236 etc.	<code>\citealp[p.~236]{LGC97}</code>	etc.

16-4-3

Some journals use numerical citations with the numbers raised as superscripts. If loaded with the option `super`, the `natbib` package supports this type of citation. In that case our standard example (compare with Example 16-4-1) gives this:

	<code>\usepackage[super]{natbib}</code>	
Goossens et al. ¹	<code>\citet{LGC97}</code>	<code>\\</code>
Goossens et al. ¹ , chap. 2	<code>\citet[chap.~2]{LGC97}</code>	<code>\\</code>
Goossens et al. see ¹ , chap. 2	<code>\citet[see][chap.~2]{LGC97}</code>	<code>\\</code>
pre-note only: Goossens et al. see ¹	<code>\citet[see] []{LGC97}</code>	<code>\\</code>
1	<code>pre-note only: \citet[see] []{LGC97}</code>	<code>\\[5pt]</code>
¹ chap. 2	<code>\citep{LGC97}</code>	<code>\\</code>
see ¹ chap. 2	<code>\citep[chap.~2]{LGC97}</code>	<code>\\</code>
pre-note only: see ¹	<code>\citep[see][chap.~2]{LGC97}</code>	<code>\\</code>
	<code>pre-note only: \citep[see] []{LGC97}</code>	

16-4-4

As you will observe, the use of the optional arguments produces somewhat questionable results; in the case of `\citep` the *pre-note* does not appear at all. Thus, with this style of citation, it is usually best to stick to the basic forms of any such commands.

For superscript citations `natbib` removes possible spaces in front of the citation commands so as to attach the number to the preceding word. However, in contrast to the results produced with the `cite` package, punctuation characters do not migrate in front of the citation, nor is there any check for double periods. To illustrate this we repeat Example 16-2-15 from page 482.

...Knuth's book ² ; see also	<code>\usepackage[super]{natbib}</code>	
Goossens et al. ¹ .	<code>\ldots Knuth's book~\citep{Knuth-CT-a}; see also \citet{LGC97}.</code>	
...Knuth's book; ² see also	<code>\par %%% Manually corrected in two places:</code>	
Goossens et al. ¹	<code>\ldots Knuth's book;\citep{Knuth-CT-a} see also \citet{LGC97}</code>	

16-4-5

The packages `natbib` and `cite` are unfortunately incompatible (both modify \LaTeX 's internal citation mechanism), so in cases like Example 16-4-5 you have to change the input if `natbib` is to be used.

Sorting and compressing numerical citations

As seen in Section 16.2.2 the `cite` package sorts multiple citations and optionally compresses them into ranges. This feature is also implemented by `natbib` and can be activated through the options `sort` and `sort&compress`.

We have already encountered `sort` in connection with author-date citations. With numerical citations (i.e., the options `numbers` and `super`), the numbers are sorted. To show the effect we repeat Example 16-2-8 from page 478, except that we omit the undefined citation.

Good information about \TeX and \LaTeX can be found in [1, 2, 3, 4].

```
\usepackage[sort]{natbib} \bibliographystyle{plain}
Good information about \TeX{} and \LaTeX{} can be found in
\citep{LGC97,LWC99,Knuth-CT-a,Knuth:TB10-1-31}.
```

16-4-6

With the option `sort&compress`, the numbers are not only sorted but also compressed into ranges if possible. In author-date citation mode, this option has the same effect as `sort`.

Good information about \TeX and \LaTeX can be found in [1–4].

```
\usepackage[sort&compress]{natbib}\bibliographystyle{plain}
Good information about \TeX{} and \LaTeX{} can be found in
\citep{LGC97,LWC99,Knuth-CT-a,Knuth:TB10-1-31}.
```

16-4-7

The rules for selecting numerical mode

As mentioned previously, `natbib`, by default, works in author-date mode. However, for the previous two examples, `natbib` selected numerical mode without being explicitly told to do so (via the `numbers` or `super` option). This result occurs because the `plain` \BibTeX style does not carry author-date information in the `\bibitem` commands it generates. Whenever there is a single `\bibitem` without the relevant information, `natbib` automatically switches to numerical mode. Even specifying the option `authoryear` does not work in that case.

If a \BibTeX style supports author-date mode, then switching to numerical mode can be achieved by one of the following methods, which are listed here in increasing order of priority:

1. By selecting a `\bibliographystyle` with a predefined numerical citation style (e.g., defined in a local configuration file or in a class or package file).
2. By specifying the option `numbers` or `super`, as shown in most examples in this section.
3. By explicitly using `\bibpunct` with the fourth mandatory argument set to `n` or `s` (for details, see the package documentation).
4. By explicitly using `\citestyle` with the name of a predefined numerical bibliography style.

Customizing `natbib` in numerical mode

The majority of options and parameters to customize `natbib` have already been discussed on pages 495–497, but in numerical mode there are two more commands available to modify the produced layout. By default, citation numbers are typeset in the main body font. However, if you redefine `\citenumfont` (a command with one argument), it formats the citation number according to its specification.

Similarly, you can manipulate the format of the number as typeset within the bibliography by redefining `\bibnumfmt`. The default definition for this command usually produces square brackets around the number.

Images are discussed elsewhere, see (1, 2).

2. D. E. Knuth. *The T_EXbook*, volume A of *Computers and Typesetting*. Addison-Wesley, Reading, MA, USA, 1986. ISBN 0-201-13447-0.

```
\usepackage[numbers,round]{natbib}
\bibliographystyle{abbrvnat}
\renewcommand\bibfont{\small\raggedright}
\setlength\bibhang{30pt} % ignored!
\setlength\bibsep{1pt plus 1pt}
\renewcommand\citenumfont[1]{\textbf{#1}}
\renewcommand\bibnumfmt[1]{\textbf{#1.}}
```

Images are discussed elsewhere,
see \cite{LGC97,Knuth-CT-a}.

```
\bibliography{t1c}
```

16-4-8

While `\bibsection`, `\bibpreamble`, `\bibfont`, and `\bibsep` work as before, the parameter `\bibhang` has no effect, because in a numbered bibliography the indentation is defined by the width of the largest number.

16.4.2 biblatex's approach to author-number references

Nothing special is needed to get references with author names and numbers similar to the natbib output. Because biblatex always has access to the author names, you need only to use a numeric style and a citation command, which shows also the author like `\textcite` (or the emulated natbib commands if you have activated them with the natbib option). How many authors are shown can be set with the options `maxcitenames` and `mincitenames`. More examples and information about the numeric styles can be found in Section 16.2.5.

16-4-9

Numbering by
author

A style to number not throughout the bibliography but on a per-author (or author group) basis is provided by the biblatex-ext package. It makes use of a special field `extraname` that is generated by biber¹ if an author is cited with more than one work and allows one to differentiate them. We show the style in action in the next example. It also changes the delimiter between the author name and the number to a newline,

¹The style does not work with the Bib_T_EX backend.

changes the period after the number to a space, and removes the dash normally inserted when a author is repeated.

16-4-10

16.5 The author-title system

We now turn to the author-title system, sometimes also called the short-title system. A reference containing the author names and the title allows easy identification of the work while reading but generates longer citations than an author-date or numeric style. Styles therefore often use in subsequent citations abbreviations such as shorter titles, special shorthands, or words like “ibidem” to reference a repeated citation. Due to those additional requirements, the system is supported neither in standard L^AT_EX nor with the natbib package.

We start this section with a description of the jurabib package. As the name implies, the package has various options to tweak the output to conform to the citation rules in (German) jurisdiction, but it can also be used in other fields. This is then followed with a description of biblatex’s approach to the author-title system.

16.5.1 jurabib — Customizable short-title references

Classifying the jurabib package developed by Jens Berger as a package implementing the short-title system is not really doing it justice (no pun intended), because in fact it actually supports other citation systems as well.

Besides short-title citations, it offers support for author-date citations (by providing the natbib command interface), various options to handle specific requirements from the humanities, and special support for citing juridical works such as commentaries (hence the name jurabib).

The package uses an extended option concept where options are specified with a key/value syntax. It supports more than 30 options, each of which may be set to a number of values, covering various aspects of presenting the citation layout in the text and the references in the bibliography. In this book we can show only a small selection

of these possibilities. For further information refer to the package documentation, which is available in English and German.

*The defaults used
for all examples in
this section!*

It is inconvenient to handle so many options as part of the `\usepackage` declaration, so `jurabib` offers the `\jurabibsetup` command as an alternative. It can be used in the preamble or in the package configuration file `jurabib.cfg` (to set the defaults for all documents). Settings established when loading the package or via `\jurabibsetup` in the preamble overwrite such global defaults. For the examples in this section we use the following defaults

```
\jurabibsetup{titleformat=colonsep,commabeforerest=true}
```

and extend or overwrite them as necessary. The `titleformat` setting puts a colon between authors and title (see Example 16-5-7 on page 511) and the `commabeforerest` places a comma before the *post-note*, if present (e.g., in Example 16-5-1 on the next page and many others in this section).

In contrast to `natbib`, the `jurabib` package requires the use of specially designed \LaTeX style files. It expects a `\bibitem` command with a highly structured optional argument to pass all kinds of information back to the user-level citation commands (see page 488). These \LaTeX styles also implement a number of additional fields useful in conjunction with `jurabib`.

To show the particular features of `jurabib`, we again use our main sample database (Figure 15.1 on pages 382–383). If not explicitly documented otherwise, all examples in this section have the line

```
\newpage\bibliography{t1c}
```

implicitly appended at the end when processed.

The basic syntax

Like the `natbib` package, the `jurabib` package extends the standard \LaTeX citation command `\cite` with a second optional argument.

```
\cite[post-note]{key1,key2,...}  
\cite[annotator][post-note]{key1,...}
```

If two optional arguments are present, then the *post-note* argument moves to the second position, the same behavior found with the `natbib` syntax. In the default setup there is a big difference in that we do not have a *pre-note* argument but rather an *annotator* argument provided for a citation method used in legal works.¹ In that discipline, works often have an original author (under which the work is listed in the bibliography) as well as annotators who provide commentaries in the particular edition. These annotators are mentioned in the citation but not in the bibliography. Without further adjustments a citation lists only the author surnames (separated by slashes if there are several authors), followed by the *annotator* if present, followed

¹ See page 512 if you want it to be a *pre-note* instead.

by a possible *post-note*. If the `BIBTEX` entry contains a `shortauthor` field, then it is used instead of the surnames. If you only want to specify an *annotator*, use an empty *post-note*. By default, a title or short title is shown only if the author is cited with different works in the same document.

	<code>\usepackage{jurabib} \bibliographystyle{jurabib}</code>
Brox/Walker	<code>\cite{aschur}</code> <code>\\</code>
Brox/Walker, § 123	<code>\cite[\S\,123]{aschur}</code> <code>\\</code>
Otto Palandt/Heinrichs	<code>\cite[Heinrichs] [] {bgb}</code> <code>\\</code>
Otto Palandt/Heinrichs, § 26	<code>\cite[Heinrichs] [\S\,26]{bgb}</code>

As you see, there is no way to determine from the typeset result that “Walker” is a coauthor but “Heinrichs” is an annotator. To make this distinction immediately visible, jurabib offers a number of options implementing common citation styles. You can, for example, change the font used for the annotator or change the separator between author and annotator. Both of these changes have been specified in the first part of the next example. You can also move the annotator before the author, a solution shown in two variants in the second part of the example.

	<code>\usepackage{jurabib} \bibliographystyle{jurabib}</code>
	<code>\jurabibsetup{annotatorformat=italic,</code>
	<code>annotatorlastsep=divis}</code>
Brox/Walker	<code>\cite{aschur} \ \ \cite[Heinrichs]{\S,26}{bgb} \ \</code>
Otto Palandt– <i>Heinrichs</i> , § 26	<code>\jurabibsetup{annotatorfirstsep=comma}</code>
<i>Heinrichs</i> , Otto Palandt, § 26	<code>\cite[Heinrichs]{\S,26}{bgb} \ \</code>
	<code>\jurabibsetup{annotatorfirstsep=in,annotatorformat=normal}</code>
Heinrichs in: Otto Palandt, § 26	<code>\cite[Heinrichs]{\S,26}{bgb}</code>

Another way to clearly distinguish authors and annotators is to use the option `authorformat` with the value `and` (which replaces slashes with commas and “and”) the value `dynamic` (in which case different fonts are used depending on whether an *annotator* is present), or the value `year` (which moves the publication year directly after the author). The `authorformat` option can also be used to influence other aspects of the formatting of author names. Some examples are shown below. A complete list of allowed values is given in the package documentation. Note that if you use several values together (as done below), you need an additional set of braces to indicate to `jurabib` where the value list ends and the next option starts.

16-5-3 BROX and WALKER
 OTTO PALANDT/HEINRICHS, § 26

If the value `dynamic` is used, the annotator's name is set in italics, while the original author's name is set in the body font.¹ For works without an annotator, author

¹The fonts used can be customized by redefining the commands `\jbactualauthorfont` and `\jbactualauthorfontifannotator`.

names are set in italics. One can think of this style as labeling those people who have actually worked on the particular edition.

<i>Brox/Walker</i>	<code>\usepackage{jurabib} \bibliographystyle{jurabib}</code>	
Otto Palandt/ <i>Heinrichs</i> , § 26	<code>\jurabibsetup{authorformat=dynamic}</code>	
	<code>\cite{aschur} \ \cite[Heinrichs][\S\,26]{bgb} \par</code>	16-5-4

The values `and`, `dynamic`, and `year` can be combined, while `smallcaps` and `italic` override each other with the last specification winning:

<i>Brox and Walker</i> (2003)	<code>\usepackage{jurabib} \bibliographystyle{jurabib}</code>	
Otto Palandt (2003)/ <i>Heinrichs</i> , § 26	<code>\jurabibsetup{authorformat={and,smallcaps,year,italic}}</code>	
	<code>\cite{aschur} \ \cite[Heinrichs][\S\,26]{bgb} \par</code>	16-5-5

The information passed back by BibTeX is very detailed and structured into individual fields whose contents can be accessed using the `\citefield` command.

`\citefield[post-note]{field}{key1,key2,...}`

The *field* argument is one of the following fields from the BibTeX database entry referenced by the *key* argument: `author`, `shortauthor`, `title`, `shorttitle`, `url`, or `year`. It can also be `apy` (address-publisher-year combination).

Whether more than a single *key* is useful is questionable for most fields. Indeed, even with `\cite` multiple keys are seldom useful unless no optional arguments are present.

BROX, HANS/WALKER, WOLF-DIETRICH	<code>\usepackage{jurabib} \bibliographystyle{jurabib}</code>	
BSchuR, § 53	<code>\jurabibsetup{authorformat=smallcaps}</code>	
Reading, MA, USA: Addison-Wesley Long-	<code>\citefield{author}{aschur} \ \</code>	
man, 1997	<code>\citefield[\S\,53]{shorttitle}{bschur} \ \</code>	
Allgemeines Schuldrecht; Besonderes Schul-	<code>\citefield{apy}{LGC97} \ \</code>	
drecht	<code>\citefield{title}{aschur,bschur}</code>	16-5-6

If you are familiar with the German language, you will have noticed that the hyphenation of “Schul-drecht” is incorrect: it should have been “Schuld-recht”. How to achieve this hyphenation automatically is explained on page 524.

Citations with short and full titles

As mentioned earlier, by default jurabib does not include a title in the citation text. The exception occurs when there are several works cited by the same author so that a title is necessary to distinguish between them. This behavior can be changed in several ways, but first we have a look at the “title” that will be used in such cases.

If you compare the first two lines of the next example with the BibTeX database file listed in Figure 15.1 on pages 382–383, you see that the `shorttitle` field was used if available; otherwise, the `title` field was used. In fact, you get a warning from

jurabib for this adjustment: “shorttitle for aschur is missing - replacing with title”. A different approach is taken for entries of type `article` or `periodical`; there, a missing `shorttitle` is replaced by the journal name, volume number, and year of publication, which is why we got “TUGboat 10 [1989]”.

Brox/Walker: Allgemeines Schuldrecht

Brox/Walker: BSchuR

Knuth: The T_EXbook

Knuth: TUGboat 10 [1989]

```
\usepackage{jurabib} \bibliographystyle{jurabib}
```

```
\cite{aschur} \ \ \cite{bschur} \ \ [2pt]
```

```
\cite{Knuth-CT-a} \ \ \cite{Knuth:TB10-1-31}
```

16-5-7

The colon after the author names above is due to the `commabeforereset` default that we have applied to all examples in this section; see page 508.

```
\citetitle[post-note]{key1,key2,...} \citetitle[annotator][post-note]{key1,...}
\cite*[post-note]{key1,key2,...} \cite*[annotator][post-note]{key1,...}
```

To force the production of a title in the citation, you can use `\citetitle` instead of `\cite`. To leave out the title, you can use `\cite*`. You should, however, be aware that the latter command can easily lead to ambiguous citations, as shown in the next example:

Baumbach et al.: ZPO, Brox/Walker, and Brox/
Walker are three different books, or not?

```
\usepackage{jurabib} \bibliographystyle{jurabib}
```

```
\citetitle{zpo}, \cite*{aschur}, and
```

```
\cite*{bschur} are three different books, or not?
```

16-5-8

Also note that this meaning of `\cite*` is quite different from its use in `natbib` (where it denotes using a full list of authors). If you switch between both packages depending on the circumstances, it might be better to avoid it altogether.

```
\citetitleonly[post-note]{key}
```

It is also possible to refer to only the title, including a *post-note* if desired.

ZPO, § 13

```
\usepackage{jurabib} \bibliographystyle{jurabib}
```

```
\citetitleonly[\S\,13]{zpo}
```

16-5-9

To generate short-title citations by default, specify the option `titleformat` with the value `all`. Like `authorformat`, this option can take several values. We already know about `colonsep`, which we used as a default setting for all the examples. In the next example we overwrite it with `commasep` and print the titles in *italic*.

*Getting short-title
citations
automatically*

Brox/Walker, *Allgemeines Schuldrecht*, § 123

Brox/Walker, *BSchuR*

Otto Palandt/Heinrichs, *BGB*

Knuth, *TUGboat 10 [1989]*

```
\usepackage{jurabib} \bibliographystyle{jurabib}
```

```
\jurabibsetup{titleformat={all,commasep,italic}}
```

```
\cite[\S\,123]{aschur} \ \ \cite{bschur} \ \
```

```
\cite{Heinrichs} [] {bgb} \ \ \cite{Knuth:TB10-1-31}
```

16-5-10

```
\citetitlefortype{BibTeX-type-list} \citenotitlefortype{BibTeX-type-list}
```

Instead of citing all works with titles, you can select short-title citations based on a particular BibTeX type. For example,

```
\citetitlefortype{article,book>manual}
```

would reference these three types with the title and all other publication types without it, unless the author is cited with several works. Because such a list can grow quite large, you can alternatively select automatic title citations for all works (with `titleformat`) and then specify those types that should have no titles when referenced. This is done in the next example for the type `book`. Nevertheless, the book by Knuth is cited with its title, because we also cite an article by him.

```
Brox/Walker          \usepackage{jurabib} \bibliographystyle{jurabib}
Goossens/Rahtz       \jurabibsetup{titleformat=all} \citenotitlefortype{book}
Knuth: The TEXbook    \cite{bschur}      \ \ \cite{LWC99}      \ \
Knuth: TUGboat 10 [1989] \cite{Knuth-CT-a} \ \ \cite{Knuth:TB10-1-31}
```

16-5-11

Indexing citations automatically

The author names in citations can be entered in the index by using the option `authorformat` with the value `indexed`. By default, this is done only for citations inside the text; authors referred to only in the bibliography are not listed. This behavior can be changed by setting `\jbindexbib` in the preamble or in a configuration file. For formatting the index entries, `\jbauthorindexfont` is available. For example,

```
\renewcommand\jbauthorindexfont[1]{\textit{#1}}
```

means that the author names appear in italic in the index.

Instead of placing the author names in the main index, you can produce a separate author index by loading the index package (see Section 14.5.3) and then using a construction like

```
\usepackage{index}
\newindex{default}{idx}{ind}{Index}           % the main index
\newindex{authors}{adx}{and}{Index of Authors}
\renewcommand\jbindextype{authors}
```

in the preamble, and later `\printindex[authors]` to indicate where the author index should appear in the document.

No support is available for more elaborate indexes as required for some types of law books (e.g., “Table of Cases” or “Table of Statutes”). If this is required, you have to generate the index by different means.

Using natbib citation semantics

The optional *annotator* argument is useful only in legal studies. In other disciplines, it is more common to require a *pre-note* (e.g., “compare...”). To account for this, the

meanings of the optional arguments can be modified by loading the package with the option `see`.

`\cite[pre-note] [post-note] {key1,key2,...}` (with option `see`)

The `see` option replaces the default `annotator` optional argument with a *pre-note* argument in the case that two optional arguments are used. The `\cite` command then has the same syntax and semantics as it does with the `natbib` package.

(Goossens/Rahtz/Mittelbach)	<code>\usepackage[see,round]{jurabib}</code>
(Goossens/Rahtz/Mittelbach, chap. 2)	<code>\bibliographystyle{jurabib}</code>
(compare Goossens/Rahtz/Mittelbach)	<code>\cite[LGC97]{} \\\cite[chap.-2]{LGC97} \\\[3pt]</code>
(see Goossens/Rahtz/Mittelbach, chap. 2)	<code>\cite[compare]{}{LGC97}\\\cite[see][chap.-2]{LGC97}</code>

This work was cited as ...

When using a short-title system for citations (e.g., by setting `titleformat` to `all`), it can be helpful to present the reader with a mapping between the full entry and the short title. This is commonly done by displaying the short title in parentheses at the end of the corresponding entry in the bibliography. The `jurabib` package supports this convention with the option `howcited`. It can take a number of values that configure the mechanism in slightly different ways. For example, the value `all` instructs the package to add “how cited” information to all entries in the bibliography. Thus, if we add to Example 16-5-10 on page 511 the line `\jurabibsetup{howcited=all}`, then we get the following bibliography listing. Note that the short title is formatted in exactly the same way as it appears in the citation.

Brox, Hans/Walker, Wolf-Dietrich: Besonderes Schuldrecht. 27th edition. München, 2002 (cited: Brox/Walker, *BSchuR*)

Brox, Hans/Walker, Wolf-Dietrich: Allgemeines Schuldrecht. 29th edition. München, 2003 (cited: Brox/Walker, *Allgemeines Schuldrecht*)

Knuth, Donald E.: Typesetting Concrete Mathematics. TUGboat, 10 April 1989, Nr. 1, 31–36, ISSN 0896–3207 (cited: Knuth, *TUGboat* 10 [1989])

Palandt, Otto: Bürgerliches Gesetzbuch. 62th edition. München: Beck Juristischer Verlag, 2003 (cited: Otto Palandt, *BGB*)

However, it is usually not necessary to display for all entries how they are cited. For articles, the short-title citation is always “author name, journal, volume, and year”. If a work is cited with its full title (i.e., if there is no `shorttitle` field) or if only a single publication is cited for a certain author, then the reader will generally be able to identify the corresponding entry without any further help. To allow for such a restricted type of “back-references”, `jurabib` offers the values `compare`, `multiple`, and `normal`.

If you use `compare`, then a back-reference is created only if the entry has been referenced (prior to typesetting the bibliography), contains a `shorttitle` field, and

the `title` and `shorttitle` fields differ. With respect to Example 16-5-13 this means that only the first and last entries would show the back-references.

If you use `multiple` instead, then back-references are generated whenever an author is cited with several works except for citations of articles. In the above example, the first two entries would get back-references. If we also had a citation to `Knuth-CT-a`, then it would also show a back-reference, while Knuth's article in *TUGboat* would be still without one.

Both values can be used together. In that case back-references are added to entries for authors with several publications as well as to entries whose short titles differ from their main titles.

Finally, there is the value `normal` (it is also used if you specify the option without a value). This value works slightly differently from the others in that it needs support to be present in the `BibTeX` database. If it is used, an entry gets a back-reference if and only if the `BibTeX` field `howcited` is present. The field can have two kinds of values. If it has a value of "1", the back-reference lists exactly what is shown in the citation in text. With any other value, the actual contents of the `howcited` field are used for the back-reference, including any formatting directives contained therein.

The text surrounding the back-reference can be customized by redefining the commands `\howcitedprefix` and `\howcitedsuffix`. In addition, you can specify what should happen with entries that have been added via `\nocite` by changing `\bibnotcited` (empty by default). Because these commands may contain text that should differ depending on the main language of the document, they are redefined using a special mechanism (`\AddTo`) that is explained on page 524.

Full citations inside the text

While producing full ("verbose") citations inside the text with `natbib` requires a separate package and some initial preparation, this citation method is fully integrated in `jurabib`. The complete entry can be shown for one or more individual citations, for all citations, or automatically for only the first citation of a work. This citation method is

most often used in footnotes; see page 518 for information on how to automatically arrange footnote citations.

```
\fullcite[post-note]{key1,key2,...}
\fullcite[annotator][post-note]{key1,key2,...}
```

This command works like `\cite` but displays the full bibliographical data. The *annotator*, if present, is placed in front of the citation in the same way as if `annotatorfirstsep=in` had been specified.

Compare the next example with Example 16-6-1 from page 538. The value `citationreversed` arranges for the author name to appear with surname last (in the bibliography the surname comes first). Related values are `allreversed` (surname last in text and bibliography) and `firstnotreversed` (surname first for first author, last for all others in multiple-author works).

For details see Donald E. Knuth: Typesetting Concrete Mathematics. TUGboat, 10 April 1989, Nr. 1, ISSN 0896–3207. General information can be found in Donald E. Knuth: The TeXbook. Volume A, Computers and Typesetting. Reading, MA, USA: Addison-Wesley, 1986, ISBN 0–201–13447–0.

The `\cite` command automatically generates full citations if the `citefull` option is specified together with one of the following values: `all` (all references are full citations), `first` (first citation is full, subsequent ones are abbreviated), `chapter` (same as `first` but restarts with each chapter), and `section` (like `chapter` but restarts at the `\section` level). All settings imply `annotatorfirstsep=in`, as can be seen in the second citation in the example. If one of the above settings has been included in the configuration file and you want to turn it off for the current document, use the value `false`.

```
\nextciteshort{key1,key2,...} \nextcitefull{key1,key2,...}
\nextcitereset{key1,key2,...} \nextcitenotitle{key1,key2,...}
```

Sometimes it is not correct to make the first citation to a work be the full entry, such as in an abstract or preface. On the other hand, you may want to have a certain citation show the full entry again, even though it appeared earlier. For this purpose four commands are available that modify how individual citations are presented from the given point onward.¹

If you use `\nextciteshort`, all citations specified in the *key-list* are typeset as short-title citations from then on (e.g., lines A, B, D in the example). If you use `\nextcitereset`, the citations are (again) typeset in the normal way; thus, the next citation will be a full citation if there has not been one yet (lines C and F), and otherwise citations are set as short-title citations (line E). With `\nextcitefull`, you force full entries from then on (line G). With `\nextcitenotitle`, you get only the author name(s), even if it results in ambiguous citations.

16-5-18

If full citations are used within the main document, it is not absolutely necessary to assemble them in a bibliography or reference list. You may, for example, have

¹The command names seem to indicate that they change the “next” citation, but in fact they change all further citations until they are overwritten.

all citations inline and use a bibliography for suggested further reading or other secondary material.

```
\citeswithoutentry{key-list}
```

This declaration lists those keys that should not appear in the bibliography even though they are cited in the text. The *key-list* is a list of comma-separated keys without any white space. You can repeat this command as often as necessary. Think of it as the opposite of `\nocite`. Both commands are used in the next example:

This is explained in Brox, Hans/Walker, Wolf-Dietrich:
Allgemeines Schuldrecht. 29th edition. München, 2003.
As shown in Brox/Walker...

Selected further reading

\citeswithoutentry{aschur}
\jurabibsetup{citefull=first}

This is explained in \cite{aschur}.
\par As shown in \cite{aschur}\ldots
\nocite{zpo}
\bibliography{t1c}
```

16-5-19

While `\citeswithoutentry` prevents individual works from appearing in the bibliography, it is not possible to use it to suppress all entries, because you would get an empty list consisting of just the heading. If you want to omit the bibliography altogether, use `\nobibliography` in place of the usual `\bibliography` command. This command reads the `.bbl` file produced by `BibTeX` to enable citation references, but without producing a typeset result. You still need to specify `jurabib` as the `BibTeX` style and run `BibTeX` in the normal way.

*Suppressing the
bibliography
altogether*

Citations as footnotes or endnotes

All citation commands introduced so far have variants that generate footnote citations or, when used together with the `endnotes` package, generate endnotes. Simply prepend `foot` to the command name (e.g., `\footcite` instead of `\cite`, `\footcitetitle` instead of `\citetitle`, and so forth). This allows you to mix footnote and other citations freely, if needed.

The footnote citations produced by `jurabib` are ordinary footnotes, so you can influence their layout by loading the `footmisc` package, if desired.

```

16-5-20

Getting footnote
citations
automatically

If all your citations should be automatically typeset as footnotes, use the `super` option. In that case `jurabib` automatically chooses the `\foot..` variants, so `\cite` produces `\footcite`, and so forth. This is shown in the next example. There we also use `citefull=first` so that the first footnote looks like the one in the previous example (to save space we show only the second page, where due to the ridiculously small height of the example page the last line of that footnote is carried over). The other two citations are then automatically shortened, with the third being shortened even further because of the `ibidem` option (explained on the next page).

We also use the option `lookat`, which is responsible for the back-reference to the earlier note containing the full citation. This option is allowed only if you simultaneously use the `citefull` option and have all your initial citations in footnotes, because it requires a “number” to refer to.

You have to be careful to use a footnote style that produces unique numbers. If footnotes are numbered by chapter or by page, for example, then such references are ambiguous. This problem can be solved by loading the `varioref` package, in which case these back-references also show page numbers. If `varioref` is loaded for other reasons and you do not want page references in this place, use `\jbignorevarioref` to suppress them. If footnotes are numbered by chapter, then an alternative solution is to use the `\labelformat` declaration to indicate to which chapter the footnote belongs:

```
\labelformat{footnote}{\thechapter--#1}
```

The `lookat` option is particularly useful in combination with the command `\nobibliography` so that all your bibliographical information is placed in footnotes without a summary bibliography.

Also discussed is generating PDF² and HTML.³

43311–7.

²Goossens/Rahtz (as in n. 1), chap. 2.

³Ibid., chap. 3–4.

```
\usepackage{jurabib} \bibliographystyle{jurabib}
\jurabibsetup{super,citefull=first,ibidem,lookat}
\ldots to use \LaTeX{} on the web.\cite{LWC99}
\newpage % Next page shown on the left:
Also discussed is generating PDF\cite[chap.~2]
{LWC99} and HTML.\cite[chap.~3--4]{LWC99}
```

16-5-21

It is possible to customize the appearance of the back-references by using the commands `\lookatprefix` and `\lookatsuffix`. Both are language dependent, which is the reason for using the `\AddTo` declaration (see page 524). The example sets up a style commonly seen in law citations [22].

Also discussed is generating PDF² and HTML.³

43311–7.

Ibidem — In the same place

In some disciplines it is customary to use the Latin word “*ibidem*” (abbreviated as “*ibid.*” or “*ib.*”) if you repeat a reference to the immediately preceding citation. The `jurabib` package supports this convention in several variants if the option `ibidem` is specified. This option must be used with footnote-style citations (e.g., when using `\footcite` or with the option `super` activated).

If `ibidem` is used without a value (which is the same as using it with the value `strict`), then the following happens: if a citation refers to the same publication as the immediately preceding citation on the *current* page, then it is replaced by “*Ibid.*”, if necessary keeping a *post-note*. You can see this situation in the next example: the first citation is a short-title citation; the second citation is identical, so we get “*Ibid.*” with the *post-note* dropped; and the third and fourth citations refer to different parts of the same publication, so we get the *post-note* as well. The fifth citation refers to a different publication by the same authors, so another short-title citation is produced. The sixth citation refers to the same publication, but the short-title citation is repeated because it is on a new page. The seventh and eighth citations are again to the other publication, so we get first a short-title citation and then “*Ibid.*” with a *post-note*.

```

16-5-24

¹jurabib is currently not compatible with the newer enotez.

If you typeset your document with the class option `twoside`, then you can use the value `strictdoublepage`. It means that “Ibid.” is also used across page boundaries as long as the preceding citation is still visible (i.e., on the same spread). Repeating Example 16-5-24 with this setting changes the sixth citation to “Ibid., §3”.

The `ibidem` option usually generates a lot of very short footnotes, so it might be economical to use it together with the `para` option of `footmisc`. We also add the `perpage` option so that the footnote numbers remain small. Note, however, that this makes it impossible to use the `lookat` option because the footnote numbers are no longer unique.

<p>Some¹ legal^{2,3} text^{4,5} with commentaries.</p> <hr/> <p>¹ Brox/Walker: BSchuR, § 7. ² Ibid. ³ Ibid., § 16. ⁴ Ibid., § 7. ⁵ Brox/Walker: Allgemeines Schuldrecht.</p>	<p>And^{1,2} several more.³</p> <hr/> <p>¹ Ibid., § 3. ² Brox/Walker: BSchuR. ³ Ibid., § 15.</p>	<pre>\usepackage[para,multiple,perpage]{footmisc} \usepackage{jurabib} \bibliographystyle{jurabib} \jurabibsetup{super,ibidem=strictdoublepage} Some \cite[\S,7]{bschur} legal \cite[\S,7]{bschur} \cite[\S,16]{bschur} text \cite[\S,7]{bschur} \cite{aschur} with commentaries. \newpage And \cite[\S,3]{aschur} \cite{bschur} several more. \cite[\S,15]{bschur}</pre>	16-5-25
--	--	---	---------

It is even possible to ignore all page boundaries by using the `nostrict` value. The reader might find it difficult to decipher the references, however, because “Ibid.” and the citation to which it refers may be moved arbitrarily far apart. If necessary, you can disable the `ibidem` mechanism for the next citation by preceding it with `\noibidem`.

<p>A page without a citation.</p>	<p>This page has references.² Maybe better like this?³</p> <hr/> <p>²Ibid. ³Brox/Walker.</p>	<pre>\usepackage{jurabib} \bibliographystyle{jurabib} \jurabibsetup{super,ibidem=nostrict} \ldots \fullcite{bschur} \ldots \newpage % page above not shown on the left A page without a citation. \newpage This page has references.\cite{bschur} Maybe better like this? \noibidem\cite{bschur}</pre>	16-5-26
-----------------------------------	--	---	---------

The use of “Ibid.” without any further qualification allows you to reference just the immediately preceding citation. Thus, if citations are frequently mixed, the mechanism inserts short-title references most of the time. This situation changes if you use the `ibidem` option with the value `name` (which automatically implies `citefull=first`). In that case “Ibid.” is used with the full name of the author, thus allowing a reference to an earlier — not directly preceding — citation. If only the surnames of the authors are required, add the `authorformat` option with the value `reducedifibidem`. Its effect is seen in the next example, where citations to `bschur` and `zpo` alternate. A variant is to always use the name and short title except for the first citation of a publication; this format can be requested with the value `name&title`.

If the same author is cited with more than one publication, then using the `ibidem` option with the `name` value is likely to produce ambiguous references. For those citations the `jurabib` package automatically switches to the `name&title&auto` method described below.

A¹ legal^{2,3} text^{4,5} with⁶ commentaries.

with \cite[\S\,3]{zpo} commentaries.
```

If `name&title&auto` was selected (either implicitly or explicitly), then the following happens: the first citation of a publication automatically displays the full entry (citation 5 in the next example). In the case of repeated citations to unambiguous works only the names of the authors are shown (citation 8). For ambiguous citations this is done only for immediately following citations (citation 4). However, if there are intervening citations, then the names and short titles are shown (citations 3, 6, and 7).

Another convention in certain disciplines is to replace the author's name with the Latin word "Idem" (meaning "the same") if the author of successive citations is identical. This is catered for by the option `idem`, which accepts the values `strict`, `strictdoublepage`, and `nostrict` with the same semantics as used with the `ibidem` option. Both options can be combined as shown in Example 16-5-29 on the following page. Due to the values used, we get different citations: some use "Idem, *ibid.*"; after the page break "Idem" is suppressed, because of the option `strict`; and in the last three citations it is used again (even with the full citation) because they all refer to different publications of Donald Knuth.

16-5-29

You have to ask yourself whether this type of citation is actually helpful to your readers. Butcher [28], for example, argues against it. Of course, you may not have a choice in the matter — it might be required. You should, however, note that two citations in the previous example are actually wrong: van Leunen is a female author, so the correct Latin form would be “Eadem” and not “Idem” (though some style manuals do not make that distinction). If necessary, *jurabib* offers possibilities for adjusting your citations even on that level of detail; see page 525.

There is another convention related to recurring citations, though it is becoming less common: to signal that a citation refers to an earlier reference, it is flagged with *op. cit.* (*opere citato*, “in the work cited”). This practice is supported with the option *opcit*. The citation should be “close by” so that the reader has a chance to find it. For this reason *jurabib* offers the values *chapter* and *section* in analogy to the *citefull* option.

\cite[p.~22]{Knuth-CT-a} and
\cite{GNUmake} some more text
\cite{Knuth-CT-a}\cite{GNUmake}
```

16-5-30

In law citations [22], it is common to use the word “*supra*” to indicate a reference to a previous citation. This can be accomplished by changing the *\opcit* command, which holds the generated string, as follows:

```
\renewcommand\opcit{\textit{supra}}
```

Alternatively, you can use the method shown in Example 16-5-22 on page 518.

Cross-referencing citations

`BIBTEX` supports the notion of cross-references between bibliographical entries via the `crossref` field. For example, an entry of type `inproceedings` can reference the proceedings issue in which it appears. Depending on the number of references to such an issue, `BIBTEX` then decides whether to produce a separate entry for the issue or to include information about it in each `inproceedings` entry. See Section 15.3.7 for details.

If `BIBTEX` decides to produce separate entries for the cross-referenced citations, a question arises about what should happen if they are referenced in a `\fullcite` or `\footfullcite` command in the text. To handle this situation `jurabib` offers three values applicable to the `crossref` option: with the value `normal` (the default), cross-references are typeset as an author/editor, title combination (or `shortauthor`, `shorttitle` if available); with the value `short`, only the author or editor is used as long as there are no ambiguities; and with the value `long`, cross-references are listed in full. The default behavior is shown below (where the editors and the short title were selected by `jurabib`).

Mittelbach, Frank/Rowley, Chris: The Pursuit of Quality: How can Automated Typesetting achieve the Highest Standards of Craft Typography? In Vanoirbeek/Coray: EP92

Southall, Richard: Presentation Rules and Rules of Composition in the Formatting of Complex Text. In Vanoirbeek/Coray: EP92

Mittelbach/Rowley

```
\usepackage{jurabib}
\jurabibsetup{citefull=first,
              crossref=normal}
\bibliographystyle{jurabib}

\cite{MR-PQ}      \par
\cite{Southall}   \par
\cite{MR-PQ}
```

16-5-31

You can combine any of the three values with the value `dynamic`, in which case a cross-reference is given in a longer form when cited the first time and in the shorter form on all later occasions. Here we combine it with the value `long` so that we get a full citation to Vanoirbeek/Coray in the first citation and a short title citation in the second.

              authorformat=
                citationreversed,
              crossref={dynamic,long}}
\bibliographystyle{jurabib}

\cite{MR-PQ}      \par
\cite{Southall}
```

16-5-32

Author-date citation support

As mentioned earlier, `jurabib` supports the commands `\citeta` and `\citep` as introduced by `natbib`. It also offers `\citealt`, `\citealp`, `\citeauthor`, `\citeyear`, and `\citeyearpar`. Those forms for which it makes sense are also available as

to this storage place.¹ The first argument is either `\bibsall`, in which case *code* is used for all languages, or `\bibs⟨language⟩` (e.g., `\bibsgerman`), in which case *code* is applied for that particular *language*.² In Example 16-5-14 on page 514 and Example 16-5-22 on page 518 we used `\AddTo` to change the presentation of back-references for all languages, by adding the redefinitions to `\bibsall`. Below we shorten the “Ibid.” string when typesetting in the English language. The default for other languages is left unchanged in this case.

```

16-5-35

While certain strings — calling an editor (`\editorname`) “(Hrsg.)”, for example — should clearly be consistent throughout the whole bibliography, certain other aspects — most importantly, hyphenation — depend on the language used in the actual entry. For instance, a book with a German title should be hyphenated with German hyphenation patterns, regardless of the main language of the document. This is supported by `jurabib` through an extra field (`language`) in the B_BT_EX database file. If that field is specified in a given entry, then `jurabib` assumes that the title should be set in that particular language. Thus, if hyphenation patterns for that language are available (i.e., loaded in the format), they are applied. For instance, if we repeat the last part of Example 16-5-6 from page 510 with `babel` loaded, we get the correct hyphenation as shown below:

Allgemeines Schuldrecht; Besonderes Schuldrecht

```
\usepackage[ngerman,english]{babel}
\usepackage{jurabib} \bibliographystyle{jurabib}
\citefield{title}{aschur,bschur}
```

16-5-36

Distinguishing the author’s gender

Earlier, we mentioned that the female form of “Idem” is “Eadem”. In the German language, we have “Derselbe” (male), “Dieselbe” (female), “Dasselbe” (neuter), and “Dieselben” (plural). To be able to distinguish the gender of the author, `jurabib` offers the B_BT_EX field `gender`, which takes a two-letter abbreviation for the gender as its value.

Possible values and the commands that contain the “Idem” strings, if specified, are given in Table 16.2 on the following page. The commands with an uppercase letter in

¹The `babel` package uses a similar mechanism with the `\addto` declaration.

²Unfortunately, `jurabib` does not use exactly the same concept as `babel`. If you specify `ngerman` with `babel` to get German with new hyphenation patterns, then this is mapped to `german`, so you have to update `\bibsgerman`. If you use any of the dialects (e.g., `austrian`), then `jurabib` does not recognize those and uses `english` after issuing a warning. In that case use `\bibsall` for changing definitions.

gender	Meaning	In Citation	In Bibliography
sf	single female	<code>\idemSfname, \idemsfname</code>	<code>\bibidemSfname, \bibidemsfname</code>
sm	single male	<code>\idemSmname, \idemsname</code>	<code>\bibidemSmname, \bibidemsname</code>
pf	plural female	<code>\idemPfname, \idempfname</code>	<code>\bibidemPfname, \bibidempfname</code>
pm	plural male	<code>\idemPmname, \idempmname</code>	<code>\bibidemPmname, \bibidempmname</code>
sn	single neuter	<code>\idemSnname, \idemsname</code>	<code>\bibidemSnname, \bibidemsname</code>
pn	plural neuter	<code>\idemPnname, \idempnname</code>	<code>\bibidemPnname, \bibidempnname</code>

Table 16.2: Gender specification in jurabib

their name are used at the beginning of a sentence, the others in mid-sentence. Those starting with `\bibidem..` are used in the bibliography if the option `bibformat` with the value `ibidem` is specified. Given that the feature is computing intensive, it is not activated by default but has to be requested explicitly. Thus, to change to “Eadem” in the case of female authors, we have to specify values for `\idemSfname` and `\idemsfname` and use the option `lookforgender`.

16-5-37

Customizing the in-text citation layout further

Most of the author and title formatting is handled by the options `authorformat` and `titleformat`, which were discussed earlier. There also exist a few more options and commands that we have not mentioned so far.

If the whole citation should be surrounded by parentheses, simply specify the option `round` or `square`.

To place information about the edition as a superscript after the short title, specify the option `superscriptedition`. With a value of `all` this is applied to all short-title citations, with the value `commented` applying only to publications of type `commented`, and with the value `multiple` applying only to publications that are cited with several different editions. The last two options are primarily intended for juridical works.

[Baumbach et al.: ZPO⁵⁹]

[Brox/Walker²⁷, § 3]

[Otto Palandt/Heinrichs⁶²]

```
\usepackage{jurabib} \bibliographystyle{jurabib}
\jurabibsetup{square,superscriptedition={all}}
\citetitle{zpo}\ \cite{S\,3}{bschur}\ \cite{Heinrichs}[]\bgb}
```

16-5-38

Alternatively, you can explicitly specify in the BibTeX database for each entry whether the edition should be shown as a superscript by setting the special field `ssedition` to the value 1 and by using the option `superscriptedition` with the value switch.

By specifying `authorformat=and` you get author names separated by commas and “and” (actually by `\andname`, a command that has different values in different languages). You cannot have the second and third author names separated by “, and” in this way. For adjustments on such a fine level, you can redefine `\jbbtasep` (between two authors separation), `\jbbfsasep` (between first and second authors separation), and `\jbbstasep` (between second and third authors separation).¹

16-5-39

```

\usepackage[round]{jurabib}
\renewcommand\jbbtasep{ and } \renewcommand\jbbfsasep{, }
\renewcommand\jbbstasep{, and } \bibliographystyle{jurabib}
(Brox and Walker)
(Goossens, Rahtz, and Mittelbach) \cite{aschur} \ \ \cite{LGC97}

```

You may also want to manually specify the fonts used for the author names and the short title, instead of relying on the possibilities offered by the supplied options. For this you have `\jbauthorfont`, `\jbannotatorfont`, `\jbactualauthorfont`, `\jbauthorfontifannotator`, and `\jbttitlefont` at your disposal, all of which are commands with one argument.

Customizing the bibliography layout

The formatting of the bibliography in standard L^AT_EX or with natbib is largely controlled by the used BibTeX style file or, if the bibliography entries are manually produced, by the formatting directives entered by the user. For example, a citation to the entry `Knuth-CT-a` from our sample database would be formatted by natbib's `plainnat` as follows:

```

Donald-E. Knuth.
\newblock {\em The {\TeX}book}, volume-A of {\em Computers and Typesetting}.
\newblock Ad{\-d}i{\-s}on-Wes{\-l}ey, Reading, MA, USA, 1986.

```

This means that formatting decisions, such as using emphasis for the title of the book and the series, and the presentation of the “volume” field, have all been made by the BibTeX style file.

In contrast, the BibTeX styles that come with the jurabib package use a drastically different approach: their output is highly structured, consisting of a large number of L^AT_EX commands, so that the final formatting (as well as the order of elements to some extent) can still be tweaked on the L^AT_EX level. In fact, they have to be adjusted on that level if you are not satisfied with the formatting produced from their default

¹No other possibilities are needed, because jurabib always uses “et al.” whenever there are four or more authors.

definitions. For example, the same citation as above processed with the `jurabib` \LaTeX style results in the following entry:

```
\jbbibargs {\bibnf {Knuth} {Donald-E.} {D.-E.} {} {}} {Donald-E. Knuth} {au}
{\bibtfnt {The {\TeX}book}\bibatsep\ \volumeformat {A} Computers and
Typesetting\bibatsep\ \apyformat {Reading, MA, USA\bpubaddr {}
Ad{\-d}i{\-s}on-Wes{\-l}ey\bibbdsep {} 1986} \jbPages{ix + 483}\jbisbn
{0--201--13447--0}} {\bibhowcited} \jbdoitem \bibAnnoteFile {Knuth-CT-a}
```

Most of the above commands are further structured. The `\bibnf` command takes five arguments (the different parts of the author's name) and, depending on which are nonempty, passes them on to commands like `\jbnfIndNoVonNoJr` (name without “von” and “Junior” parts) for further processing. Consequently, it is possible to interact with this process at many levels so that all kinds of requirements can be catered for, although this somewhat complicates the customization of the layout. For this reason we restrict ourselves to showing just the most important customization possibilities. For further control strategies, consult the package documentation.

In the default setup, the formatting of the bibliography is fairly independent of that used for the citations. If you specify `authorformat=italic`, author names are typeset in italics in the text, but there is no change in the bibliography. The easiest way to change that is to use the option `biblikecite`; then formatting decisions for the citations are also used in the bibliography as far as possible. If that is not desired or not sufficient, explicit formatting directives are available; they are discussed below.

The fonts used in a bibliographical entry are controlled by the following set of commands: `\biblnfont` and `\bibfnfont` for formatting the last and first names of the author, and `\bibelntfont` and `\bibefnfont` for the last and first names of the editor, if present. The command `\bibtfnt` is used for titles of books, `\bibbtfont` for titles of essays (i.e., entries involving a \LaTeX `booktitle` field), and `\bibjtfont` for titles, or rather names, of journals. The font for article titles within such a journal is customized with `\bibapifont`. The commands all receive the text they act upon as an argument, so any redefinition must also use an argument or `\text.. font` commands as shown in the next example (picking the argument up implicitly):

KNUTH, DONALD E.: The \TeX book. Volume A, Computers and Typesetting. Reading, MA, USA: Addison-Wesley, 1986, ix + 483, ISBN 0-201-13447-0	<code>\usepackage{jurabib}</code> <code>\bibliographystyle{jurabib}</code> <code>\renewcommand\biblnfont{\MakeUppercase}</code> <code>\renewcommand\bibfnfont{\textsc}</code> <code>\renewcommand\bibtfont {\textsf}</code>
KNUTH, DONALD E.: “ <i>Typesetting Concrete Mathematics</i> ”. TUGboat, 10 April 1989, Nr. 1, 31–36, ISSN 0896-3207	<code>\renewcommand\bibapifont[1]{\textit{‘‘#1’’}}</code> <code>\nocite{Knuth-CT-a,Knuth:TB10-1-31}</code> <code>\bibliography{t1c}</code>

16-5-40

The punctuation separating different parts in the entry can be customized by another set of commands: `\bibansep` sets the punctuation and space after the author name, `\bibeansp` does the same after the editor name, `\bibatsep` produces punctuation after the title (the space is already supplied!), and `\bibbdsep` is the

punctuation *before* the date. With `\bibjtsep` the journal title separation is set. There are similar commands for adjusting other parts.¹ In the next example we use these commands to remove the default colon after the author's name and then typeset a semicolon after the title, no comma before the year, and the word “in” before the journal name. We also use the `dotafter` option with the value `bibentry` to add a final period after each entry.

Vanoirbeek, Christine/Coray, Giovanni, editors EP92—Proceedings of Electronic Publishing, '92; Cambridge: Cambridge University Press 1992.

```
\usepackage[dotafter=bibentry]
{jurabib}
\bibliographystyle{jurabib}
\renewcommand\bibtsep{in }
\renewcommand\bibansep{ }
\renewcommand\bibatsep{;}
\renewcommand\bibbdsep{}
\nocite{Knuth:TB10-1-31,MR-PQ}
\bibliography{t1c}
```

16-5-41

We already saw that the separation between different author names in a citation can be adjusted by means of the `authorformat` option and various values. However, except for the value `allreversed`, this has no effect on the entries in the bibliography. To modify the formatting there, you have to redefine the commands `\bibbtasep`, `\bibbfsasep`, and `\bibbstasep`. The naming convention is the same as for the corresponding citation commands. A similar set of commands, `\bibbtasep`, `\bibbfsasep`, and `\bibbstasep`, is available to specify the separation between editor names in an entry.

\renewcommand\bibbfsasep{, }
\renewcommand\bibbstasep{, and }
\nocite{aschur,LGC97}
\bibliography{t1c}
```

16-5-42

The main option for influencing the general layout of the bibliography list is `bibformat`, which can take a number of values as its value. If you specify the value `nohang`, then the default indentation (of 2.5em) for the second and subsequent lines of a bibliographical entry is suppressed. Alternatively, you can explicitly set the indentation by changing the dimension parameter `\jbbibhang`, as in the next example. There we also use the values `compress` (using less space around entries) and `raggedright` (typesetting entries unjustified). For improved quality, especially when typesetting to a small measure, you may want to load the package `ragged2e`.

*Adjusting the
general layout of the
bibliography*

¹This area of `jurabib` is somewhat inconsistent in its naming conventions and command behavior.

Note the use of the `newcommands` option to overload the standard `\raggedright` (as used by `jurabib`) with `\RaggedRight`.

    {jurabib}
\bibliographystyle{jurunsrt}
\setlength\jbbibhang{1pc}
\nocite{aschur,zpo,bschur}
\bibliography{t1c}
```

16-5-43

If you use the value `tabular`, then the bibliography is set in a two-column table with the left column containing the author(s) and the right column the remainder of the entry. By default, the first column is one-third of `\textwidth`, and both columns are set ragged. The defaults can be changed by redefining a number of commands, as shown in the next example. The width of the right column is specified by

```
\renewcommand\bibrightrightcolumn{\textwidth-\bibleftcolumn-\bibcolumnsep}
```

Normally it is enough to change `\bibleftcolumn` and/or `\bibcolumnsep`. The `calc` package is automatically loaded by `jurabib`, so we can make use of it when specifying dimensions.

16-5-44

If you use the value `numbered`, the bibliography is numbered even though the actual citations in the text use the author-date or short-title scheme. Currently, it is impossible to refer to those numbers.

Some publishers' house styles omit the author's name (or replace it by a dash or other character) if that author is cited with several works. This is supported through the value `ibidem`, which by default generates "Idem" or, more precisely, the result from executing `\bibidemSmname`. To get a (predefined) rule instead, use `\jbuseidemhrule`. If you want something else, redefine `\bibauthormultiple`. Both possibilities are shown in the next example. The `jurabib` package automatically detects if an entry appears on the top of a page and uses the author name in that case.

Because of this mechanism, it may take several (extra) L^AT_EX runs before the document compiles without “Rerun to get...”

\jurabibsetup[bibformat=ibidemalt]
\bibliographystyle{jurabib}
\nocite{aschur,bschur,zpo,bgb}
\bibliography{t1c}
```

16-5-46

If you want to produce an annotated bibliography, use the option `annotate`. If the current BibT_EX entry has an `annotate` field, it is typeset after the entry using `\jbannoteformat` to format it (the default is to typeset it in `\small`). If there is no `annotate` field, then `jurabib` searches for a file with the extension `.tex` and the key of the entry as its base name. If this file exists, its contents are used as the annotation text.

*Annotated
bibliographies*

Knuth, Donald E.: The T_EXbook. Volume A, Computers and Typesetting. Reading, MA, USA: Addison-Wesley, 1986, ix + 483, ISBN 0–201–13447–0

The authoritative user manual on the program T_EX by its creator.

```
\begin{filecontents}{Knuth-CT-a.tex}
The authoritative user manual on the program \TeX{}
by its creator.
\end{filecontents}
\usepackage[annotate]{jurabib}\bibliographystyle{jurabib}
\renewcommand\jbannoteformat[1]
{{\footnotesize\begin{quote}#1\end{quote}}}}
\nocite{Knuth-CT-a}
\bibliography{t1c}
```

16-5-47

Because it is a nuisance to have many files (one for each annotation) cluttering your current directory, `jurabib` offers a search path declaration in analogy to the `\graphicspath` command provided by the `graphics` package. Thus, after

```
\bibAnnotePath{./books}{./articles}}
```

annotation files are searched for in the subdirectories `books` and `articles` of the current directory.

Using external configuration files

Customization of `jurabib` is possible on two levels: by specifying options or, for finer control, by redefining certain declarations or executing commands. In the previous sections we have already encountered a number of package options together with the values they accept, but they represented less than a third of what is available. In the default configuration file `jurabib.cfg`, you find a `\jurabibsetup` declaration listing *all* options together with all their values—nearly 100 possibilities in total. They are all commented out so that you can produce your own configuration file by copying the default one and uncommenting those options that you want to execute normally. If you save this configuration in a file with extension `.cfg`, you can load it instead of the default configuration by using the `config` option. For example,

```
\usepackage[config=law]{jurabib}
```

loads the option file `law.cfg`, which should contain a `\jurabibsetup` declaration and possibly some additional customization commands. For example, such a file might contain

```
\jurabibsetup{lookat,opcit,commabeforerest,titleformat=colonsep}
\renewcommand\opcit{\textit{supra}}
```

and perhaps some other initializations to implement citations for juridical publications. As mentioned earlier, such defaults stored in a file can be overwritten by using additional options during loading or with a `\jurabibsetup` declaration in the preamble.

B_{ib}T_EX styles for `jurabib`

The `jurabib` package is distributed together with four B_{ib}T_EX style files: `jurabib`, `jureco`, `jurunsrt`, and `jox`. They differ only in minor details: `jureco` produces a slightly more compact bibliography, leaving out some data, while `jurunsrt` is the same as `jurabib` without sorting so that the references appear in order of their citation in the document. The `jox` style produces references in “Oxford style”. Because `jurabib` requires very specially formatted `\bibitem` commands, the above styles are currently the only ones that can be used together with the package.

All four styles provide several B_{ib}T_EX entries as well as a number of additional fields for existing entries. Having additional fields in a B_{ib}T_EX database is usually

not a problem, because `BibTeX` ignores any field it does not know about. Thus, such a database can be used with other `BibTeX` styles that do not provide these fields. Additional entries are slightly different, because using them means that you have to load `jurabib` to be able to refer to them.

The additional entries are `www` for citing a URL, `periodical` for periodicals that are not cited by year but by volume number, and `commented` for commentaries in juridical works. *Additional BibTeX types*

The standard `BibTeX` fields are described in Tables 15.3/4 on pages 388–389. The following additional fields are available when using one of the `jurabib` `BibTeX` styles: *Additional BibTeX fields*

`annote` An annotation that is typeset if `jurabib` is used with the option `annote`; see page 531 for details.

`booktitleaddon` Extra information to be typeset after a `booktitle` text of a collection.

`dissyear` Year of a dissertation, habilitation, or other source if that work is also being published as a book (perhaps with a different year).

`editortype` Position of the person mentioned in the `editor` field (if not really an “editor”).

`flanguage` Foreign language, in the case of a translated work.

`founder` In juridical works, the original founder of a publication (in contrast to the editor). The name is shown followed by the replacement text of `\foundername`, which defaults to “`_ (Begr.)`”.

`gender` Gender of the author or authors. The `jurabib` package uses this information to select the right kind of words for “Idem” in the current language; see page 525.

`howcited` Text to use for back-reference information, or 1 to indicate that a normal back-reference should be generated. This field is evaluated by the option `howcited` if used together with the value `normal`; see page 513.

`oaddress/opublisher/oyear` Information about the first edition of a work.

`shortauthor` Text to use as the author information in a short-title citation. By default, `jurabib` automatically selects the last name (or names) from the author or editor field.

`shorttitle` Text to use as the title information in a short-title citation. If it is not specified, the whole title is used.

`sortkey` String to be used for sorting in unusual situations. To sort “von Bismarck, Otto” under B, you can use `sortkey="Bismarck, Otto von"`.

`ssedition` Flag to indicate that this entry should be typeset with the edition shown as a superscript. It requires the use of the `superscriptedition` option together with the value `switch`; see page 526.

`titleaddon` Extra information to be placed after a title but not used, for example, when generating a short title.

totalpages Total number of pages in a publication. If present, it is shown followed by the replacement text of the command `\bibtotalpagesname`, which is language dependent.

translator Translator of the publication.

updated Date of the last update in a loose-leaf edition or a similar work. The field is available only for the `BIBTEX` type `commented`. By default, “last update *date*” is generated. This can be customized through the commands `\updatename` and `\updatesep`.

urldate Date when a URL was known to be current. By default, `jurabib` produces the string “visited on *date*” when this field is used. It can be changed by redefining the command `\urldatecomment`.

url A URL related to the current publication. In the case of the entry type `www`, it is required; otherwise, it is optional.

volumetitle A volume title that follows the volume number in the presentation. This field is available for the types `book`, `commented`, `incollection`, and `inbook`.

16.5.2 biblatex’s approach to author-title references

The `biblatex` package ships with various author-title styles. The documentation includes examples showing the output and documenting style-specific options. More styles are provided by external packages. Remember that styles are loaded with the package option `style` and that commands of the `natbib` package are emulated if you use the option `natbib`.

In this section we discuss styles that are meant to be used together with a bibliography; the special case of verbose citations follows in the next section.

The styles provided together with the `biblatex` package mainly differ in the way they compress citation lists and handle recurrent authors, titles, and page numbers in repeated citations. The next example exhibits the `authortitle` style. It does not try to save space and repeats author and title in follow-up citations. In the `EP92` entry it uses the `shorttitle` over the `title` field if it exists and falls back to the editor because no author exists.

Vanoirbeek and Coray (*EP92*)

Knuth (“Typesetting Concrete Mathematics”),
Leunen (*A handbook for scholars*), and Knuth
(*The T_EXbook*)

(Knuth, “Typesetting Concrete Mathematics”;
Knuth, *The T_EXbook*)

Knuth (*The T_EXbook*)...Knuth (*The T_EXbook*)

```
\usepackage[style=authortitle]{biblatex}
\addbibresource{tlc.bib}
\textcite{EP92}\
\textcite{Knuth:TB10-1-31,vLeunen:92,Knuth-CT-a}\
\parencite{Knuth:TB10-1-31,Knuth-CT-a}\
\textcite{Knuth-CT-a}\ldots \textcite{Knuth-CT-a}
```

16-5-48

Compare this with the output of the style `authortitle-ticomp`: this style activates the three features “terse”, “ibid”, and “compress”: “terse” prints the title only if the bibliography contains more than one work by the respective author/editor;

“ibid” replaces repeated citations by the abbreviation “ibidem” unless the citation is the first one on the current page, and “compress” sorts and compresses the list of citations that share the same author. By choosing the style `authortitle-terse` or `authortitle-icom` instead, it is possible to activate only a subset of the features.

<div style="border: 1px solid black; padding: 2px; display: inline-block;">16-5-49</div>	Vanoirbeek and Coray Knuth (<i>The T_EXbook</i> , “Typesetting Concrete Mathematics”) and Leunen (Knuth, <i>The T_EXbook</i> , “Typesetting Concrete Mathematics”) Knuth (<i>The T_EXbook</i>)... Knuth (ibid.)	<pre>\usepackage[style=authortitle-ticomp]{biblatex} \addbibresource{tlc.bib} \textcite{EP92}\ \textcite{Knuth:TB10-1-31,vLeunen:92,Knuth-CT-a}\ \parencite{Knuth:TB10-1-31,Knuth-CT-a}\ \textcite{Knuth-CT-a}\ldots \textcite{Knuth-CT-a}</pre>
--	---	--

When a reference contains a shorthand field, it is used instead of the title. A list of shorthands can then be printed with the `\printbiblist` command. We use the `csquotes` package to format the quotation:

<div style="border: 1px solid black; padding: 2px; display: inline-block;">16-5-50</div>	<p>“Handle so, daß die Maxime deines Willens jederzeit zugleich als Prinzip einer allgemeinen Gesetzgebung gelten könne.” (KpV)</p> <p>Abbreviations</p> <p>KpV Immanuel Kant. “Kritik der praktischen Vernunft”. In: <i>Kants Werke. Akademie Textausgabe</i>. Vol. 5: <i>Kritik der praktischen Vernunft. Kritik der Urtheilskraft</i>. Berlin: Walter de Gruyter, 1968, pp. 1–163.</p>	<pre>\usepackage[style=authortitle]{biblatex} \usepackage{csquotes} \SetCiteCommand{\parencite} \addbibresource{tlc.bib} \hyphenation{Ur-theils-kraft} \textcquote{kant:kpV}[.]{Handle so, daß die Maxime deines Willens jederzeit zugleich als Prinzip einer allgemeinen Gesetzgebung gelten könne} \printbiblist{shorthand}</pre>
--	--	---

It is possible to print only the author with the command `\citeauthor` (strictly speaking, `\citeauthor` prints the “labelname list”, which may be the author, editor, or translator). `\citetitle` prints the title or the shorttitle (but not a shorthand). `\cite*` prints the nonauthor part of the citation.¹ Note that this meaning of `\cite*` is quite different from its use in `natbib` (where it denotes using a full list of authors) and `jurabib` (where it denotes leaving out the title).

To get the content of a specific field, you can use the `\citefield` command. It issues a warning and prints nothing if the field does not exist in the entry.

<div style="border: 1px solid black; padding: 2px; display: inline-block;">16-5-51</div>	Vanoirbeek and Coray ... EP92 Vanoirbeek and Coray, EP92 EP92—Proceedings of Electronic Publishing, '92 Kant, “Kritik der praktischen Vernunft” KpV KpV	<pre>\usepackage[style=authortitle-ibid]{biblatex} \addbibresource{tlc.bib} \citeauthor{EP92}\ \ldots\ \citetitle{EP92}\ \cite{EP92} \ \citefield{EP92}{title} \ \citeauthor{kant:kpV}, \citetitle{kant:kpV}\ \cite*{kant:kpV} \ \citefield{kant:kpV}{shorthand}</pre>
--	--	--

¹This can also be “ibid” — use `\mancite` to avoid this.

Handling annotators

As was noted in Section 16.5.1 the `jurabib` package interprets the first optional argument of the citation commands as the name of an annotator and formats it in a special way. There is no direct support for this citation format in the generic styles provided by `biblatex`, so you have to turn to an external package here.

However, even then the entries that we used in the `jurabib` examples are unsuitable for `biblatex`: the two packages we present below expect entries with annotators to be of the entry type `commentary`. In addition, the `edition` field should be a number, and the language should be given in the `langid` field. Hence, our sample database also contains the entry `palandt` that is structured according to these conventions. It also sets the `pagination` field to enable `biblatex` to format the “page” numbers automatically.

Unfortunately, the two packages also use incompatible conventions for specifying the annotator: when using the `jura2` style, you must add an annotator in parentheses to the *post-note* argument, while the `biblatex-juradiss` style expects just the name in the *pre-note* argument. In short you have to choose up front, because changing from one to the other style (or to `jurabib`) involves extensive changes.

The “zit. als” (German for “cited as”) in the bibliography of the next example is triggered by the `howcited` key. The style uses three localization strings, `zitiertals`, `kommentarin`, and `bearbeiter`, currently set up only for the German language.

siehe in Palandt/Ellenberger, Abs. 119
... (Palandt/Heinrichs, Abs. 50)

Literatur

Palandt, Otto: Bürgerliches Gesetzbuch mit Nebengesetzen. 79. Aufl., München 2019 (zit. als Palandt/Bearbeiter).

```
\usepackage[ngerman]{babel}
\usepackage[style=jura2,
             howcited=true]{biblatex}
\addbibresource{tlc.bib}
\cite[siehe] [(Ellenberger) 119]{palandt}\
\ldots\ \parencite [(Heinrichs) 50]{palandt}

\printbibliography
```

16-5-52

The `biblatex-juradiss` package by Tobias Schwan and Herbert Voß offers the style `biblatex-juradiss`. It is based on the `authortitle-dw` style from the `biblatex-dw` bundle by Dominik Waßenhoven. In this style the annotator should be given directly in the *pre-note* argument, i.e., using the `jurabib` convention. The style shows the edition as a superscript. It works properly only in German, because various strings are hard-coded and cannot be localized.

... Ellenberger, in: Palandt⁷⁹, Abs. 119
... (Heinrichs, ebd., Abs. 50)

Literatur

Palandt, Otto, Bürgerliches Gesetzbuch mit Nebengesetzen, 79. Aufl., München 2019, *zitiert als: Bearbeiter*, in: Palandt⁷⁹.

```
\usepackage[ngerman]{babel}
\usepackage[style=biblatex-juradiss]{biblatex}
\addbibresource{tlc.bib}
\ldots\ \cite [Ellenberger] [119]{palandt}\
\ldots\ \parencite [Heinrichs] [50]{palandt}

\printbibliography
```

16-5-53

The rather special syntax for the annotators makes it difficult to switch to another style without changing the input. We demonstrate this by repeating the previous example with the style `oscola` — the output is definitively rather weird:

<p>... Ellenberger Bürgerliches Gesetzbuch mit Neben- gesetzen (Palandt) Abs. 119 ... (Heinrichs Palandt, Abs. 50)</p>	<pre>\usepackage[ngerman]{babel} \usepackage[style=oscola]{biblatex} \addbibresource{tlc.bib} \ldots\ \cite[Ellenberger][119]{palandt}\ \ldots\ \parencite[Heinrichs][50]{palandt}</pre>
<p>Literatur</p> <div style="border: 1px solid black; padding: 2px; display: inline-block;">16-5-54</div> Bürgerliches Gesetzbuch mit Nebengesetzen.	<pre>\printbibliography</pre>

16.6 The verbose system

A verbose citation system is a variant of the author-title format with the unique property that the first time — or the first time in a sectioning unit — a work is cited, then a full, *verbose* reference is given, usually in a footnote. Later references then use a shorter version that is built from the author names and the title, a shorter title, or a special shorthand — sometimes introduced in the first reference with “*cited as ...*”. Repeated citations typically make use of scholarly abbreviations like *ibidem* or *loc. cit.*

A dedicated bibliography list is not strictly needed in such a system, but if given, it can show additional information such as a DOI. The verbose citation system is not supported by standard L^AT_EX; it requires the `jurabib`¹ or `biblatex` package.

We start this section with the description of the `bibentry` package, a first attempt for basic support of verbose citations when using a B^BT_EX workflow. It allows insertion of a full citation in the running text but has no automatic test for the first citation or repeated citations, and shorter citations are mostly in the author-date format (or even only a number if `natbib` is used in numeric mode). We then continue with a description of `biblatex`’s approach to verbose citations.

16.6.1 bibentry — Full bibliographic entries in running text

As mentioned in the introduction of this section, instead of grouping all cited publications in a bibliography, it is sometimes required to directly typeset the full information the first time a publication is referenced. To help with this task Patrick Daly developed the `bibentry` package as a companion to the `natbib` package.

`\nobibliography{BBTEX-database-list}` `\bibentry{key}`

These commands work as follows: instead of the usual `\bibliography` command, which loads the `.bbl` file written by B^BT_EX and typesets the bibliography, you use `\nobibliography` with the same list of B^BT_EX database files. It reads the `.bbl` and

¹Refer to Section 16.5.1 for an overview of `jurabib`’s handling of verbose citations in conjunction with its support for author-title citations.

processes the information so that references to entries can be made elsewhere in the document. To typeset a citation with the full bibliographical information, use `\bibentry`. The usual author-date citation can be produced with any of the `natbib` commands. Here is an example:

For details see Knuth, D. E., *Typesetting Concrete Mathematics*, *TUGboat*, 10(1), 31–36, 1989. General information can be found in Knuth, D. E., *The TeXbook*, *Computers and Typesetting*, vol. A, ix + 483 pp., Addison-Wesley, Reading, MA, USA, 1986 and in *Goossens et al.* [1994, 1997].

As shown by Knuth [1989] ...

```
\usepackage{bibentry,natbib}
\bibliographystyle{agu}
\AtBeginDocument{\nobibliography{t1c}}
```

For details see `\bibentry{Knuth:TB10-1-31}`. General information can be found in `\bibentry{Knuth-CT-a}` and in `\citet{TLC94,LGC97}`.

As shown by `\citet{Knuth:TB10-1-31} \ldots`

16-6-1

Potential pitfalls 

There are a number of points to be noted here: the `\nobibliography` command must be placed inside the body of the document but before the first use of a `\bibentry` command. In the preamble a `\nobibliography` is silently ignored, and any `\bibentry` command used before it produces no output. Such a command is therefore best placed directly after `\begin{document}` or, if you prefer it in the preamble, by placing it inside `\AtBeginDocument` as we did above.

Another potential problem relates to the choice of BibTeX style. The `bibentry` package requires the entries in the `.bbl` file to be of a certain form: they must be separated by a blank line, and the `\bibitem` command must be separated from the actual entry text by either a space or a newline character. This format is automatically enforced for BibTeX styles produced with `custom-bib`, but other BibTeX styles may fail, including some that work with `natbib` by its own.

Watch out for
punctuations within
the entry

The `\bibentry` command automatically removes a final period in the entry so that the reference can be used in mid-sentence. However, if the entry contains other punctuation, such as a period as part of a note field, the resulting text might still read strangely. In that case the only remedy might be to use an adjusted BibTeX database entry.

One can simultaneously have a bibliography and use the `\bibentry` command to produce full citations in the text. In that case, place the `\bibliography` command to produce the bibliography list at the point where it should appear. Directly following `\begin{document}`, add the command `\nobibliography*`. This variant takes no argument, because the BibTeX database files are already specified on the `\bibliography` command. As a consequence, all publications cited with `\bibentry` also automatically appear in the bibliography, because a single `.bbl` file is used.

16.6.2 biblatex's approach to verbose citations

Typesetting the full information of a publication is supported by `biblatex` twofolds. On the one hand you can typeset full citations with any style with the `\fullcite` command. It prints a citation in the same format as in the bibliography. Similar to the

`\bibentry` command, there is no final period in the entry so that the reference can be used in mid-sentence.

For details see Donald E. Knuth. “Typesetting Concrete Mathematics”. In: *TUGboat* 10.1 (Apr. 1989), pp. 31–36. ISSN: 0896-3207 and also Goossens, Rahtz, and Mittelbach [1].

`\usepackage{biblatex}`
`\addbibresource{tlc.bib}`

For details see `\fullcite{Knuth:TB10-1-31}`
and also `\textcite{LGC97}`.

16-6-2

On the other hand, a suitable style can be loaded to use the verbose citation system in a document. With such a style the `\textcite` typesets the author name and creates a footnote with the reference, while `\autocite` or `\footcite` creates only a footnote. If an inline citation is wanted, `\cite` and `\parencite` can be used. The styles make use of various trackers to identify the first reference and repeated citations.

The `biblatex` package ships with a number of styles supporting this convention, i.e., `verbose`, `verbose-ibid`, `verbose-note`, `verbose-inote`, and `verbose-trad1` to `verbose-trad3`. They mainly differ in the way they handle recurrent authors, titles, and page numbers in repeated citations. More styles are provided by various external packages; see Section 15.7.3 on page 432.

In the next example we show the style `verbose-trad1`. Note how repeated citations are handled in the example: for the Knuth citation “*ibid.*” is used to repeat the immediately preceding citation, while the author name and “*op. cit.*” are used for a farther away citation of the same work. Compare this with the handling of the Kant citation. Its entry has a `shorthand` field in the `.bib`-file, and the citation style adds “*henceforth cited as KpV*” to the first citation and uses the shorthand in subsequent citations.

... Knuth¹ see² Knuth³ Knuth⁴ see⁵ ...

`isbn=false]{biblatex}`
`\addbibresource{tlc.bib}`

`\ldots\ citation\autocite{Knuth:TB10-1-31}`
`and\autocite{Knuth:TB10-1-31}`
`footnote\footnote{Don’t use footnotes, Don!}`
`mixup\autocite{Knuth:TB10-1-31}\ldots`

16-6-4

In Example 16-6-3 you have observed that when a reference contains a `pages` field and has a post-note that we end up with two page specifications in the reference, e.g., “pp. 31–36, p. 33”, and this may be confusing to the reader. The option `citepages`¹ controls how to deal with those fields in this case. The default value `permit` allows the duplication, `suppress` unconditionally suppresses the `pages` field, `omit` suppresses it only if there is a clashing post-note, and `separate` inserts the text “esp.”:

<p>... Knuth¹ ...</p> <hr/> <p>¹see Donald E. Knuth. “Typesetting Concrete Mathematics”. In: <i>TUGboat</i> 10.1 (Apr. 1989), pp. 31–36, esp. p. 33.</p>	<pre>\usepackage[style=verbose-trad1,isbn=false, citepages=separate]{biblatex} \addbibresource{tlc.bib} \ldots \textcite[see] [33]{Knuth:TB10-1-31} \ldots</pre>	<div style="border: 1px solid black; padding: 2px; width: fit-content;">16-6-5</div>
--	---	--

With the option `ibidpage` you can control how references to the same page in repeated citations are handled. When set to `true`, the post-note is suppressed in an *ibidem* citation if the last citation was to the same page range. The next example demonstrates this in the second footnote:

<p>... Knuth¹ Knuth² Knuth³ ...</p> <hr/> <p>¹see Knuth, “Typesetting Concrete Mathematics”, p. 33. ²see <i>ibid</i>. ³see <i>ibid.</i>, p. 32.</p>	<pre>\usepackage[style=verbose-trad1,isbn=false, ibidpage=true]{biblatex} \addbibresource{tlc.bib} \ldots \textcite[see] [33]{Knuth:TB10-1-31} \quad \textcite[see] [33]{Knuth:TB10-1-31} \quad \textcite[see] [32]{Knuth:TB10-1-31} \ldots</pre>	<div style="border: 1px solid black; padding: 2px; width: fit-content;">16-6-6</div>
---	--	--

The `verbose-note` and `verbose-inote` styles add a back-reference to the earlier note containing the full citation similar to the `lookat` option from *jurabib* described on page 518. Below we repeat Example 16-5-21 using `verbose-inote` this time. The “i” in the style name indicates that it uses “*ibidem*”. Note that “*ibidem*” is not used for the first citation on the page.

<p>Also discussed is generating PDF² and HTML.³</p> <hr/> <p>²Goossens and Rahtz, see n. 1, chap. 2. ³<i>Ibid.</i>, chap. 3–4.</p>	<pre>\usepackage[style=verbose-inote]{biblatex} \addbibresource{tlc.bib} \ldots to use \LaTeX{} on the web.\autocite{LWC99} \newpage % Next page shown on the left: Also discussed is generating PDF\autocite[chap.~2]{LWC99} and HTML.\autocite[chap.~3--4]{LWC99}</pre>	<div style="border: 1px solid black; padding: 2px; width: fit-content;">16-6-7</div>
---	---	--

If you want terms such as “*ibidem*” to be printed in italics, you may redefine `\mkibid`. We do this in the next example (a repeat of 16-6-3) but set also the language to German and use `\bibstrings` to demonstrate how terms are localized.

The term `see` then becomes “*Siehe*” and the term `confer` (Latin for “compare”) changes from “*Cf.*” to “*Vgl.*” — the German abbreviation for “*Vergleiche*”.

¹If using a verbose style from an external package, consult its documentation to find out if similar options are available.

16.7 biblatex — One ring to rule them all

We now turn to a more in-depth discussion of the biblatex package [79]. As could be seen in the previous sections, biblatex supports in a consistent way all citation styles and various citation commands either directly or through external supporting packages.

It achieves this through a change of the rôle of the .bbl file. All other packages reviewed up to this point use a .bbl file that contains a standard thebibliography environment to typeset the bibliography. The \bibitem commands in there also pass the data needed to format the citations back to \LaTeX : in standard \LaTeX only a number or a label; with natbib and other packages the author and the date information. The jurabib package increases the amount of structured data passed back drastically — an example was given in the introduction to the author-date format on page 488. However, in all implementations the main purpose of the .bbl file remains the production of the *printed* representation of the bibliography and therefore ends up containing a mix of typesetting and data commands.

This changed radically in 2006 with the initial release of the biblatex package by Philipp Lehman. With biblatex the .bbl file no longer contains a thebibliography environment and several \bibitem commands. It does not contain any typesetting instructions at all, but only a structured, preprocessed, and sorted representation of the bibliography data. The (shortened and redacted) data of a publication looks, for example, like this:

```
\entry{LGC97}{book}{%
  \name{author}{3}{}%
  {\un=0,uniquepart=base,hash=0743efb276e9219ee664a9b3dbd60619}{%

```

As can be seen, biber passes more than the content from the .bib file. It also creates initials and metadata like hashes, and it records which field should be used as the source for the label name — a work without the author field will here perhaps use the editor field instead. As with the jurabib approach, such a representation of the bibliography data cannot be created manually without much work and so requires an external tool such as biber.

The shift to such a structured .bbl — made possible by the increasing memory¹ and speed available in the T_EX-engines, which allows you to store and process more commands during the compilation — has several advantages:

- Every field of an entry can be used in citations, and thus a large variety of styles can be defined and used. biblatex is not confined to a subset of citation systems — it supports them all.
- Because the .bbl file is not used for printing, it can be loaded at the beginning — this can reduce the number of compilations needed to resolve the references.
- The data provided in the .bbl file can be reused as often as needed. This makes it easy to typeset more than one bibliography with various filter conditions.
- Changes to the format of the citations or the bibliography and even the creation of a complete new style can be done fully with L^AT_EX commands.

*biber is
recommended, but
BibT_EX is possible too*

In early biblatex versions the .bbl file was created with BibT_EX and a special .bst style. To stay compatible with this workflow it is still possible to choose BibT_EX as the processor through the package option `backend=bibtex`. However, it is highly recommended to use biber (see Section 15.2.2), because not every feature offered

¹Very large bibliographies can still exhaust the available memory.

by biblatex can be faithfully backported to \LaTeX , and this can lead to hard to spot output differences.

Recall that due to the differences between biblatex/biber and standard workflows with \LaTeX , some changes to the .bib files are required or recommended; see Section 15.3.

16.7.1 Basic biblatex setup

The workflow and how to set up a basic document for biblatex has already been described in Section 15.4. The following example therefore repeats only the core commands: the `style` key to set up the main style (here an author-title format), the preamble-only command `\addbibresource` to declare which .bib files should be used as resources, a citation command to select the entry — we use here `\textcite`, which is similar to `\citet` of natbib — and `\printbibliography` to print the bibliography.

16.7.2 Package options

The package options of biblatex use a key/value syntax. A small number of the keys must be given as package options at load time:

Load-time options

backend The option allows setting the bibliography processor. The (recommended) default is `biber`; other options are `bibtex` and `bibtex8`.

style, citestyle, bibstyle These keys load the main style definitions for the citations and the bibliography. Style files have the extension `.cbx` (for `citestyle`) or `.bbx` (for `bibstyle`), and the value of the keys is the name of such a file without the extension. biblatex comes with a large number of styles — several have been presented in the previous sections — and more are provided by external packages (see Section 15.7.3 for an overview). Typically the style for the citations and the bibliography should be set simultaneously with the `style` key. They can be set to different styles with the keys `citestyle` and `bibstyle`, but not every combination is sensible: a numeric citation style, for example, is useless if the chosen bibliography style does not show any numbers.

natbib, mcite These options load compatibility modules for the packages `natbib` and `mcite/mciteplus`. They provide implementation of the commands of these packages, which are very similar (but not identical) in syntax and function to the original commands and can make the transition of existing documents to biblatex easier.

Setting options in the document preamble

Besides these load-time options, biblatex knows a large number of other keys. These keys can be set as package options or alternatively in the configuration file `biblatex.cfg` or in the preamble with

```
\ExecuteBibliographyOptions[entrytype,...]{key=value,...}
```

The optional argument *entrytype* allows one to restrict some options to specific types such as `article` or `inproceedings`.

16.7.3 Citing with biblatex

The biblatex package defines a large set of citation commands for a variety of use cases, including citations in the text (`\textcite`), in parentheses (`\parencite`), as footnotes (`\footcite`), or — in some styles — as superscript (`\supercite`). Other commands capitalize the name (e.g., `\Textcite`). In addition, commands like `\citeauthor` or `\citefield` allow you to refer to a specific name or field of an entry.

There are flexible commands like `\smartcite` and `\autocite` that can change their behavior depending on the context or package options.

If the package option `natbib` is used, reimplementations of the citation commands of the `natbib` package are available too. The package also provides tools to create more citation commands if needed.

The argument structure for the different citation commands is identical. It is exemplified here with the `\cite` command:

```
\cite{key1,key2,...}   \cite[post-note]{key1,key2,...}
                        \cite[pre-note][post-note]{key1,key2,...}
```

Two optional arguments

Similar to the citation commands of `natbib` all citation commands in `biblatex` have one mandatory argument, which takes a comma-separated list of keys, and two optional arguments for the *pre-note* and the *post-note*. If only one optional argument is used, it is taken to be the *post-note*. If only a *pre-note* is wanted, an empty argument for the *post-note* must be added.

Automatic formatting of page numbers

The *post-note* usually contains page numbers or page ranges. `biblatex` parses this argument and if it matches a simple pattern of page numbers and ranges, it formats the data as required by the style and the language. Page numbers should therefore be entered as arabic or roman numerals, ranges should be denoted by a single hyphen, and suffixes for “page sequences” should be added with the commands `\psq` and `\psqq`. `biblatex` converts the hyphen into an en-dash and adds localized and configurable prefixes like “p.”, “S.”, or “S” automatically — to suppress an automatic page prefix use the command `\noppp`. The “pagination scheme” can be changed or suppressed on a per-entry basis by setting the `pagination` field in the `.bib` file.

If the page numbers have some unusual format or if there is some additional text in the *post-note* argument, then page numbers must be formatted manually. In such cases prefixes can be added with the commands `\pno` and `\ppno`, and numbers can be formatted with `\pnfmt`.

Example 16-7-2 demonstrates the various commands. Note that in French ‘p.’ is used even for multiple pages and that the range is typeset with a shorter hyphen. The last line of the example demonstrates the effect of the pagination field: it has been set to ‘section’ for this entry and so § is used as page prefix.

16-7-2

The following two examples show the output of the most frequently used pre-defined citation commands in the two currently dominant citation systems: numeric and author-date. The `\autocite` command allows switching the citation command with a package option — first we use `inline`, which changes it to `\parencite`, and in the second example `footnote`, which gives as expected `\footcite`. This allows, for example, switching the citation style from author-date to numeric without having to adapt the source to avoid forlorn and odd-looking numbers in a footnote. There is no difference between `\cite` and `\parencite` in a numeric style, but the later command should be preferred if a citation in parentheses is wanted after a switch to an author-based style. All citation commands including `\footcite` and `\autocite` can be input with a space before them, because `biblatex`, if necessary, removes that space. This is important for `\autocite`, because it gives the right output also when its output is an inline citation. With `useprefix`, the examples force the name to start with “von” to show the effect of the capitalizing citation variants.

[see 1, p. 5]	<code>\usepackage[autocite=inline,</code>

16-7-4

*Lost punctuation
after a citation* 

The biblatex package provides elaborate facilities designed to manage and track punctuation and spacing. The commands provided are mainly meant for style authors: they help prevent unwanted double punctuation marks if fields are missing or contain their own punctuation. In some cases the working of the punctuation tracker can also bite users because it can have an at first surprising effect that a punctuation symbol in the post-note “eats up” a following punctuation symbol in the text.

Example 16-7-5 demonstrates this for a semicolon: after a period it is suppressed, while it stays after an exclamation mark.

It is possible to overrule the behavior locally: `\bibsentence` marks the beginning of a sentence and so also hides all preceding punctuation marks. The counterpart is `\nopunct`, which suppresses the following punctuation:

	<code>\usepackage[style=authoryear]{biblatex}</code>
	<code>\addbibresource{tlc.bib}</code>
see Knuth 1986, for the details.	<code>\cite[see][for the details.]{Knuth-CT-a}; \\\</code>
see Knuth 1986, for the details!;	<code>\cite[see][for the details!]{Knuth-CT-a};</code>
see Knuth 1986, for the details.;	<code>\cite[see][for the details.\bibsentence]{Knuth-CT-a}; \\\</code>
see Knuth 1986, for the details!	<code>\cite[see][for the details!\nopunct]{Knuth-CT-a};</code>

16-7-5

16.7.4 Indexing citations automatically

Indexing can be activated with the package option `indexing`. It takes the values `true`, `false`, `cite`, or `bib`. The last two values restrict indexing either to citations or to bibliographies. By default biblatex adds the author names and the title to the index. In the next example we demonstrate how to redefine the relevant bibliography macro `citeindex` so that only the name is indexed.

Index

Goossens, Michel, 6	<code>\usepackage{makeidx} \makeindex</code>
Knuth, Donald E., 6	<code>\usepackage[indexing=cite]{biblatex} \addbibresource{tlc.bib}</code>
Mittelbach, Frank, 6	<code>\renewbibmacro{citeindex}{\ifciteindex{\indexnames{labelname}}{}}</code>
Rahtz, Sebastian, 6	<code>\textcite{LGC97}, \textcite{Knuth-CT-a} % p.6 (not shown)</code>
	<code>\newpage \printindex % p.7 (shown on the left)</code>

16-7-6

16.7.5 Back references and links

Sometimes it is useful to have a list of pages where a work has been cited in the bibliography. Such back references are fully supported by biblatex, and they are enabled with the option `backref`. The option `backrefstyle` allows you to set how consecutive pages are handled; by default a sequence of three or more pages is compressed to a range.

biblatex works well together with hyperref. If hyperref is loaded, citations, back references, and URLs are turned into active links. The following example shows such links in blue:

Smith and Webb (2021)

References

Smith, Joe and Henry Webb (2021). URL:
<https://some.url> (visited on
09/01/2021) (cit. on pp. 6, 7).

```
\usepackage[backref,style=authoryear]{biblatex}
\addbibresource{tlc-ex.bib}
\usepackage{hyperref}
\hypersetup{colorlinks,allcolors=blue}

\textcite[url:e] % p.6 (not shown)
\newpage % p.7 (shown on the left)
\textcite[url:e]
\raggedright \printbibliography
```

16-7-7

16.7.6 Bibliography entries with multiple authors

Longer lists of names (authors, editors, publishers, etc.) are often truncated after a defined number of names (with *et al.* or something similar added at the end). With biblatex this can be controlled independently for the citations in the document, the entries in the bibliography, and, if necessary, for sorting within the bibliography.

For citations there are `maxcitenames` (default 3) and `mincitenames` (default 1). If the number of names in a citation exceeds `maxcitenames`, the list is truncated and only `mincitenames` names are shown; otherwise, all names are displayed. You can alter both values according to your needs but `mincitenames` should always be lower than or equal to `maxcitenames`. This means, assuming the defaults are used, that a citation with four or more authors is shown with only one author name followed by “et al.”, while a citation with two or three authors displays all author names.

Baumbach et al. (2002)

Goossens, Rahtz, and Mittelbach (1997)
Goossens and Rahtz (1999)

```
\usepackage[style=authoryear]{biblatex}
\addbibresource{tlc.bib}

\textcite{zpo} \ \ % 4 authors
\textcite{LGC97} \ \ \textcite{LWC99} % 2-3 authors
```

16-7-8

If you always want to enforce a certain setting for an entry, you can add an options line into your .bib file, e.g., in the zpo entry:

```
options = {maxcitenames=4,maxbibnames=4},
```

To control name lists in the bibliography the same functionality is offered through the keys `maxbibnames` and `minbibnames`. This allows you to show more (or fewer) names in the bibliography compared to what is shown in a citation within the document. For example, you might always want the bibliography to display up to four

names, with or without truncation, while you might only want to show one name in citations. In this case, the correct setting would be the following:

```
maxcitenames=1,minbibnames=4,maxbibnames=4
```

If the bibliography is sorted, then by default the sorting algorithm uses the name lists truncated according to the `maxbibnames` and `minbibnames` key settings. If this is not appropriate, you can use the keys `maxsortnames` and `minsortnames` to overwrite that default.¹ For example,

```
minbibnames=3,maxbibnames=3,minsortnames=1,maxsortnames=1
```

would show up to three names per entry in the bibliography but would disregard all authors except the first when sorting the bibliography.

However, most of the time identical settings are wanted for the minimum and maximum values. Therefore, `biblatex` also offers the two convenience keys `maxnames` and `minnames` to set all of the three `max...names` and `min...names` keys in one go.

All eight keys can only be set as options to the package or in the preamble.

16.7.7 Unambiguous citations

Citations must be unambiguous: they are labels pointing to the bibliography, and a reader must be able to identify the corresponding entry. For a numeric system a unique label merely requires increasing a counter. Author-based styles have to cater for the case that different authors and author lists might share the same names. As already described in the introduction of this chapter, author-based styles avoid ambiguities by adding initials (or even the full given name), by adding an extra year marker, or by showing more authors.

By default `biblatex` prefers to make the names unique by adding initials or the full given name. Thus, in the following example the two *Kirk* and *Doe* authors are differentiated by their initials, *Pyne* by the full given names, and *Webb* by extra year markers. The *Doe* authors get initials despite the fact that the year would already make their label unique because that makes it easier for humans to identify the correct publication.

	<code>\usepackage[style=authoryear]{biblatex}</code>
	<code>\addbibresource{tlc-ex.bib}</code>
Smith 2020; J. Kirk 2020; B. Kirk 2020	<code>\cite{smith,kirk1,kirk2} \\\</code>
Joe Pyne 2020; Jill Pyne 2020	<code>\cite{pyne1,pyne2} \\\</code>
J. Doe 2020; B. Doe 2019	<code>\cite{doe1,doe2} \\\</code>
Webb 2020a; Webb 2020b	<code>\cite{webb1,webb2}</code>

16-7-9

This default behavior with its mix of names with and without initials and given names is not to everyone's liking, but it has the huge advantage of creating quite short citations that nevertheless allow the reader to identify almost all authors directly in the text without having to interrupt the reading and check the entry in the bibliography.

¹If both `...bibnames` and `...sortnames` are specified they have to be in that order to take effect.

The output can be changed with the option `uniquename`. For example, with the setting `uniquename=init`, only initials are used and only for entries where initials are of no use in making the names unique, e.g., because they are identical, as in the two “Pyne” entries, an extra year marker is added instead.¹

16-7-10	Smith 2020; J. Kirk 2020; B. Kirk 2020 Pyne 2020b; Pyne 2020a J. Doe 2020; B. Doe 2019 Webb 2020a; Webb 2020b	<pre>\usepackage[style=authoryear,uniquename=init]{biblatex} \addbibresource{tlc-ex.bib} \cite{smith,kirk1,kirk2}\ \cite{pyne1,pyne2}\ \cite{doe1,doe2}\ \cite{webb1,webb2}</pre>
---------	--	---

The given names can be suppressed altogether with `uniquename=false`:

16-7-11	Smith 2020; Kirk 2020b; Kirk 2020a Pyne 2020b; Pyne 2020a Doe 2020; Doe 2019 Webb 2020a; Webb 2020b	<pre>\usepackage[style=authoryear,uniquename=false]{biblatex} \addbibresource{tlc-ex.bib} \cite{smith,kirk1,kirk2}\ \cite{pyne1,pyne2}\ \cite{doe1,doe2}\ \cite{webb1,webb2}</pre>
---------	--	--

To make citations with more than one author unique, biblatex again adds initials, given names and extra year markers, and if needed shows more authors. Similar to the handling of single authors, it also tries to make the authors identifiable. For example, the last citation *J. Kirk* has an initial to distinguish the author from *M. Kirk* in the third citation.

*Unambiguous
author lists*

16-7-12	Smith et al. 2020 H. Pyne et al. 2020 J. Pyne and M. Kirk 2020 J. Pyne and Webb 2020a J. Pyne and Webb 2020b J. Kirk et al. 2020	<pre>\usepackage[style=authoryear,maxcitenames=1]{biblatex} \addbibresource{tlc-ex.bib} \cite{list0}\ \cite{list1}\ \cite{list2}\ \cite{list3}\ \cite{list4}\ \cite{list5}</pre>
---------	---	--

The list handling can be configured with the option `uniquelist`. The following example shows the same set of citations but with `uniquelist=false`, which restricts the list length to the `maxcitenames` value. *Kirk* is now shown without the initials because the author *M. Kirk* is no longer visible. This makes the citations quite concise at the cost of readability, because it is more difficult to identify the correct work without checking in the bibliography.

16-7-13	Smith et al. 2020 H. Pyne et al. 2020 J. Pyne et al. 2020a J. Pyne et al. 2020b J. Pyne et al. 2020c Kirk et al. 2020	<pre>\usepackage[style=authoryear,maxcitenames=1, uniquelist=false]{biblatex} \addbibresource{tlc-ex.bib} \cite{list0}\ \cite{list1}\ \cite{list2}\ \cite{list3}\ \cite{list4}\ \cite{list5}</pre>
---------	--	--

¹Initials can be forced, even in that case, by redefining the `labelname` format.

*Ambiguous
author-title
entries in rare cases*

In an author-title style, identical citations pointing to different references are possible if the author and title are identical. The existing author-title style implementations do not try to avoid that rare case. For styles or documents that want better control here, biblatex offers the options `labeltitle` and `labeltitleyear`. They cause biber to check the author and title (and also the year) for uniqueness and to add data fields that can be queried in tests by style authors.

16.7.8 Printing the bibliography

We now describe in detail the main command to print, filter, and format the reference list with the biblatex package.

```
\printbibliography[key/value options]
```

To typeset a bibliography add `\printbibliography` at the place where it should appear. It can be used as often as wanted. If the list is empty, e.g., if the document does not contain any citation commands or if biber has not been called yet, nothing is printed, and a warning is added to the `.log` file:

LaTeX Warning: Empty bibliography on input line 57.

The `\printbibliography` command adds a heading before the reference list. By default it is formatted as an unnumbered top-level sectioning command of the class using `\refname` or `\bibname` as content.

*Changing the
heading*

The heading can be adapted with two keys: `title` sets the text of the heading, and `heading` allows you to change the formatting of the heading. For example, the value `subbibliography` switches a level down in the sectioning hierarchy, the value `bibintoc` adds the bibliography to the table of contents, and with `bibnumbered` a numbered sectioning command is used. To suppress the heading altogether, the value `none` is provided. More options can be found in the documentation. It also describes how to define new heading types with `\defbibheading`.

```
\printbibheading[key/value options]
```

It is sometimes necessary to add only a heading for example as a common title for subdivided bibliographies. This can be done with the standard sectioning commands of the class but also with `\printbibheading`. It also knows about the keys `heading` and `title`.

```
\defbibnote{name}{text}
```

To add arbitrary text to the bibliography two keys can be used in the optional argument of `\printbibliography`: `prenote` for text between the heading and the

actual bibliography and `postnote` for text after the list. The value of both keys is a *name* referring to a text declared before with the `\defbibnote` command.

1 My References

Some text before the bibliography.

```
\usepackage[isbn=false]{biblatex}
\addbibresource{tlc.bib}
\defbibnote{prebib}
{Some text before the bibliography.}

\nocite{Knuth-CT-a,Knuth:TB10-1-31}
\printbibliography
[heading=bibnumbered,prenote=prebib,
title=My References]
```

A powerful feature of `\printbibliography` is the ability to apply filters to print only a subset of the entries of a bibliography, for example only articles, entries with a specific keyword, or entries cited in a specific part of the document and so to split the references into sublists by topic or location. Various common filters can be set directly with key/value options, and biblatex also provides interfaces to define more specialized filters.

Filtering entries

For some common selections of field values of the references biblatex offers predefined keys: `type`, `nottype`, `subtype`, `notsubtype`, `keyword`, and `notkeyword`. They expect as a value a type, like `article` or `book`, or a keyword and can be used multiple times to build up lists. Example 16-7-15 demonstrates some of these keys. Be aware that splitting a bibliography in many parts can make it difficult to find a reference. It is not obvious if one should search in the books or somewhere else for “Pyne (2020a)”. Thus, such splits should normally not replace but accompany a full bibliography.

Common selections of field values

Doe (2015), Pyne (2020b), Pyne (2020a), Kirk (2020)

Books

Kirk, Maria (2020). *An important book*.
Pyne, Mike (2020a). *A book*.

Not Books

Doe, Jill (2015). “An article”. In: *Journal A*.
Pyne, Mike (2020b). “An important article”. In: *Journal B*.

Important

16-7-15

Kirk, Maria (2020). *An important book*.
Pyne, Mike (2020b). “An important article”. In: *Journal B*.

```
\usepackage[style=authoryear]{biblatex}
\addbibresource{tlc-ex.bib}

\textcite{article1}, \textcite{article2},
\textcite{book1}, \textcite{book2}

\printbibliography
[type=book,title=Books]

\printbibliography
[notype=book,title=Not Books]

\printbibliography
[keyword=important,title=Important]
```

The following example demonstrates another problem with split bibliographies. By default the labels used are the ones from the full, alphabetically sorted bibliography,

and this means entries in subsets are numbered in a rather wild way. To keep this and later examples small, we reduced the spacing between the entries by setting `\bibitemsep` to zero.

Doe [1], Pyne [4], Pyne [3], Kirk [2]

Books

[2] Maria Kirk. *An important book*. 2020.

[3] Mike Pyne. *A book*. 2020.

Other

[1] Jill Doe. “An article”. In: *Journal A* (2015).

[4] Mike Pyne. “An important article”. In: *Journal B* (2020).

```
\usepackage{biblatex}
\addbibresource{tlc-ex.bib}
\setlength\bibitemsep{0pt}
\textcite{article1},
\textcite{article2},
\textcite{book1},
\textcite{book2}
\printbibliography
[type=book,title=Books]
```

```
\printbibliography
[notttype=book,title=Other]
```

16-7-16

`biblatex` has a number of options to handle this problem. The most important one is the package option `defernumbers`. With it numbers are assigned in the order that the entries appear in a bibliography. This improves our example greatly, but note that this works satisfactorily only with disjoint bibliographies.

Doe [3], Pyne [4], Pyne [2], Kirk [1]

Selection by cite location

To select the entries cited in a specific part of the document like a chapter, the `keys` section and `segment` are provided. They expect as a value the number of a reference section or a reference segment. How to define and use such sections and segments is described in Section 16.7.10 on page 556.

```
\DeclareBibliographyCategory{category}
\addtocategory{category}{key}
```

Selection by category

Categories allow splitting bibliographies into topics assigned to the entries on the fly in the document. With `\DeclareBibliographyCategory` you declare a category, where the value is an arbitrary name. With `\addtocategory` a `key` can be assigned to a `category`. To filter the bibliography by one or more categories the `keys` category

and `notcategory` are provided. A typical use case for categories is to differentiate between cited works and works for further reading added with the `\nocite` command. This is shown in the following example. It makes use of the hook `\AtEveryCitekey` that is executed for every key in a citation command. With the `\thefield` command we retrieve the current key of the entry and add it to the category `cited`.

\printbibliography[category=cited]
\printbibliography[notcategory=cited,
                  title=Further reading]
```

16-7-18

By default the various filters are applied in an additive way, so all conditions must be met by an entry:

```
type=article,keyword=important,keyword=research,category=cited
```

This would select only articles that have both keywords in their `keywords` field and have been cited in the document — in our examples so far only `article2` would be printed if cited.

In the case that the standard selection keys are not sufficient, a more complicated filter can be defined and then used in the options of `\printbibliography` with `filter=filter name` or `check=check name`.

```
\defbibfilter{filter name}{expression}
```

The command `\defbibfilter` expects as its second argument a boolean expression based on the logical operators `and`, `or`, and `not` and some of the atomic tests discussed earlier. Parentheses surrounded by spaces can be used to specify the precedence of operators. However, there should be no spaces around the equal sign.

```
\defbibfilter{cited-or-important}{
  category=cited or
  ( keyword=important and not keyword=research )
}
\printbibliography[filter=cited-or-important]
```

This prints all entries that have been cited or that contain the keyword `important` but not the keyword `research`, so it would exclude `article2` if not cited.

```
\defbibcheck{check name}{code}
```

The `\defbibcheck` declaration is more low-level: its *code* argument can be arbitrary code using any test from the `biblatex` and the `etoolbox` package, and it can use all bibliography data of the current entry. The result of such a check is considered to be false (suppressing the printing of an entry) if the code leads to the execution of `\skipentry`. In the following example we print only entries published before the year 1988. The check first tests if the year actually contains a number — a tiny detail, but one that avoids strange errors if you use the check with arbitrary input data.

Kant, Immanuel (1968). “Kritik der praktischen Vernunft”. In: *Kants Werke. Akademie Textausgabe*. Vol. 5: *Kritik der praktischen Vernunft. Kritik der Urtheilskraft*. Berlin: Walter de Gruyter, pp. 1–163.

\defbibcheck{before1988}{%
  \iffieldint{year}{%
    \ifnumless{\thefield{year}}{1988}%
      {}{\skipentry}}%
  {\skipentry}}
\nocite{*}
\printbibliography[heading=none,
  check=before1988]
```

16-7-19

16.7.9 The sorting of the bibliography

The sorting of the bibliography can be set with the package option `sorting`. Values are for example `none` (unsorted), `nyt` (“name year title”), or `ydnt` (“year descending name title”). More sorting schemes can be defined with `\DeclareSortingTemplate`. Typically the sorting scheme is set by the style, and overriding it should be done with care — for example, `sorting=none` together with an author-based style would make the bibliography unusable if you think about it.

It is possible to print multiple differently sorted bibliographies in a document, for example, one sorted by author and one sorted by year, by starting a so-called “new reference context” that changes the way the citation labels are built and sorted in the bibliography.

```
\DeclareRefcontext{name}{key/value options}
\newrefcontext[key/value options]{name}
```

`\DeclareRefcontext` declares a named reference context with a number of key/value settings. `\newrefcontext` starts a new reference context referring back to the declared context. The *name* argument is, despite the braces surrounding it, actually optional — this slightly odd syntax is a result of providing backward compatibility — an unnamed context, e.g., `\newrefcontext{sorting=ynt,labelprefix=A}`, could be used too. However, using a name simplifies assigning a reference context to citations and allows you to keep your settings together in the preamble.

The following example shows how this can be used to add a second bibliography with a different sorting. We additionally use a filter and print only articles in the second bibliography.

16-7-20

When printing multiple bibliographies like this, a work can have more than one label — in the example a number or a number with the prefix “A” added by specifying a `labelprefix`. The same can happen in a less obvious way also with author-date or author-title labels. In such cases one has to decide which label should be used for the citations. By default biblatex uses the label from the last bibliography in which the citation was printed.¹

Because in the example the books are not shown in the second bibliography, the labels of the first bibliography are used for them, and we get as citations a — probably unwanted — mix of numbers with and without a prefix. This can be avoided by assigning the affected entry types or citation keys to a specific reference context to determine their labels. In the following example we assign all citations the labels of the first bibliography — for more complicated cases the documentation should be consulted.

16-7-21

¹This behavior has changed over time.

16.7.10 Document divisions

The biblatex package offers two concepts for document division: *reference sections* and *reference segments*. They can be started in various ways: with commands (`\newrefsection` and `\newrefsegment`), with environments (`refsection` and `refsegment`), or automatically at various sectioning units through package options like `refsection=chapter`. After a division has been created, it is possible to restrict a bibliography to the entries cited in this division with the keys `segment` and `section`; they take as the value the number of the division—in the current division you can access this number with `\therefsection` and `\therefsegment`.

*Reference sections
for independent
bibliographies*

A reference section encapsulates citations and bibliographies as if they were in a document of their own. Within such a reference section, all cited works are assigned labels that are local to the division: cross references and cite trackers are local too. Reference sections can also use resources (`.bib` files) specific to the division. Therefore, reference sections are useful if you want separate, *independent* bibliographies and bibliography lists. The typical use cases are articles in a journal where every article has its own specific bibliography. Reference sections can also be used for chapter bibliographies if the chapters build independent units, but it is important to realize that the same work may get assigned a different label in each reference section and so combining all entries in a global bibliography is not really possible.

*Reference segments
are filters*

Reference segments in contrast divide the document into parts that can be used as filters. They are useful if you want to show a selected view by chapter or section but want also a global bibliography because labels are unique across the segment boundaries. Reference segments can be used inside reference sections but not the other way round.

The next two examples demonstrate both division types. Note the extra year marker in “Smith, 2020a” and “Smith, 2020b”, which make the labels unique when the document is divided with reference segments and compare it with the “Smith, 2020” used for both works if reference sections are used instead.

	<code>\usepackage[style=authoryear, dashed=false]{biblatex}</code>
	<code>\addbibresource{tlc-ex.bib}</code>
... Smith 2020b ...	<code>\newrefsegment</code>
References of refsegment 1	<code>\ldots\ \cite{smith2020-1}\ \ldots</code>
Smith, Maria (2020b). <i>Another book</i> .	<code>\printbibliography</code>
... Smith 2020a ...	<code>[title=References of refsegment 1, segment=1]</code>
References of refsegment 2	<code>\newrefsegment</code>
Smith, Maria (2020a). <i>A book</i> .	<code>\ldots\ \cite{smith2020-2}\ \ldots</code>
Global bibliography	<code>\printbibliography</code>
Smith, Maria (2020a). <i>A book</i> .	<code>[title=References of refsegment 2, segment=2]</code>
Smith, Maria (2020b). <i>Another book</i> .	<code>\printbibliography[title=Global bibliography]</code>

When using reference selections, we do not need to select them explicitly if the bibliography is printed inside the reference section because the `\printbibliography` outputs only the works of the current reference section by default.

... Smith 2020 ...	<code>\usepackage[style=authoryear]{biblatex}</code>
	<code>\addbibresource{t1c-ex.bib}</code>
References of refsection 1	<code>\newrefsection</code>
Smith, Maria (2020). <i>Another book</i> .	<code>\ldots\ \cite{smith2020-1}\ \ldots</code>
	<code>\printbibliography[title=References of refsection 1]</code>
... Smith 2020 ...	<code>\newrefsection</code>
References of refsection 2	<code>\ldots\ \cite{smith2020-2}\ \ldots</code>
Smith, Maria (2020). <i>A book</i> .	<code>\printbibliography[title=References of refsection 2]</code>

16-7-23

If you wish to group all the bibliographies together (for example, at the end of the document), you can use the following commands:

`\bibbysection[key/value options] \bibbysegment[key/value options]`

They print the bibliographies of all reference sections or segments encountered so far. The title of such bibliographies should typically contain some number or reference to the chapter or section they refer to. For this purpose biblatex sets a label when starting a reference section. We demonstrate this in the next example by advancing the section counter and defining a heading that then references the label.

1 Article	<code>\usepackage[style=authoryear]{biblatex}</code>
... Smith 2020 ...	<code>\addbibresource{t1c-ex.bib}</code>
	<code>\defbibheading{subbibliography}{%</code>
	<code>\subsection*{References for Article</code>
	<code>\ref{refsection:\therefsection}}}</code>
2 Another article	
... Smith 2020 ...	
	<code>\section{Article} \newrefsection</code>
References	<code>\ldots\ \cite{smith2020-1}\ \ldots</code>
References for Article 1	
Smith, Maria (2020). <i>Another book</i> .	<code>\section{Another article} \newrefsection</code>
	<code>\ldots\ \cite{smith2020-2}\ \ldots</code>
References for Article 2	<code>\printbibheading</code>
Smith, Maria (2020). <i>A book</i> .	<code>\bibbysection[heading=subbibliography]</code>

16-7-24

16.7.11 Annotated bibliographies

If you want to generate an annotated bibliography, you can use the `reading` style. The annotation should be in the field `annotation` (or in the alias `annote` provided for jurabib compatibility).

The style produces entries like the following:

Computers and Graphics **jcg**

Computers and Graphics 35.4 (2011): *Semantic 3D Media and Content*.
ISSN: 0097-8493.

Annotations: This is a periodical entry with an issn field.

16-7-25

The `annotation` field can also be added to the bibliography made with styles that normally ignore this field. For example, you can insert the instruction to print the `annotation` field in the bibliography macro `finentry`, which is executed at the end of every entry.

Computers and Graphics (2011) 35.4:
Semantic 3D Media and Content.
ISSN: 0097-8493.
Annotation: This is a periodical
entry with an issn field.

```
\usepackage[style=authoryear]{biblatex}
\addbibresource{tlc.bib}
\DeclareFieldFormat{annotation}
  {\par\textsf{Annotation: #1}}
\renewbibmacro{finentry}{\setunit{\finentrypunct}}%
  \printfield{annotation}\finentry}
\nocite{jcg}
\raggedright \printbibliography[heading=none]
```

16-7-26

16.7.12 Bibliography lists

In some fields it is common to use shorthands or short titles in the citation and to provide lists to look up such abbreviations.

`\printbiblist[key/value options]{biblistname}`

This command, which was already used in Example 16-5-50 on page 535, allows one to print lists of abbreviations, shorthands, and similar material. It differs from a normal bibliography in that it formats all entries in the same way (with the same “bibliography driver” given in the `biblistname` argument); i.e., it does not differentiate by entry type as `\printbibliography` does. `biblatex` provides automatic support for such lists for various fields that are short versions of other fields. They are marked as “label field” in the package documentation.

Angenendt (2002) schrieb in „In Honore Salvatoris“ ...

Liste der Kurztitel

In Honore Salvatoris Angenendt, Arnold (2002). „In Honore Salvatoris – Vom Sinn und Unsinn der Patrozinienkunde“.

```
\usepackage[ngerman]{babel}
\usepackage{csquotes}
\usepackage[style=authoryear]{biblatex}
\addbibresource{tlc.bib}

\textcite{angenendt} schrieb in
\citetitle{angenendt} \ldots
\printbiblist[title=Liste der
  Kurztitel]{shorttitle}
```

16-7-27

16.7.13 Language support

The biblatex package collaborates with the babel package. For all declared languages biblatex loads special language definition files (extension .ltx) that contain definitions for all kinds of bibliography strings to produce textual material within citations and bibliography entries. At the moment more than 50 languages are supported.

Cicero, Marcus Tullius (1995). *De natura deorum. Über das Wesen der Götter*. Latin and German. Ed. and trans. by Ursula Blank-Sangmeister. With an afterw. by Klaus Thraede. Stuttgart: Reclam.

```
\usepackage[french,english]{babel}
\usepackage{csquotes}
\usepackage[style=authoryear]{biblatex}
\addbibresource{t1c.bib}
```

CICERO, Marcus Tullius (1995). *De natura deorum. Über das Wesen der Götter*. Latin et allemand. Éd. établie et trad. par Ursula BLANK-SANGMEISTER. Avec une postf. de Klaus THRAEDE. Stuttgart : Reclam.

```
\nocite{cicero}
\printbibliography[heading=none]
\selectlanguage{french}
\printbibliography[heading=none]
```

16-7-28

The language support is not restricted to the main language of the document: biblatex also reacts to language changes inside the document as shown above or when typesetting citation references.

When biblatex detects that babel (or polyglossia) is loaded, it checks if csquotes is loaded as well and if not issues a warning that this is recommended. The reason is that bibliography entries often use quotes around titles, etc. — these should preferably be typeset according to the conventions of the document language, and biblatex delegates that to the csquotes package. See Example 16-7-27 above.¹

 Management of quotes

Many of the localized strings can take two forms: a long and an abbreviated variant. To switch between both, the key `abbreviate` can be used:

Cicero, Marcus Tullius (1995). *De natura deorum. Über das Wesen der Götter*. Latin and German. Edited and translated by Ursula Blank-Sangmeister. With an afterword by Klaus Thraede. Stuttgart: Reclam.

```
\usepackage[english]{babel}
\usepackage[style=authoryear,
  abbreviate=false]{biblatex}
\addbibresource{t1c.bib}
\nocite{cicero}
\printbibliography[heading=none]
```

16-7-29

Languages and countries often have their own conventions how to sort words containing accented letters, digraphs, ligatures, or spaces. More than one set of rules can exist for a language; for example, “Ä” can in German be sorted like “Ae” (this is called the phonebook rule) or always after “A”. biber contains the relevant Unicode libraries, and by default biblatex uses the sorting rules from the main document language as set with babel. To select another sorting rule use the key `sortlocale`; allowed values are babel language names or standard identifiers for

¹We have not done this in every example to conserve space; thus, if you rerun some of the examples using both babel and biblatex, but not csquotes, you are going to see a warning.

the locale. For example, `sortlocale=de_DE_phonebook` switches to the German phonebook sorting rule. The following example shows on the left the sorting with the Swedish locale and on the right the same entries if English is the main language.¹

English Sorting	Swedish Sorting
Aachen, Georgina (n.d.). <i>Title AA</i> .	Aachen, Georgina (n.d.). <i>Title AA</i> .
Ånten, Georgina (n.d.). <i>Title Å</i> .	Vn, A (n.d.). <i>Title VN</i> .
Änten, Georgina (n.d.). <i>Title Ä</i> .	Wolf, Ceasar (n.d.). <i>Title B</i> .
Önten, Georgina (n.d.). <i>Title Ö</i> .	Vr, A (n.d.). <i>Title VR</i> .
Vn, A (n.d.). <i>Title VN</i> .	Ånten, Georgina (n.d.). <i>Title Å</i> .
Vr, A (n.d.). <i>Title VR</i> .	Änten, Georgina (n.d.). <i>Title Ä</i> .
Wolf, Ceasar (n.d.). <i>Title B</i> .	Önten, Georgina (n.d.). <i>Title Ö</i> .

```
\usepackage[swedish,english]
{babel}
\usepackage[style=authoryear]
{biblatex}
\addbibresource{locale.bib}
\AtBeginBibliography{\small}
% declaration for swe-nyt not shown
\nocite{*}
\printbibliography
[titled=English Sorting]
\newpage
\newrefcontext[sorting=swe-nyt]
\printbibliography
[titled=Swedish Sorting]
```

16-7-30

Recall from the discussion of additional bibliography fields (page 392, Section 15.3.2) that the language can also be set in the `.bib` file for individual references using the `langid` field and that the package option `autolang` governs how such entries are set if their language differs from the main language.

16.7.14 Distinguishing the author’s gender

Just like `jurabib`, the `biblatex` package offers the `BIBTEX` field `gender`, which takes the two-letter abbreviation shown in Table 16.2 on page 526 and additionally also the value `pp` for a plural and mixed-gender list. It depends on the style and also on the language, if and how the `gender` field is actually used. In the following example the female form “Eadem” is used for the first author because she was labeled with `gender=sf` in the `tlc-ex.bib` file. The example also shows that `biblatex`’s `\autocite` and `\footcite` commands work nicely together with the `footmisc` package.

Some¹ text referencing works² by Jane³
and works⁴ by Max.^{5,6}

```
\usepackage[multiple]{footmisc}
\usepackage[style=verbose-trad1]{biblatex}
\addbibresource{tlc-ex.bib}

Some\autocite{jane-1} text referencing
works\autocite{jane-2} by Jane\autocite{jane-1}
and works\footcite{max-1} by
Max.\footcite{max-2}\footcite{max-1}
```

16-7-31

¹Jane Doe. *A book*. 2020.
²Jane Doe. *A second book*. 2020.
³Eadem, *A book*.
⁴Max Pyne. *A book*. 2020.
⁵Max Pyne. *A second book*. 2020.
⁶Idem, *A book*.

¹Not all code for the example is shown, because it is normally not supported to use different sorting rules in one and the same document. Therefore, `swe-nyt` was explicitly declared as a second sorting template. If you are interested, look at the full example source.

16.7.15 Sentence casing

As already mentioned in Section 15.3.3, sentence casing with biblatex, i.e., turning all words except the first to lowercase, is not done by the bibliography processor but with \LaTeX code. This is a common practice in Anglo-Saxon bibliographies, typically used for titles of articles (but not books), but it would be wrong in many other languages, e.g., in German where nouns have to start with an uppercase letter.

For this, biblatex provides the command `\MakeSentenceCase` that can be used in formatting directives but also in other places. Its starred form is language aware and changes the case only if the language in the field `langid` or — if missing — the current language matches one of languages stored in a special list. By default this list contains only various English variants, but if necessary, more languages can be appended with `\DeclareCaseLangs*`.

Arguments of commands and words in braces are protected from sentence casing. To *override* this protection you have to use another pair of braces as done in the next example for the word *Blue*. Note that the second sentence is not altered because the current language at this point is German, and that language is for good reasons not in this special list; however, the third is (unconditionally), and that is wrong for German.¹

	<code>\usepackage[ngerman,english]{babel} \usepackage{biblatex}</code>
	<code>\usepackage[autostyle]{csquotes}</code>
A story of <i>Green</i> and <i>blue</i> Ducks.	<code>\MakeSentenceCase*{a Story of \emph{Green} and {\emph{Blue}}} {Ducks}.}</code>
Eine Geschichte <i>grüner</i> und <i>blauer</i> Enten.	<code>\selectlanguage{ngerman}</code>
	<code>\MakeSentenceCase*{Eine Geschichte \emph{grüner} und {\emph{blauer}}} {Enten}.}</code>
Aber „Eine geschichte ...“ ist falsch!	<code>Aber \enquote{\MakeSentenceCase{eine Geschichte \ldots}} ist falsch!</code>

16-7-32

The standard biblatex styles do not use the command; if needed, it has to be added explicitly to a format directive. Format directives are discussed in the next section — as a teaser we show how they can be used to add sentence casing to `inproceedings` entries in an author-title format.

... Southall (<i>Presentation rules and rules of composition in the formatting of complex text</i>) ...	<code>\usepackage[ngerman,english]{babel}</code>
	<code>\usepackage[style=authortitle]{biblatex}</code>
	<code>\addbibresource{t1c.bib}</code>
	<code>\DeclareFieldFormat[inproceedings]{citetitle}</code>
	<code>{\mkbibemph{\MakeSentenceCase*{#1}}}</code>
But when we switch to German, the citation changes and is no longer altered:	<code>\ldots\ \textcite{Southall} \ldots\ [3pt]</code>
... Southall (<i>Presentation Rules and Rules of Composition in the Formatting of Complex Text</i>)	<code>But when we switch to German, the citation changes and is no longer altered:\ [3pt]</code>
	<code>\selectlanguage{ngerman}\ldots\ \textcite{Southall}</code>

16-7-33

¹With \BibTeX this is a serious problem, because the styles change *all* entries if they implement sentence casing. Due to the language-awareness, biblatex does a better job as long as you have `langid` fields in your database entries set up.

16.7.16 Customizing

Customizing citations and bibliographies is not always a trivial task. Besides some \LaTeX skills, you often also need some knowledge of the underlying traditions and rules of the citation system. For example, the title of an article is often formatted differently compared to that of a book, and if the editor and translator of a work are the same person, they should appear only once. Without some understanding of the reasoning behind such settings and how they affect the coding, customization is likely to fail or may not catch all cases correctly.

Before undertaking the endeavor to adapt the code with the tools provided by `biblatex`, you should therefore check if you can achieve your aims with package or style options, by switching to another style,¹ or even by sending the style author a feature request.

The `biblatex` package offers a rather large variety of customizing commands for style authors and users:

- commands to create new citation commands or even a complete style,
- commands to declare new entry types and fields,
- commands to communicate with `biber` and for example change the sorting or the formatting of labels,
- commands to adjust the formatting of fields, punctuation, and more.

It is out of scope of this introduction to describe all of them; we therefore concentrate on a few often needed methods in user documents. If you need more, e.g., when you want to design a completely new style from scratch, consult the extensive package documentation [79].

Core configuration files and commands

We start with a short overview of the files and the main commands relevant in a style definition. Customization quite often requires you to consult or copy code from these files.

*Data models in
blx-dm.def and
.dbx files*

The default data model of `biblatex` is defined in the file `blx-dm.def`. The files declare the standard entry types, fields, and their data type and various constraints. Style authors and users can add extensions to the data model through files with the extension `.dbx`. As an example we show the declarations needed for a simple contact list: a new entry type `address` with a name field `name` and two literal fields `street` and `town`.

```
\DeclareDatamodelEntrytypes{address}
\DeclareDatamodelFields[type=list, datatype=name] {name}
\DeclareDatamodelFields[type=field, datatype=literal]{street,town}
\DeclareDatamodelEntryfields[address]{name,street,town}
```

¹For example, the `biblatex-ext` package provides variants of the standard `biblatex` styles with additional configuration options.

After these declarations, it is then possible to produce .bib files with entries such as

```
@address{beutlin-bilbo,
  name   = {Bilbo Beutlin},
  street = {1 Bagshot Row},
  town   = {Hobbiton}
}
```

Citing such entries with the standard citation commands is probably of little use with this particular entry type — you also need to declare new citation commands for this. Consult the extensive package documentation [79] for the details.

The file `biblatex.def` is an important source if you want to customize a style, because it contains many default format instructions and various definitions loaded by all styles. The file is quite long, but skimming it can serve to understand the default behavior and to find examples for own definitions.

*Standard definitions
in `biblatex.def`*

Bibliography style files with the extension .bbx contain the definitions of bibliography drivers and the definition of bibliography environments. The core command in such files is `\DeclareBibliographyDriver`.

*Bibliography
definitions in .bbx
files*

`\DeclareBibliographyDriver{entry type}{code}`

The first argument corresponds to the *entry type* used in .bib files, specified in lowercase letters. Alternatively, the argument may contain an asterisk, in which case a fallback for unknown entry types is defined. The second argument contains the *code* to typeset all bibliography entries of the type *entry type*. A .bbx file can load other .bbx files — all biblatex styles, for example, load the file `standard.bbx` that contains code common to all styles.

Citation style files with the extension .cbx contain definitions for citation commands; the main command in such files is `\DeclareCiteCommand`.

*Citation definitions
in .cbx files*

`\DeclareCiteCommand{cmd}[wrapper]{pre}{loop}{sep}{post}`

This declaration takes — besides the name of the citation command — four mandatory arguments. The *pre*-code handles the data from the pre-note argument of the citation command. The *loop*-code is executed for each key in the mandatory key-list argument of the citation command. This is the core code that prints the citation labels or any other data. The *sep*-code is executed between iterations of the *loop*-code and usually inserts some kind of separator, such as a comma or a semicolon. Finally, the *post*-code handles the post-note argument of the citation command. If the optional *wrapper* argument is given, then the entire citation is passed to it as an argument. Typical examples of wrapper commands are commands that add parentheses or put the citation into a footnote — the next example uses a font command for demonstration.

BEFORE *article1* SEP *article2* SEP *article3* AFTER

```
\DeclareCiteCommand{\citetesting}[\textit]{
  {BEFORE }{\textbf{\thefield{entrykey}}}{ SEP }{ AFTER}
\citetesting{article1,article2,article3}
```

16-7-34

Localization
definitions in .lbx
files

Localization modules are files with the extension .lbx, typically the base name of the file refers to the language it supports. They contain all language-related settings, like translations for key terms in various languages, special date formats, or adaptations to punctuation.

```
\DeclareBibliographyStrings{key/value list}
```

This is the main command in such a localization module. The *key/value list* assigns to every key term two texts, a short and a long version. Such bibliography strings can also be used with the `\bibstring` command in the pre- and postnote of citations; e.g., `\bibstring{seealso}` prints “see also” or the equivalent in another language.

```
\newbibmacro{name}[narg][default]{bib macro definition}
\usebibmacro{name} ... arguments...
```

“bibmacros”

These two commands can be found in many places in the biblatex files. The first defines a macro to be executed via `\usebibmacro` later. The syntax is very similar to `\newcommand` except that *name* may contain characters such as numbers and punctuation marks and does not start with a backslash. It can have up to nine *arguments*, and the first can be declared as being optional (if a *default* is given in the `\newbibmacro` declaration).

The underlying commands of “bibmacro” live in their own name space and do not clash with commands of other packages, and the use of non-letters has the advantage to allow more readable names; e.g., `\usebibmacro{doi+eprint+url}` quite obviously handles the doi, eprint, and url fields.

```
\printdate
\printfield[format]{field}
\printlist [format][range]{literal list}
\printnames[format][range]{name list}
\printtext [format]{text}
```

Print commands

These are some of the commands used to typeset fields and text inside citations and bibliography entries.¹ Their purpose is twofold: first, they interact with the punctuation tracker and help to avoid that missing fields lead to duplicated punctuation symbols. Second, with the exception of `\printdate`, they all apply a customizable *format* directive.

The print commands are specific to the field types as described in Section 15.3.3 on page 393 because every type has its own parsing rules that need different format definitions. If the optional *format* argument is given, it is used as the format directive.

¹There are several other `\print...` commands, but these are the important ones.

Otherwise, a directive named like the field or list in the second argument is tried; e.g., `\printnames{editor}` tries to apply the format directive named `editor` while the declaration `\printnames[myformat]{editor}` tries to apply the format directive `myformat`. If the directive `myformat` is not declared, the optional argument is ignored, and the default format directive `editor` is tried instead. If that does not exist either, no format is applied, and the field content is printed as is.

Adapting localization strings

`biblatex` offers a dedicated command to customize the language-dependent bibliography strings in a document:

```
\DefineBibliographyStrings{language}{definitions}
```

Do not confuse this command with the `\DeclareBibliographyStrings` command used in the `.lbx` files. `\DefineBibliographyStrings` has an additional argument *language*, and the *definitions* are key/value pairs that assign text to one or more identifiers but do not distinguish between a long and an abbreviated form.

The main challenge when customizing such strings is to find the identifier name(s). You can search in the `.lbx` file, but what also often works is to temporarily set the language to `nil`. `biblatex` then issues a warning about missing translations and prints the identifiers in bold. However, note that this fails sometimes. The strings `langlatin` and `langgerman` inside the `language` field are not detected, and the following example shows `byeditor` and `bytranslator` instead of `byeditortr` that is used because the editor and translator are the same person in the `cicero` entry.

References

Cicero, Marcus Tullius (1995). *De natura deorum. Über das Wesen der Götter*. langlatin **and** langgerman.
byeditor Ursula Blank-Sangmeister.
bytranslator Ursula Blank-Sangmeister.
withafterword Klaus Thraede. Stuttgart: Reclam.

```
\usepackage[nil]{babel}
\usepackage[style=authoryear]{biblatex}
\addbibresource{tlc.bib}
\AtBeginBibliography{\raggedright\small}
\nocite{cicero}
\printbibliography
```

16-7-35

In the next example we change some of the strings (not necessarily for the better). The new text should be without formatting instructions and — with exception of the language names — can be given in lowercase; it is capitalized by `biblatex` in places where that is needed.

References

Cicero, Marcus Tullius (1995). *De natura deorum. Über das Wesen der Götter*. Latin / Teutonic. Revised and adapted by Ursula Blank-Sangmeister. Addendum by Klaus Thraede. Stuttgart: Reclam.

\usepackage[english]{babel}
\usepackage[style=authoryear]{biblatex}
\addbibresource{tlc.bib}
\DefineBibliographyStrings{english}{ and = /,
  byeditortr    = revised and adapted by,
  langgerman    = Teutonic,
  withafterword = addendum by}
\nocite{cicero} \printbibliography
```

16-7-36

Customizing punctuation

In the standard styles, punctuation is typically inserted with one of two methods: as a named delimiter or as a command.

```
\setunit{\printdelim{nameyeardelim}}
\setunit{\bibpageref punct}
```

The command `\bibpageref punct` is inserted before back references: its default definition (which can be found in `biblatex.def`) is a space. It can be changed with `\renewcommand`.

The named delimiter `nameyeardelim` is — as the name implies — inserted in various places between a name and a year. Because it is inserted with the `\printdelim` command, it is context sensitive. Here “context” means things like “inside a text citation” or “inside a bibliography item”. To adapt it, a special command is provided.

```
\DeclareDelimFormat [context1,context2,...] {name}{code}
```

The first mandatory argument holds the *name* of the delimiter format being declared, the *code* argument the typeset result. With the optional argument you can restrict the applicability to certain *contexts*. These are strings such as `bib`, `biblist`, or names of citation commands without the backslash, e.g., `textcite`.

There is no easy way to distinguish which customization method is suitable for a concrete punctuation delimiter — you have to check the documentation of the style or the code to find out. In the following example we give `nameyeardelim` three different definitions and also change `\bibpageref punct` to produce \leftrightarrow .

16-7-37

Changing format directives

As discussed on page 564, the commands that are used by `biblatex` styles to print fields apply format directives. Such directives can be (re)defined with the following commands:

```
\DeclareFieldFormat [entry type1,entry type2,...] {format}{code}
\DeclareListFormat [entry type1,entry type2,...] {format}{code}
\DeclareNameFormat [entry type1,entry type2,...] {format}{code}
```

There are three separate commands to declare *format* directives for fields, lists, and names. The optional argument allows you to restrict the declaration to specific *entry*

types in the .bib file. The *code* can refer to the current field or list item with #1; for names (which are substructured) a different method is available as discussed below.

```
\citefield[pre-note][post-note]{key}[format]{field}
\citelist[pre-note][post-note]{key}[format]{literal}
\citename[pre-note][post-note]{key}[format]{name list}
```

These citation commands grant access to all lists and fields at a lower level. The optional *format* argument allows you to apply a format directive manually. This is useful to test and demonstrate formats and so we use them in the examples below.

A format directive defined with `\DeclareFieldFormat` is meant for use with `\printfield`, `\printtext`, or `\citefield`. In the *code* argument you can refer to the content of the field with #1 and to the name of the field with the command `\currentfield`.

Field formatting

In the following example we define a format directive for fields with a special formatting for articles and then apply it to some entries with the help of `\citefield`. Note that the LGC97 book entry has no volume information; thus, we get a missing field warning, and the field name is printed in bold.

```
\usepackage{biblatex} \addbibresource{tlc.bib}
\DeclareFieldFormat{myfieldformat}{\thefield{entrytype}/\currentfield/#1}
\DeclareFieldFormat{article}{myfieldformat}{\currentfield/#1}

book/volume/A \citefield{Knuth-CT-a}[myfieldformat]{volume} \\ % a book
[volume/10] \citefield{Knuth-TB10-1-31}[myfieldformat]{volume} \\ % an article
book/year/1997 \citefield{LGC97}[myfieldformat]{year} \\
volume \citefield{LGC97}[myfieldformat]{volume} % a book without volume info
```

16-7-38

A format directive defined with `\DeclareListFormat` is meant for use with `\printlist` or `\citelist`. They loop over the list items, and the current item is passed to *code* as argument #1. The item index number is available through the counter `listcount`, and the total number of items is stored in the counter `liststop`. Inside *code* you can access the name of the list with the command `\currentlist`.

List formatting

In the example we declare a new list directive and apply it to an entry with a location field with three items. Additionally, we format it with the default list directive to show the difference.

```
\usepackage{biblatex} \addbibresource{tlc-ex.bib}
\DeclareListFormat{mylistformat}
{Location \thelistcount/\theliststop: #1%
  \ifnumgreater{value{listcount}}{value{liststop}-1}%
    {!}% -- list end reached
    {,\}% -- in list
}

Location 1/3: München,
Location 2/3: Berlin,
Location 3/3: New York! \citelist{location-list}[mylistformat]{location}
München, Berlin, and New \\\[3pt]
York \citelist{location-list}{location} % default directive
```

16-7-39

Name formatting

A format directive defined with `\DeclareNameFormat` is meant for use with `\printnames` or `\citenam`. Unlike the previous declarations, it should not make use of `#1`; instead, the individual parts of a name are made available in automatically created macros. For example, the family name is provided as `\namepartfamily`, and the initials of the given name as `\namepartgiveni`.

Below we define a new name format directive and apply it to the author and editor fields of two entries from our sample database:

	<code>\usepackage{biblatex}</code>	
	<code>\addbibresource{tlc.bib}</code>	
	<code>\DeclareNameFormat{mynameformat}</code>	
	<code>{\thelistcount/\theliststop:</code>	
	<code>\namepartgiveni~\namepartfamily~(\namepartfamilyi)%</code>	
	<code>\ifnumgreater{\value{listcount}}{\value{liststop}-1}%</code>	
	<code>{\{\}\}%</code>	add a linebreak between names
	<code>}</code>	
1/3: M. Goossens (G.)	<code>\citenam{LGC97}[mynameformat]{author}</code>	<code>\\[3pt]</code>
2/3: S. Rahtz (R.)	<code>\citenam{EP92}[mynameformat]{editor}</code>	
3/3: F. Mittelbach (M.)		
1/2: C. Vanoirbeek (V.)		
2/2: G. Coray (C.)		

16-7-40

Real format directives for names are typically much more complex than field and list format directives, because they have to test for missing name parts, etc. Fortunately, there exist various predefined formats that can be used by defining alias names. This is demonstrated in the next example where we define the name format directive `mynameformat` as an alias for the predefined format `family-given`. We also apply a second predefined directive (`family-given/given-family`) directly. Compare the order of the author names in both cases.

	<code>\usepackage[giveninits]{biblatex}</code>	
	<code>\addbibresource{tlc.bib}</code>	
	<code>\DeclareNameAlias{mynameformat}{family-given}</code>	
Goossens, M., Rahtz, S., and Mittelbach, F.	<code>\citenam{LGC97}[mynameformat]{author}</code>	<code>\\</code>
Goossens, M., S. Rahtz, and F. Mittelbach	<code>\citenam{LGC97}[family-given/given-family]{author}</code>	

16-7-41

A common error when declaring format directives is to use the wrong format name. For example, `journal` is wrong because the field is mapped to `journaltitle`. The title in an author-title citation uses the `citetitle` format directive, and the authors in the bibliography in an author-date style use the directive `sortname`. Another source of error is that some default format directives are entry type specific: to overwrite them one has to declare them for the specific type. For example, in Example 16-7-33 on page 561 we had to change the format specifically for `inproceedings` to overwrite the `biblatex` default. The same would be the case for the title of an article.

As a final example we change the default order of the author names in the bibliography by adapting the `sortname` format. We also show how to change the font of the names to small caps by redefining the wrapper commands like `\mkbibnamefamily` and `\mkbibnamegiven` used by `biblatex` around the name parts. We place everything

into the hook `\AtBeginBibliography` to restrict the font changes to the bibliography and not affect the names in citation references.

16.8 Multiple bibliographies in one document

In large documents that contain several independent sections, such as conference proceedings with many different articles, or in a book with separate parts written by different authors, it is sometimes necessary to have separate bibliographies for each of the units. In such a scenario citations are confined to a certain part of the document, the one to which the bibliography list belongs.

A complementary request is to have several bibliographies in parallel, such as one for primary sources and one for secondary literature. In that case one has to be able to reference works in different bibliographies from any point in the document.

Both requests can be easily resolved when using the `biblatex` package. It has extended capabilities to print multiple bibliographies filtered and sorted by various conditions or to restrict their scope to parts of a document. This is described in Sections 16.7.8 to 16.7.10.

If using `biblatex` is not an option, both requests can also be automatically resolved if none of the bibliographies contains the same publication¹ and you are prepared to produce the bibliographies manually by means of several `thebibliography` environments without using `BIBTEX`. In that case the `\bibitem` commands within the environment provide the right cross-referencing information for the `\cite` commands (or their variants) to pick up from anywhere in the document. Having the same publication in several bibliographies (or more exactly the same reference key) is not possible, because that would lead to a “multiply defined labels” warning (see page 761) and to incorrect references. Of course, this could be manually corrected by choosing a different key for such problematical citations.

Being deprived of using `BIBTEX` or `biblatex/biber` has a number of consequences. First, it is more difficult to impose a uniform format on the bibliographical entries (something that the bibliography processors automatically handles for you). Second,

¹This could happen, for example, if you compile the proceedings of a conference and each article therein has its own bibliography.

	Bibliographies per Unit

	Per Topic				

Blue entries indicate features (or missing features) that may force a selection.

^aOnly if `\include` is used. The option `duplicate` gives warnings about duplicate destinations; the links go from the citation to the first bibliography. ^bActive links only when `natbib` is used too. Entries present in more than one bibliography give warnings about duplicate destinations; the links go to the first bibliography.

^c`\newcites` should be issued after `\usepackage{hyperref}`.

Table 16.3: Comparison of packages for multiple bibliographies

using an author-date or short-title citation scheme is difficult (because `natbib` requires a special structure within the optional argument of `\bibitem`) to downright impossible (because the structure required by `jurabib` or `biblatex` is not suitable for manual production); see Section 16.3 and 16.7 for a discussion of the required `\bibitem` or `.bbl` structures in those cases.

To be able to use `BIBTEX` for this task people had to find a way to generate several `.bbl` files from one source document. As discussed in Section 15.4, the interaction with `BIBTEX` normally works as follows: each citation command (e.g., `\cite`) writes its *key-list* as a `\citation` command into the `.aux` file. Similarly, `\bibliography` and `\bibliographystyle` commands simply copy their arguments to the `.aux` file. `BIBTEX` then reads the master `.aux` file (and, if necessary, those from `\included` files) searching for occurrences of the above commands. From the provided information it produces a single `.bbl` file. To make `BIBTEX` work for the above scenarios, four problems have to be solved:

1. Generate one `.aux` file for every bibliography in the document that can be used as input for `BIBTEX`.

2. Ensure that each citation command writes its information to the correct `.aux` file so that BibTeX, when it processes a given `.aux` file, adds the corresponding bibliographical data in the `.bbl` file but not in the others.
3. Ensure that the resulting `.bbl` files are read back into L^AT_EX at the right place.
4. Handle the problem of escaping citations due to their placement in sectioning or `\caption` commands. A citation in such a place would later appear in the table of contents or list of figures, and there (in a different context) L^AT_EX would have problems in resolving it.

The packages `chapterbib`, `bibunits`, `bibtopic`, and `multibib`, which are described in this section, solve the above problems in different ways. They all have their own advantages and disadvantages. A short comparison of these packages appears in Table 16.3 on the preceding page, where blue entries indicate features (or missing features) that may force a selection when one is looking for a solution for bibliographies per unit or with bibliographies per topic, or a combination of both.

16.8.1 chapterbib — Bibliographies per included file

The `chapterbib` package (developed by Donald Arseneau based on original work by Niel Kempson) allows multiple bibliographies in a L^AT_EX document, including the same cited items occurring in more than one bibliography.

It solves the problem of producing several `.aux` files for BibTeX, by relying on the `\include` mechanism of L^AT_EX; you can have one bibliography per `\included` file. This package can be used, for example, to produce a document with bibliographies per chapter (hence the name), where each chapter is stored in a separate file that is included with the `\include` command. This approach has the following restrictions:

- Each `\include` file needs to have its own `\bibliography` command. The database files that are listed in the argument can, of course, be different in each file. What is less obvious is that each file must contain a `\bibliographystyle` command, though for reasons of uniformity *preferably with the same style argument* (Example 16-8-1 on the following page shows that different styles can be applied).
- The `.aux` files of each `\include` file are processed individually by BibTeX. This means that *independent* bibliographies and labels are generated for each unit and that the same work can have differing labels in the units or two different works can have the same label; see also the discussion about the “reference sections” from the `biblatex` package in Section 16.7.10 on page 556.
- An `\include` file not containing a `\bibliography` command cannot contain citation commands, because they would not get resolved.
- Citation commands outside of `\include` files (with the exception of those appearing in the table of contents; see below) are not resolved, unless you include a `thebibliography` environment on that level. Without special precautions, this environment has to be entered manually. If you use BibTeX on the

document's .aux file, you will encounter errors, because BibTeX sees multiple `\bibdata` and `\bibstyle` commands (when processing the included .aux files). In addition, you get *all* citations from *all* `\include` files added, and that is perhaps not desirable. If you do want a cohesive bibliography for the whole document, there is a `rootbib` option to help with this task. However, it requires adding and removing the option at different stages in the process; see the package documentation for details.

- Units containing a local bibliography always start a new page (because of the `\include` command). For cases where this is not appropriate, `chapterbib` offers some support through a `\cbinput` command and `cbunit` environment¹; see the package documentation for details. Unless you need the `gather` option, it might be better to use the `bibunits` package in such situations.

By default, the `thebibliography` environment generates a numberless heading corresponding to the highest sectioning level available in the document class (e.g., `\chapter*` with the `book` class). However, if bibliographies are to be generated for individual parts of the document, this may not be the right level. In that case you can use the option `sectionbib`² to enforce `\section*` headings for the bibliographies.

In the following example, we present the `\include` files `article-1.tex` and `article-2.tex` in `filecontents` environments, which allows us to process this example automatically for the book. In real life these would be different files on your computer file system. We also use `\stepcounter` to change the `chapter` counter rather than using `\chapter` to avoid getting huge chapter headings in the example. Note that both included files refer to a publication with the key `Knuth-CT-a`. These are actually treated as different keys in the sense that one refers to the publication from `article-1.bbl` and the other refers to that from `article-2.bbl`.

```

16-8-1

¹`cbunit` can be used only together with manual `thebibliography` environments.

²If both `chapterbib` and `natbib` are used, use the `sectionbib` option of `natbib` instead!

If you wish to group all the bibliographies together (for example, at the end of the document), use the option `gather` and place a `\bibliography` command at the point where the combined bibliography should appear.¹ The argument of that command can be left empty because it is not used to communicate with `BBTeX`.

Instead of `gather`, you may want to use the option `duplicate`. It produces “chapter bibliographies”, plus the combined listing. Both options work with the default settings only in document classes that have a `\chapter` command. The headings for each subbibliography generated by either option can be customized by redefining the command `\FinalBibTitles`. As you can see, you can make use of commands inside its definition, e.g., `\thechapter` and `\chaptitle` in the example. By altering their values (either implicitly or explicitly) before including the articles, different sub-bibliographies get different headings as shown below:

```
% Included files as in previous example
\usepackage [gather,sectionbib]{chapterbib}
\newcommand\FinalBibTitles{References for Article-\thechapter
~\mbox{---}~\chaptitle}

\newcommand\chaptitle{Intro}      \include{article-1}
\renewcommand\chaptitle{Summary} \include{article-2} \bibliography{}
```

Bibliography

16-8-2

If the highest heading unit in your document is `\section`, you can redefine `\StartFinalBibs`. This gives you more control, but is a bit more complicated to set up: you can then use `\refname` in the main sectioning but should also redefine `\bibname` to `@auto@bibname` for the headings of the subbibliographies; for details refer to the package documentation. In the following example we include slightly changed files that step the section counter instead of the chapter counter.

*Using documents
with \section as
highest level*

```
% Included files as before (i.e., from Example 16-8-1), but
% this time we are stepping the section counter.
\usepackage [gather]{chapterbib}
\sectionbib{\subsection*}{subsection}
```

¹ It should be placed after all units whose bibliography it should show.

```

\newcommand\FinalBibTitles{References for Article \thesection}
\renewcommand\StartFinalBibs{\section*{\refname}%
\begingroup
\setcounter{secnumdepth}{-1}%
\addcontentsline{toc}{section}{\refname}%
\sectionmark{\refname}%
\endgroup
\renewcommand\bibname{\UseName{@auto@bibname}}}

\include{article-1} \include{article-2} \bibliography{

16-8-3

If citations are placed into sectioning or `\caption` commands, they appear eventually in some table of contents list (i.e., at the top level). Nevertheless, `chapterbib` properly resolves them, by inserting extra code into `.toc`, `.lof`, and `.lot` files so that a `\cite` command is able to determine to which local bibliography it belongs. If you have additional table of contents lists set up, as explained in Section 2.3.4, you have to be careful to avoid citations that may end up in these new contents lists, because `chapterbib` is unaware of them.

Command
already defined
error

Some BibT_EX styles unfortunately use `\newcommand` declarations instead of `\providecommand` in the generated `.bbl` files, which makes such files unsuitable for repeated loading. If you get “Command *<name>* already defined” errors for this reason, surround the `\bibliography` commands and their arguments in braces. For example, write

```
{\bibliography{t1c}}
```

The `chapterbib` package is compatible with most other packages, including the citation packages discussed earlier in this chapter. If you plan to use it together with `babel`, load the `chapterbib` package first.

16.8.2 bibunits — Bibliographies for arbitrary units

The `bibunits` package developed by Thorsten Hansen (from original work by José Alberto Fernández) generates separate bibliographies for different units (parts) of the text (chapters, sections, or `bibunit` environments). The package separates the

citations of each unit of text into a separate file to be processed by \LaTeX . A global bibliography can also appear in the document, and citations can be placed in both at the same time.

```
\begin{bibunit}[style] ... \putbib[file-list] ... \end{bibunit}
```

One way to denote the units that should have a separate bibliography is by enclosing them in a `bibunit` environment. The optional parameter `style` specifies a style for the bibliography different from a default that may have been set up (see below). Instead of `\bibliography`, you use a `\putbib` command to place the bibliography. It can appear anywhere within the unit as proven by the example. The optional argument `file-list` specifies a comma-separated list of \LaTeX database files; again a default can be set up. A default \LaTeX style can be set with `\defaultbibliographystyle`; without it, `plain` is used as the default. Similarly, `\defaultbibliography` can be used to define a default list of \LaTeX databases. In its absence `\jobname.bib` is tried. The example below uses both methods (explicit and defaults).

Setting up defaults

\ldots
\putbib % default used
\end{bibunit}
```

16-8-4

For each unit `bibunits` writes the `\citation` commands (used to communicate with \LaTeX) into the file `bu⟨num⟩.aux`, where `⟨num⟩` is an integer starting with 1. Thus, to generate the necessary bibliographies, you have to run \LaTeX on the files `bu1`, `bu2`, and so forth. As a consequence, with the default settings you cannot process more than one document that uses `bibunits` in the same directory, because the auxiliary files would be overwritten.¹ After generating the bibliographies, you have to rerun \LaTeX at least twice to resolve the new cross-references.

A global bibliography, in addition to the bibliographies for the individual units, can be generated by using `\bibliography` and `\bibliographystyle` as usual. Outside of a `bibunit` environment, the standard commands should be used to generate a citation for the global bibliography. Inside `bibunit`, use `\cite*` and `\nocite*` instead of `\cite` and `\nocite` to generate a citation for both the local

¹If necessary, you can direct the package to use different names; see the package documentation.

and the global bibliography. There are, however, a number of restrictions. If the `natbib` package is also loaded, then `\cite*` has the meaning defined by `natbib` and cannot be used for generating a global citation (use `\nocite` outside the unit in that case). In addition, refrain from using numerical citation labels, because they are likely to produce ambiguous labels in the global bibliography, as shown in the next example. A better choice would be a \LaTeX style such as `alpha`.

\bibliography{tlc}
```

16-8-5

Rather than using `\cite*` everywhere in your document, you can specify the package option `globalciterecopy`. All local citations are then automatically copied to the global bibliography as well.

`\bibliographyunit[unit]`

Instead of specifying the bibliography units with `bibunit` environments explicitly, you can specify the sectioning unit for which bibliography units should be generated automatically. The `\bibliographyunit` command defines with its optional argument for which document *unit* references must be generated, e.g., `\chapter` (for each chapter) or `\section` (for each section). If the optional argument is not given, the command deactivates further bibliography units. When `\bibliographyunit` is active, the `\bibliographystyle` and `\bibliography` commands specify the \LaTeX files and the style to be used by default for a global bibliography, as well as in the local units. If you wish to specify information for local bibliographies only, use `\bibliography*` and `\bibliographystyle*` instead. These declarations *cannot* be used in the preamble but must be placed after `\begin{document}`.

Getting
unresolved
references

There is, however, a catch with the approach: the normal definition of the `thebibliography` environment, which surrounds the reference lists, generates a heading of the highest sectioning level. Hence, if you use `\chapter` units in a report, the heading generated by that environment prematurely ends the unit, and

consequently you end up with undefined references, as shown in the example (using `\section` units in an article class).

\putbib
\section{Another one}
As described by
\cite{aschur} \ldots
\putbib
```

To resolve this problem, you can provide your own `thebibliography` environment definition so that it uses a different sectioning level than the one specified on the `\bibliographyunit` declaration. Alternatively, you can use the option `sectionbib` (use `\section*` as a heading in `thebibliography`) or `subsectionbib` (use `\subsection*`) to change the `thebibliography` environment for you.

\cite{aschur} \ldots
\putbib
```

Note that the unit specified on the `\bibliographyunit` command has to be different from the one referred to in the option. In the above example the unit was `\section`, so we used the `subsectionbib` option.

To resolve the problem of escaping citations (see page 571), the package offers the option `labelstoglobalaux`. However, this has the side effects that such citations appear in the global bibliography and that numerical reference schemes are likely to produce incorrect labels; see the package documentation for details.

16.8.3 bibtopic — Combining references by topic

In contrast to `chapterbib` and `bibunits`, which collect citations for individual units of a document, the package `bibtopic` written by Stefan Ulrich (based on earlier work by Pierre Basso) combines reference listings by topic. You can, for example, provide a primary reference listing separate from a reference list for further reading or put all references to books separate from those to articles.

Within the document all citations are produced with `\cite`, `\nocite`, or variants thereof (if `natbib` or similar packages are also loaded). Thus, separation into topics is handled at a later stage. To produce separate bibliographies by topic you have to group the bibliographical entries that belong to one topic in a separate `BIBTEX` database file (e.g., one for primary sources and one for secondary literature). The bibliographies are then generated by using several `btSect` environments. Ways to generate separate database files are described in Section 15.6: e.g., reference managers and also `biber` can be used to extract entries. Another option to extract reference entries according to some criteria from larger `BIBTEX` database collections is the program `bibttool` developed by Gerd Neugebauer. It is distributed as a C source file, though you may find precompiled binaries — for example, in the Debian and FreeBSD distribution families.

```
\begin{btSect}[style]{file-list}
```

The `btSect` environment generates a bibliography for all citations from the whole document that have entries in the `BIBTEX` database files listed in the comma-separated *file-list* argument. If the optional *style* argument is present, it specifies the `BIBTEX` style to use for the current bibliography. Otherwise, the style specified by a previous `\bibliographystyle` declaration is used. If no such declaration was given, the `BIBTEX` style `plain` is used as a default.

Unless the package was loaded with the option `printheadings`, the environment produces no heading. Normally, you have to provide your own heading using `\section*` or a similar command.

```
\btPrintCited    \btPrintNotCited    \btPrintAll
```

Within a `btSect` environment one of the above commands can be used to define which bibliographical entries are included among those from the specified *file-list* databases. The `\btPrintCited` command prints all references from *file-list* that have been somewhere cited in the document, `\btPrintNotCited` prints those that have not been cited, and `\btPrintAll` prints all entries in the `BIBTEX` database files.

The following example shows the basic concepts using two topics: “`TEX` related” and “juridical” literature; it uses the databases `tlc-tex.bib` and `tlc-jura.bib` in which we copied some entries from our standard database. The first bibliography uses the default `plain` style; for the second bibliography we explicitly specified the `BIBTEX` style `abbrv` (this is meant as an illustration — mixing styles is usually a bad idea). As you can see, if you specify numerical `BIBTEX` styles, `bibtopic` automatically

uses consecutive numbers throughout all bibliographies to ensure that the references in the document are unique.

We saw the citations [3], [2], and [1].

\TeX literature

- [3] D. E. Knuth. *The \TeX book*, volume A of *Computers and Typesetting*. Addison-Wesley, Reading, MA, USA, 1986.

```
\usepackage{bibtopic}
```

```
We saw the citations \cite{Knuth-CT-a},
\cite{aschur}, and \cite{bschur}.
```

```
\begin{btSect}{tlc-jura}
  \section*{Juridical literature}
  \btPrintCited
```

```
\end{btSect}
```

```
\begin{btSect}[abbrev]{tlc-tex}
  \section*{\TeX{} literature}
  \btPrintCited
```

```
\end{btSect}
```

16-8-8

For every `btSect` environment, the `bibtopic` package generates a separate `.aux` file that by default is constructed from the base name of the source document (`\jobname`) and a sequence number. You can change this naming scheme by redefining `\thebtauxfile` using the counter `btauxfile` to automatically obtain a sequence number. For the book examples we used the following redefinition:

```
\renewcommand\thebtauxfile{\jobname+\arabic{btauxfile}}
```

The `bibtopic` package is incompatible with `chapterbib` and `bibunits`. However, it provides the environment `btUnit` to confine the citations to logical units. Within such units the `btSect` environment can be used in the normal way, allowing for topic bibliographies by chapter or other unit. In that case *all* citations have to appear within such units (escaping citations, discussed on page 571, are not handled, so you have to ensure that they do not happen). By default, numerical styles restart their numbering per unit (e.g., per article in a proceedings issue). If you want continuous numbering, use the option `unitcntnoreset`.

*Bibliographic topics
per logical unit*

While `bibtopic` works with most \LaTeX styles, there are some exceptions. The most important one is that it does not work as expected with “unsorted” styles (e.g., `unsorted`). If such a style is used, then the order in the bibliography is determined by the order in the \LaTeX database file and *not* by the order of citation in the document. If the latter order is required, you should use the `multibib` package described in the next section.

*Problem with
nonsorting \LaTeX
styles*

The `bibtopic` package is compatible with most other packages that provide extensions to the citation mechanism, including `cite`, `natbib`, and `jurabib`. There are, however, some restrictions with respect to the production of the bibliography lists. For example, hooks to influence the layout as provided by `natbib` or `jurabib` may not be functional. Details are given in the package documentation.

Here is a repeat of Example 16-8-8 but using jurabib this time:

16-8-9

16.8.4 multibib — Separate global bibliographies

Like bibtopic, the multibib package written by Thorsten Hansen provides separate global bibliographies. While the former package separates the bibliographies by using separate B_BT_EX database files, multibib works by providing separate citation commands to distinguish citations in different bibliographies.

There are advantages and disadvantages with either method. With multibib, different types of citations are clearly marked already in the source document. As a consequence, however, moving a citation from one bibliography to a different one in a consistent manner requires changes to the document in various places. In contrast, with bibtopic it merely requires moving the corresponding database entry from one file to another. On the other hand, bibtopic often requires tailored .bib files for each new document, while with multibib one can use generally available collections of B_BT_EX database files.

The multibib package is compatible with most other packages that provide extensions to the cite mechanisms, including cite, jurabib, and natbib. Moreover, the package provides a general interface, which allows adding arbitrary extensions of cite commands to be recognized by multibib.

```
\newcites{type}{title}
```

The `\newcites` declaration defines an additional set of citation commands for a new *type* of citations. The heading for the additional bibliography listing is *title*. Once this declaration is given, the four additional commands are available for use. The command `\cite{type}`, like `\cite`, generates a citation within the text, and its corresponding reference appears in the bibliography listing for the new *type*. Similarly, `\nocite{type}` adds a citation to the *type* bibliography without appearing in the text. The corresponding bibliography appears at the point where

the `\bibliography{type}` command is given, and the BibTeX style used for this bibliography is defined with `\bibliographystyle{type}`. An example is shown below.

A book on graphics in L^AT_EX is [1]; suggestions on citations can be found in [vL92].

L^AT_EX references

- [1] Michel Goossens, Sebastian Rahtz, and Frank Mittelbach. *The L^AT_EX Graphics Companion: Illustrating Documents with T_EX and PostScript*. Tools and Techniques for Computer Typesetting. Addison-Wesley Longman, Reading, MA, USA, 1997.

General references

- [vL92] Mary-Claire van Leunen. *A handbook for scholars*. Oxford University Press, Walton Street, Oxford OX2 6DP, UK, 1992.

```
\usepackage{multibib}
\newcites{latex}
{\LaTeX{} references}
```

A book on graphics in \LaTeX{} is \citelatem{LGC97}; suggestions on citations can be found in \cite{vLeunen:92}.

\bibliographylatex{tlc}
```

```
\renewcommand\refname
{General references}
\bibliographystyle{alpha}
\bibliography{tlc}
```

16-8-10

The `\newcites` declaration can be used several times, thereby creating additional citation types. It is limited only by the number of output files that can be used simultaneously by T_EX. The .aux file written for communication with BibTeX has the name `<type>.aux`. For this reason one has to be a bit careful when selecting the *type* in the first argument to `\newcites`, to avoid overwriting other .aux files.

For numerical citation styles the references are by default numbered sequentially over all bibliographies to avoid ambiguous references. When using the option `resetlabels`, each bibliography restarts the numbering.

L^AT_EX offers an interface to include graphics.¹ L^AT_EX's default citation scheme is number-only.²

CHAPTER 17

L^AT_EX Package Documentation Tools

17.1 doc — Documenting L ^A T _E X and other code	584
17.2 docstrip.tex — Producing ready-to-run code.	599
17.3 l3build — A versatile development environment	606
17.4 Making use of version control tools	615

In this chapter we describe the `doc` system, a method to document L^AT_EX macros and environments. A large proportion of the L^AT_EX code available is documented using its conventions and support tools. The underlying principle is that L^AT_EX code and comments are mixed in the same file and that the documentation or the stripped package file or files are obtained from the latter in a standard way. In this chapter we explain the structure that these files should have and show how, together with the program `DOCSTRIP`, you can build self-installing procedures for distributing your L^AT_EX packages and generating the associated documentation. The chapter also helps you understand the code written by others, install it with ease, and produce the documentation for it (not necessarily in that order).

The third section then introduces the `l3build` program, which offers a flexible development environment. It supports a package developer in all important steps: code and documentation development, testing, and all aspects of the release management including upload to CTAN. It is the workflow environment used by the L^AT_EX Project Team for the code that they manage.

We end the chapter with a section on version control systems and explain how to extract and use their information with L^AT_EX. Applying version control methods is definitely useful for any larger documentation project, but in fact is advisable for any document that goes through a number of “revisions”.

17.1 doc — Documenting L^AT_EX and other code

The idea of integrated documentation was first employed by Donald Knuth when he developed the T_EX program using the WEB system, which combines Pascal-like meta source code and documentation. Thanks to his approach, it was particularly easy to port T_EX and its companion programs to practically any computer platform in the world.

Subsequently, authors of L^AT_EX packages started to realize the importance of documenting their L^AT_EX code. Many now distribute their L^AT_EX macros using the framework defined with the `doc` package (by Frank Mittelbach) and its associated `DOCSTRIP` utility (originally by Frank Mittelbach with later contributions by Johannes Braams, Denys Duchier, Marcin Woliński, and Mark Wooding).

The `doc` package was written roughly 30 years ago (version 1 appeared in 1988, predating L^AT_EX 2_ε). Since then it has been extensively used to document the L^AT_EX kernel and most of the packages that are available on today's L^AT_EX distributions. The core code of version 2 has existed since 1998, and that version was distributed with L^AT_EX until 2022. At the TUG conference in Rio 2018 the author sketched out plans for a version 3 to improve it in several respects, but given it is so widely used, any change would need to be very light-weight, basically adding hyperlink support and adding a way to provide additional `doc` elements (not just macros and environments), with full compatibility to support all the existing uses.¹

Both systems together allow L^AT_EX code and documentation to be held in the same T_EX source file. The obvious advantage is that a sequence of complex T_EX instructions becomes easier to understand with the help of comments inside the file. In addition, updates are more straightforward because only a single source file needs to be changed.

The `doc` package provides a set of commands and establishes some conventions that allow specially prepared source files to contain both code and its documentation intermixed with each other. This is discussed in Sections 17.1.1 to 17.1.3.

To produce the documentation you need a driver (file) that loads the `doc` package and then interprets the source file. In its simplest form the driver for the documentation is an external file. However, the driver is more commonly made part of the source file so that all you have to do to produce the documentation is to run the source file through L^AT_EX. The possibilities are discussed in detail in Section 17.1.4.

To produce a ready-to-run version of your code you need to first process the source package with `DOCSTRIP` (see Section 17.2). This step is usually implicitly done by providing an `.ins` file that is run through L^AT_EX. The most important commands and concepts are discussed in the next sections. Tables 17.1 to 17.5 on pages 595–597 provide an overview of all `doc` user commands. Further details on any of them can be found in the documented source `doc.dtx` of the `doc` package, which can also serve as a prime (though somewhat aged) example of the `doc` system.

¹If I restarted from scratch, I would do a lot of things differently now, and in fact several other people have tried to come up with better solutions. However, as the saying goes, a bad standard is better than none, so `doc` has prevailed, and changing it now in incompatible ways would be a nonstarter. Some of the ideas for the extensions have been borrowed from Didier Verna's `DoX` package, even though I did not use the document-level interfaces.

17.1.1 General conventions for the source file

A L^AT_EX file to be used with the doc system consists of *documentation parts* intermixed with *code parts*. Every line of a documentation part starts with a percent sign (%) in the first column. It can contain arbitrary T_EX or L^AT_EX commands, but the % character cannot be used as a comment character. User comments are created by using the ^^A character or, if you prefer, the ^^X character instead. Longer text blocks can be turned into comments by surrounding them with %\iffalse ... %\fi. All other parts of the file are called code parts. They contain the code described in the documentation parts.

Depending on how the code parts are structured, it is possible to use such a file directly with L^AT_EX, although these days this is seldom done. Instead, DOCSTRIP is typically used to produce the production files. If the former approach is taken, L^AT_EX bypasses the documentation parts at high speed and pastes the macro definitions together, even if they are split into several code parts.

On the other hand, if you want to produce the documentation of the macros, then the code parts should be typeset verbatim. This is achieved by surrounding these parts by the macrocode environment.

```
%\begin{macrocode}
  <one or more lines of code>
%\end{macrocode}
```

It is mandatory that you put *exactly* four spaces between the % character and \end{macrocode} and no space between \end and its argument. The reason is that when L^AT_EX is processing the macrocode environment, it is actually looking for that particular string and not for the command \end with the argument macrocode.

Inside a code part all T_EX commands are allowed. Even the percent sign can be used to suppress unwanted spaces at the ends of lines.

If you prefer, you can use the macrocode* instead of the macrocode environment. It produces the same results except that spaces are displayed as □ characters when the documentation is printed.

17.1.2 Describing new macros and environments

Most packages contain commands and environments to be employed by users in their documents. To provide a short manual describing their features, a number of constructs are offered by the doc package.

```
\DescribeMacro [keys] { \cmd1, ... } \Describe(element) [keys] { entry1, ... }
```

The \DescribeMacro command takes one argument containing a comma-separated list of command names, which are shown in the margin, and for which special (usage) index entries are generated, for example,

```
% \DescribeMacro{\DocInput,\IndexInput}
% Finally the \meta{input commands} part ...
```

In the optional argument you can specify either `noindex` or `noprint` to suppress indexing or printing for that particular instance. Using both would be possible too, but pointless because then the command would do nothing.

A similar command, `\DescribeEnv`, can be used to indicate that at this point one or more L^AT_EX environments are being explained, and if you declare additional doc elements, e.g., `\element`, then `\Describe $\langle element \rangle$` becomes available too.

```
\begin{macro}[keys]{\cmd1,...,\cmdn}
\begin{environment}[keys]{env1,... ,envn}
```

To describe the definition of one or more commands, you use the `macro` environment. It takes one mandatory argument: a comma-separated list of the new commands. This argument is also used to print the names in the margin and to produce appropriate index entries. The index entries for usage (produced by `\Describe...`) and for definition are different, which allows for easy reference. Here is an example taken from the sources of the `doc` package itself:

```
% \begin{macro}{\check@angle}
%   Before looking ahead for the |<| the |%| is gobbled by the
%   argument here.
%   \begin{macrocode}
\def\check@angle#1{\futurelet\next\ch@angle}
%   \end{macrocode}
% \end{macro}
```

The optional `keys` argument lets you suppress indexing or printing of the command names in the margin, through specifying either `noindex` or `noprint` for that particular instance. If any such setting is made on the environment level, it overwrites whatever default was given when the `doc` element was defined or when the package was loaded.

By default the commands listed in the mandatory argument of the `macro` environment are not allowed to be declared with `\outer` (which is a plain T_EX concept not officially supported by L^AT_EX). However, should you really want to document such a command, you can do so by specifying the key `outer` in the optional `keys` argument.

Another environment, with the unimaginative name `environment`, documents the code of environments. It works like the `macro` environment but expects the name or names of environments as its argument.

These two (`macro` and `environment`) are the `doc` elements supported out of the box by the package. How to define further elements is covered in Section 17.1.6 on page 592.

```
\MakeShortVerb{\c}   \MakeShortVerb*{\c}   \DeleteShortVerb{\c}
```

When you have to quote a lot of material verbatim, such as command names, it is awkward to always have to type `\verb+...+`. Therefore, the `doc` package provides an abbreviation mechanism that allows you to pick a character `c`, which you plan to use

only very rarely inside your document, to delimit your verbatim text — the character " is often chosen, but if that character is already used for another purpose, such as for shorthands in `babel`, then you may prefer `|` or some other character. Then, after including the command `\MakeShortVerb{\c}`, the sequence `c text c` becomes the equivalent of `\verb c text c`.

The variant form `\MakeShortVerb*` does the same but uses `\verb*`. If you later want to use `c` with its original meaning, just type `\DeleteShortVerb{\c}`. You can repeat this sequence using `c` as a shorthand for `\verb` and reverting to its original meaning as many times as needed.¹ Note that such short forms for `\verb`, just like `\verb` itself, cannot appear in the argument of another command, but the characters may be used freely inside `verbatim` and `macrocode` environments.

You can divide your documented package file into two parts, the first typically containing a general description and the second giving a detailed description of the implementation of the macros. When generating the document, you can suppress this latter part if you place the command `\MaybeStop` at the division point between the two parts.²

<code>\MaybeStop{final text}</code>	<code>\Finale</code>
-------------------------------------	----------------------

The `\MaybeStop` macro takes one argument in which you put all the information that you want to see printed if the user decides to stop typesetting the document at that point (for example, a bibliography, which is usually printed at the end of the document). When the driver file contains an `\OnlyDescription` declaration, L^AT_EX processes the argument of `\MaybeStop` and then stops reading the file. Otherwise, the `\MaybeStop` macro saves its argument in a macro called `\Finale`, which can later be used to get things back (usually at the very end). This scheme makes changes in two places unnecessary. The default is to typeset the whole document. This default can also be explicitly set by using the `\AlsoImplementation` command in the preamble.

A simple scheme to provide both user documentation and full documentation including the code part is to provide a driver as part of the package `.dtx` file with an `\OnlyDescription` in its preamble and then offer a second file with the name `<package>-code.tex` that just contains the lines such as:

```
\AtBeginDocument{\AlsoImplementation} % force full documentation
\input{doc.dtx}                        % load the package .dtx
```

You could alternatively use two such files, i.e., `<package>-code.tex` for the code documentation and `<package>-doc.tex` for the user interface, which is also often done.

¹This feature has also been made available as a stand-alone package, `shortvrb`; it was discussed in Section 4.2. See Example 4-2-3 on page 298.

²For a long time this command was called `\StopEventually` (still supported because it is used all over the place in older documentation). The slightly strange command name was due to a “false friend”: the German word for ‘perhaps’ is ‘eventuell’, and when the author found out it was not saying what he thought it was, it had been in use for years without anybody telling him.

`\changes{version}{date}{text}`

To document the change history, the `\changes` command can be placed within the description part of the changed code. The information in the `\changes` command may be used to produce an auxiliary file (L^AT_EX's `\glossary` mechanism is used for this purpose), which can be printed after suitable formatting. To cause the change information to be written, include `\RecordChanges` in the driver file. To read and print the sorted change history, put the `\PrintChanges` command at a suitable point, typically after the `\PrintIndex` command in the driver.

To generate the sorted file containing the changes, you should run the raw glossary file through *MakeIndex* using an adequate style (like `gglo.ist`, supplied with the doc distribution; see Section 14.1.6 on page 349 for more information about how *MakeIndex* treats glossaries).

17.1.3 Cross-referencing all macros used

Inside a `macrocode` or `macrocode*` environment, index entries are produced for every command name that starts with a backslash. In this way you can easily find out where a specific macro is used. Since T_EX works considerably more slowly when it has to produce such an array of index entries, you can turn off this feature by using `\DisableCrossrefs` in the driver file. To turn it on again, use `\EnableCrossrefs`.

Finer control is provided with the `\DoNotIndex` command, which takes one argument containing a comma-separated list of commands that are *not* to be entered in the index. More than one `\DoNotIndex` command can be present, in which case their contents are combined. A frequent use of this macro is to exclude native L^AT_EX commands from the index.

`\DisableCrossrefs`, `\EnableCrossrefs`, and `\DoNotIndex` can be used in the document body. They obey the current grouping, which allows you, for example, to turn off indexing within a specific macro environment without the need to explicitly restart it afterwards.

The overall production (or not) of index entries is controlled by using or omitting the following declarations in the driver file preamble (if no declaration is provided, no index is produced). Using `\PageIndex` makes all index entries refer to their page number. With `\CodelineIndex`, index entries produced by `\DescribeMacro` and `\DescribeEnv` refer to the relevant page numbers, but those produced by the `macro`, `environment`, and `macrocode` environments refer to the code lines, which are numbered automatically. If you have defined your own environments with `\NewDocElement`, then they exhibit the same behavior.

If index entries are produced, they have to be sorted by an external program, such as *MakeIndex* (see Chapter 14). The `doc` package uses special conventions for the index entries, so you need to run *MakeIndex* with the `-s` switch (see Section 14.2.4 on page 356) to specify a suitable style — for example, `gind.ist`, which is distributed with the `doc` system.

To read and print the sorted index, you must put the `\PrintIndex` command near the end of your driver file, possibly preceded by bibliography commands, as

needed for your citations. If you do not want to produce an index but you want the code lines numbered nevertheless, you can use the declaration `\CodelineNumbered` in the preamble.

17.1.4 The documentation driver

To get the documentation for a set of macros with the doc system, you have to prepare a driver (file) with the following characteristics:

```
\documentclass[⟨class options⟩]{⟨document-class⟩}
\usepackage[⟨package options⟩]{doc}
⟨preamble⟩
\begin{document}
  ⟨input-commands⟩
\end{document}
```

The `⟨document-class⟩` may be any legal class, such as `article` or `ltxdoc` (described in Section 17.1.9); in the latter case the `doc` package is already loaded by the class. In the `⟨preamble⟩`, you should place declarations that manipulate the behavior of the doc system, such as `\DisableCrossrefs`, `\OnlyDescription`, and `\CodelineIndex`. Finally, the `⟨input-commands⟩` part should contain one or more `\DocInput` and/or `\IndexInput` commands.

```
\DocInput{file name}    \IndexInput{file name}
```

The `\DocInput` command is used for files prepared for the doc system, whereas `\IndexInput` can be used for macro files that do not obey the conventions of the doc system. The latter command takes a file name as its argument and produces a verbatim listing of the file, indexing every command as it goes along. This functionality can be handy if you want to learn something about macros without enough documentation.

It is also possible to use the `\PrintIndex` and `\PrintChanges` (if the changes are recorded by `\RecordChanges`) commands. Some people put them directly into the source file, but it is better practice to place them into the driver. You can then combine several packages in one document and produce a combined index.

As mentioned in the introduction, most often the driver is included directly in the source file instead of being a separate file of its own. How this works is explained in the next section.

Package options

Starting with version 3 the doc package now offers a small number of package options to modify its overall behavior. These are:

`hyperref`, `nohyperref` Boolean (default `true`). Load the `hyperref` package and make index references to code lines, pages, and other items clickable links. `nohyperref` is the complementary key.

`multicol`, `nomulticol` Boolean (default `true`). Load the `multicol` package for use in typesetting the index and the list of changes. `nomulticol` is the complementary key.

`debugshow` Boolean (default `false`). Provide various tracing information at the terminal and in the transcript file. In particular, this shows which elements are indexed.

`noindex` Boolean (default `false`). If set, all automatic indexing is suppressed. This option can also be used on individual elements.

`noprint` Boolean (default `false`). If set, then printing of element names in the margin is suppressed. This option can also be used on individual elements as described below.

`reportchANGEDates` Boolean (default `false`). If set, the changes in the change log are listed with headings of the form “*<version> – <date>*” instead of just displaying the version.

Instead of providing options to the `doc` package you can call `\SetupDoc{key/value list}` in the *<preamble>* and provide them there. This allows, for example, changing default values in case `doc` was already loaded earlier.

17.1.5 Conditional code in the source

The features discussed so far can be used to produce a L^AT_EX source in literate programming style that can be directly used by loading it as a package (where T_EX bypasses the comments) or printed by processing it with a driver file as explained in the previous section. This requires the structure of such a file to be linear; in other words, L^AT_EX sees *all* extracted code exactly in the order in which it is present in the file.

Experiences with the `doc` system soon suggested that it would be a valuable extension to be able to conditionally produce the ready-to-run files — by building them from several source files or extracting them from parts of one or more source files, for example. For this reason, the `doc` system was extended in two directions:

- A syntax was developed to label parts of the code so that the components could be referred to separately.
- The `DOCSTRIP` program (see Section 17.2), which was originally used only to strip the comments from `doc` files, was extended to offer a scripting language in which it became possible to specify how a ready-to-run file is generated from labeled code parts of one or more source files.

Of course, a source file containing such conditional code can usually no longer be used directly and requires the `DOCSTRIP` program before it can be turned into a ready-to-run file. However, the additional possibilities offered by this approach outweigh the inconvenience of an extra production step during installation so much that nearly all usages of `doc` now take advantage of it.

Code fragments for conditional inclusion are marked in the source file with “tags”. The simplest format is a `<*name>` and `</name>` pair surrounding some part of the code. This enables us to include or exclude that part by referring to its *name* in a DOCSTRIP script. The tags must be placed at the beginning of the line preceded by a `%`. For example:

```
%<*style>
    some lines of code
%</style>
```

It is possible to attach more than one tag to a part by combining several *names* with the Boolean operators `|` for logical “or”, `&` for logical “and”, and `!` for negation (using lazy evaluation from the left). For example,

```
%<*Aname|Bname&!Cname>
    some lines of code
%</Aname|Bname&!Cname>
```

means that this block should be included when either *Aname* is asked for or *Bname* is requested but *Cname* is not.

There are two other forms of directives for including or excluding single lines of code. A line starting with `%<+name>` or just `%<name>` is included (without its tag) if *name* is requested. A line starting with `%<-name>` is included if *name* is *not* requested in a DOCSTRIP run.

The above directives can be nested in each other. If this is done, the inner tags are evaluated only if the outer tags are true (i.e., if the whole block is requested for inclusion).

```
%<*Aname>
    code line 1
%<+Bname> code line 2
%<-Bname> code line 3
    code line 4
%</Aname>
```

Here nothing is included if *Aname* is not requested. If it is requested, we get code lines 1, 2, and 4 if *Bname* is also asked for, and lines 1, 3, and 4 otherwise.

You may have wondered how the conditional coding allows us to include the driver in the main source file. For this you have to place the code for the driver as the first code block and surround it by some tag (e.g., *driver*). If the user now runs the source file through L^AT_EX, the driver code is the first code that is not behind `%` signs, so it is executed. Because it ends in `\end{document}`, the L^AT_EX run will not execute any later code in the file. Thus, the documentation is typeset assuming that the driver loads the whole file using `\DocInput`. To generate the actual package file(s), you use a DOCSTRIP script (see Section 17.2 on page 599) that ignores the driver code by not requesting code from a block tagged *driver*.

17.1.6 Providing additional documentation elements

Out of the box the `doc` package offers the above commands and environments to document macros and environments. With version 3 this has now been extended in a generic fashion so that you can easily provide your own items, such as counters, length register, options, etc.

`\NewDocElement [key/value list] {name}{env}`

By convention the *name* has the first letter uppercased as in `Env` or `Macro`. Such a declaration will define for you a few commands and one environment:

- The command `\Describe{name}` with the same syntax as `\DescribeMacro` and `\DescribeEnv`.
- The environment `env`, which has the same syntax as `macro` or `environment`.
- The display command `\PrintDescribe{name}`, which has the same syntax as `\PrintDescribeMacro` or `\PrintDescribeEnv`.
- The `\Print{name}Name` display command that is used by the environment when displaying the element name in the margin, i.e., like `\PrintMacroName` or `\PrintEnvName`.

If any of the commands or the environment is already defined (which especially with a badly chosen *env* is a danger), then you receive an error telling you so.

If you want to modify an existing `doc` element, use `\RenewDocElement` instead. For example, the already provided “`Env`” `doc` element could have been defined simply by making the declaration `\NewDocElement{Env}{environment}` though that’s not quite what has been done, as we see later.

The optional *key/value list* defines further details on how that `doc` element should behave. The following keys are supported:

<code>macrolike</code>	Boolean (default <code>false</code>). Does this <code>doc</code> element start with a backslash?
<code>envlike</code>	Boolean. Complementary key to <code>macrolike</code> .
<code>toplevel</code>	Boolean (default <code>true</code>). Should a top-level index entry be made? If set to <code>false</code> , then either no index entries are produced or only grouped index entries are generated (see <code>idxgroup</code> for details).
<code>notoplevel</code>	Boolean. Complementary option to <code>toplevel</code> .
<code>idxtype</code>	String (default <code>env</code>). What to put (in parentheses if nonempty) at the end of a top-level index entry.
<code>printtype</code>	String (default <code>env</code>). What to put (in parentheses if nonempty) after an element name in the margin.
<code>idxgroup</code>	String (default <code>envs</code>). Name of the top-level index entry if entries are grouped. They are grouped only if this option is nonempty.

<code>noindex</code>	Boolean (default <code>false</code>). If set, this suppresses indexing for elements of this type. This setting overwrites any global setting of <code>noindex</code> .
<code>noprint</code>	Boolean (default <code>false</code>). If set, this suppresses printing the element name in the margin. This setting overwrites any global setting of <code>noprint</code> .

As usual, using a Boolean key without a value sets it to `true`.

In the syntax of `\NewDocElement` the two elements `Macro` and `Env`, provided by `doc` out of the box, are defined as follows:

```
\NewDocElement[macrolike, idxtype=, idxgroup=, printtype=]
    {Macro}{macro}
\NewDocElement[envlike, idxtype=env., idxgroup=environments,
    printtype=\textit{env.}] {Env}{environment}
```

This means that index entries for environments show the string “`env.`” after the name in the index, and they appear both on the top level as well as grouped under the heading “environments”. If typeset in the margin, they show “*env.*” after the environment name. If you prefer a different convention, use `\RenewDocElement` on these two elements.

For example, to set up a more structured index, all that you have to do is to define a few more doc elements and use them when documenting your code. For example, by using `notoplevel` and defining appropriate types to distinguish things like lengths, counters, public interface commands, etc., you can always group the commands by type, which might help your readers to find information easier.

```
\NewDocElement[macrolike, notoplevel, idxtype=, printtype=,
    idxgroup=Package interfaces] {Interface}{interface}
\NewDocElement[macrolike, notoplevel, idxtype=skip,
    idxgroup=LaTeX length\actualchar \LaTeX\ length (skip),
    printtype=\textit{skip}] {LaTeXSkip}{lskip}
\NewDocElement ...
```

Then use those doc elements instead or in addition to the commands and environments already offered by `doc` whenever appropriate. The package documentation of `doc` is an example of how this could look.

17.1.7 Producing the actual index entries

Several of the aforementioned macros produce one or more index entry. These entries have to be sorted by an external program — the current implementation assumes that the `MakeIndex` (or `upmendex`) program is used; see Chapter 14.

This is not built in: one has to redefine only some of the following commands to be able to use any other index program. All macros that are installation dependent are defined in such a way that they do not overwrite a previous definition. Therefore,

it is safe to put the changed versions in a package file that might be read in before the doc package.

To allow the user to change the specific characters recognized by the index program, all characters that have special meaning in the *MakeIndex* program are given symbolic names.

The `\actualchar` is used to separate the “sort key” from the actual index entry. The `\quotechar` has to be used before a special index program character to suppress its special meaning. The `\encapchar` separates the indexing information from a letter string, which *MakeIndex* turns into a T_EX command to format the page number associated with a special entry. It is used in this package to apply the `\main` and the `\usage` commands. Additionally, `\levelchar` is used to separate “item”, “subitem”, and “subsubitem” entries.

It is a good idea to stick to these symbolic names even if you know which index program is used. In this way your files remain portable. For example, you could make a manual index entry like this:

```
\newcommand\ltxconcept[1]{\index{LaTeX concepts\actualchar LaTeX\
                             concepts\levelchar #1\encapchar main}}
\ltxconcept{level character ‘\quotechar\levelchar’ in index}
```

With the default settings of doc this would produce the following line in the .idx file:

```
\indexentry{LaTeX concepts=LaTeX \ concepts>level character ‘!>’
              in index|main}{1}
```

i.e., the various commands got replaced by the appropriate characters. Note that this works only because we have used `\index` inside a command definition: if `\index` is used directly in the document, the argument is written fully verbatim, which is not what is wanted here.

The page or code line numbers for main index entries are encapsulated by the `\main` macro (underlining its argument), and the numbers denoting the description are encapsulated by the `\usage` macro (which by default produces *italics*). Finally, `\code` encapsulates page or code line numbers in entries generated by parsing the code inside macrocode environments. As usual these commands are user definable.

As an example we modify the index output to better indicate that some numbers mean line numbers by prefixing them with the letter *ℓ*:

```
\CodelineIndex
\renewcommand\code[1]{\mbox{$\ell$-#1}}
\renewcommand\main[1]{\underline{\mbox{$\ell$-#1}}}
```

17.1.8 Overview about all doc commands

We conclude this section with a few tables that briefly list all interfaces provided by the doc package, including some that we have not talked about before, e.g., parameters for altering the layout. If you need more information on any of them, take a look at the package documentation where all of them are discussed in further detail.

<code>\AlsoImplementation</code>	Typeset the complete file marked up according to doc conventions, including code part (default).
<code>\CheckModules</code>	Format module directives of DOCSTRIP specially (default).
<code>\CodelineIndex</code>	Index commands using code line numbers.
<code>\CodelineNumbered</code>	Number code lines but do not index commands.
<code>\DisableCrossrefs</code>	Do not produce index entries for commands within the code.
<code>\DocInput{file}</code>	Read in <i>file</i> assuming doc conventions.
<code>\DontCheckModules</code>	Do not format module directives of DOCSTRIP specially.
<code>\EnableCrossrefs</code>	Produce index entries for commands within the code.
<code>\IndexInput{file}</code>	Read in <i>file</i> , print it verbatim, and produce a command cross-reference index.
<code>\NewDocElement</code> <code>[key/values]{XX}{env}</code>	Declare a new doc element of type <i>XX</i> with the characteristics <i>key/values</i> using the environment <i>env</i> .
<code>\OnlyDescription</code>	Do not format code; stop at <code>\MaybeStop</code> .
<code>\PageIndex</code>	Index commands using page numbers.
<code>\PrintChanges</code>	Print the history listing here.
<code>\PrintIndex</code>	Print the index listing here.
<code>\RecordChanges</code>	Produce a history listing.
<code>\RenewDocElement</code> <code>[key/values]{XX}{env}</code>	Redeclare an existing doc element of type <i>XX</i> with the characteristics <i>key/values</i> using the environment <i>env</i> .

Table 17.1: doc — *Preamble and input commands*

<code>\bslash</code>	Print a backslash (<code>\</code>). Only useful in typewriter fonts!
<code>\cs{cmd}</code>	Print the argument as a command by using a typewriter font and prefixing it with a backslash.
<code>\DeleteShortVerb{c}</code>	Undo use of <code>\MakeShortVerb</code> or <code>\MakeShortVerb*</code> for character <i>c</i> .
<code>\DescribeEnv{env₁,...}</code>	Flag point in text where environment(s) <i>env₁</i> to <i>env_n</i> are described.
<code>\DescribeMacro{cmd₁,...}</code>	Flag point in text where the command(s) are described.
<code>\Describe{XX}{entry₁,...}</code>	Generalization of the above declared through <code>\NewDocElement</code> .
<code>\begin{environment}</code> <code>{env₁,...}</code>	Environment surrounding the definition of the environment(s) <i>env₁</i> to <i>env_n</i> .
<code>\Finale</code>	Command executed at very end of document (see also <code>\MaybeStop</code>).
<code>\begin{macro}{cmd₁,...}</code>	Environment surrounding the definition of the command(s) listed in the argument.
<code>\begin{macrocode}</code>	Environment surrounding the T _E X code.
<code>\begin{macrocode*}</code>	Same as the <code>macrocode</code> environment, but spaces are printed as <code>\code</code> characters.
<code>\MakeShortVerb{c}</code>	Define abbreviation character <i>c</i> for <code>\verb</code> .
<code>\MakeShortVerb*{c}</code>	Define abbreviation character <i>c</i> for <code>\verb*</code> .
<code>\MaybeStop{cmds}</code>	In the argument <i>cmds</i> , specify the commands that should be executed at the end of the document (they are stored in <code>\Finale</code>).
<code>\meta{arg}</code>	Print the argument as a meta sentence (default <code><arg></code>).
<code>\SpecialEscapechar{c}</code>	Specify new single escape character <i>c</i> to be used instead of the default backslash character to identify the start of a command in code of the next <code>macrocode</code> or <code>macrocode*</code> environment.
<code>\begin{verbatim}</code>	Slightly altered version of L ^A T _E X's standard <code>verbatim</code> environment to surround verbatim text ignoring percent characters in column 1.
<code>\begin{verbatim*}</code>	Same as the <code>verbatim</code> environment, but spaces are printed as <code>\code</code> characters.

Table 17.2: doc — Document structure commands

<code>*</code>	Symbol used in index entries to refer to a higher-level entry (default ~).
<code>\actualchar</code>	Character used to separate “key” and actual index in an index entry (default =).
<code>\DoNotIndex{cmd₁,...}</code>	Names of commands that should not show up in the index. This can be used several times.
<code>\code{number}</code>	The formatting style for code line or page numbers of index entries generated while parsing the code lines in <code>macrocode</code> environments. By default the <i>number</i> is used unchanged without special formatting.
<code>\encapchar</code>	Character used to separate the actual index and the command to format the page number in an index entry (default).
<code>\IndexMin</code>	Length parameter (default 80pt) defining the minimal amount of space that should be left on a page to start an index.
<code>\IndexParms</code>	Macro controlling the formatting of the index columns.
<code>\IndexPrologue{text}</code>	Specify (overwrite) the text placed on top of the index.
<code>\levelchar</code>	Character used to separate different index levels in an index entry (default >).
<code>\main{number}</code>	The formatting style for page numbers or code line numbers of index entries for major references (default underlined digits).
<code>\quotechar</code>	Character used to suppress the special meaning of the following character in an index entry (default !).
<code>\SortIndex{key}{entry}</code>	Produce an index entry for <i>entry</i> , sorting it by <i>key</i> .
<code>\Special<XX>Index{entry}</code>	Produce a usage index entry for <i>entry</i> , which is a doc element of type <XX> (i.e., Macro or Env by default or one defined by <code>\NewDocElement</code>) using a <code>\usage</code> page encapsulator.
<code>\SpecialMain<XX>Index{entry}</code>	Produce a main index entry for <i>entry</i> , which is a doc element of type <XX> (<code>\main</code> page encapsulator).
<code>\SpecialIndex{cmd}</code>	Produce a command index (printing the argument verbatim in the index). If the command is of a special type for which there is a doc element declared, it is automatically recognized.
<code>\SpecialShortIndex{c}</code>	Produce a command index for a single character command <code>\c</code> . Some of them do not sort correctly if <code>\SpecialIndex</code> would be used, e.g., <code>\{</code> ; therefore, doc uses a special (slow) command for them.
<code>\usage{number}</code>	The formatting style for page numbers of index entries for usage descriptions (default italic digits).
<code>\verbatimchar</code>	Character used to delimit <code>\verb</code> constructs within an index entry (default +).

Table 17.3: doc — Index commands

<code>\changes{version}{date}{reason}</code>	Record <i>reason</i> for <i>version</i> written on <i>date</i> as history information for use in a history listing. Use YYYY/MM/DD or YYYY-MM-DD for <i>date</i> .
<code>\GlossaryMin</code>	Length parameter (default 80pt) defining the minimal amount of space that should be left on a page to start the change history.
<code>\GlossaryParms</code>	Macro controlling the formatting of the change history columns.
<code>\GlossaryPrologue{text}</code>	Replace (overwrite) the default text placed on top of the history listing.

Table 17.4: doc — History information

<code>\@idxitem</code>	Macro specifying how index items should be typeset (by default, they are set as a paragraph with a hanging indentation of 30pt for items requiring more than one line).
<code>\AltMacroFont</code>	Font used to typeset DOCSTRIP module code (default <code>\small\ttfamily\slshape</code>).
<code>\DocstyleParms</code>	Macro controlling the formatting of the T _E X code.
<code>\generalname</code>	String placed before change entries on the top level.
<code>\MacrocodeTopsep</code>	Vertical space above and below each macrocode environment.
<code>\MacroFont</code>	Font used to typeset the main part of the code (default <code>\small\ttfamily</code>).
<code>\MacroIndent</code>	Width of the indentation for every code line.
<code>\MacroTopsep</code>	Vertical space above and below each macro environment.
<code>\MakePercentComment</code>	Activate “%” as T _E X’s comment initiator character.
<code>\MakePercentIgnore</code>	Deactivate “%” as T _E X’s comment initiator character.
<code>\MakePrivateLetters</code>	Macro specifying symbols to be considered as letters (default @).
<code>\Module</code>	Macro with one argument defining the formatting of DOCSTRIP module directives.
<code>\PrintDescribe<XX>{entry}</code>	Command with one argument defining the formatting of <code>\Describe<XX></code> .
<code>\Print<XX>Name{entry}</code>	Like <code>\PrintDescribe<XX></code> but for the argument of the environment surrounding the definition.
<code>StandardModuleDepth</code>	Counter holding the highest level of DOCSTRIP directives, which are still formatted using <code>\MacroFont</code> . Deeper-nested directives are formatted using <code>\AltMacroFont</code> .
<code>\theCodelineNo</code>	Control the typesetting of line numbers (default script-size arabic numerals).

Table 17.5: doc — Layout and typesetting parameters

17.1.9 ltxdoc — A simple L^AT_EX documentation class

The `ltxdoc` class was designed for documenting the core L^AT_EX source files, which are used to build the L^AT_EX format and all packages distributed as part of the core distribution. This class is built on the `article` class, loads the `doc` package, but extends it slightly with a few commands that we found helpful for documenting L^AT_EX kernel code. It also includes some layout settings specially tailored to accommodate the typical requirements of a source file in `doc` style (e.g., a line width to hold 72 characters in typewriter fonts and a wider left margin to allow for long macro names to be placed into it).¹

A special feature is that the class can be used to produce a single document from a larger number of source files in `doc` style. This has the advantage that one can produce a full index of macro usage across all source files. For example, the driver file `source2e.tex` generates the documented source listing of the close to 60 files that make up the L^AT_EX kernel. It generates a document with more than 1200 pages including an index and a change history (reaching back to the early 1990s).

¹These days we often use `l3doc` for L^AT_EX Project documentation. However, this class is far from being finalized, and there are plans to alter it drastically — we therefore do not recommend using it, unless you are prepared to update your sources when it changes!

Extensions provided by ltxdoc

As extensions, the class offers a small set of commands to describe L^AT_EX commands and their arguments. These commands really should have been in the doc package, but due to some historical accident have never been added there.

```
\cmd{\name} |...| \marg{arg} \oarg{arg} \parg{arg}
```

The command `\cmd` prints a command *name* in typewriter font; for example, writing `\cmd{\foo}` typesets `\foo`. In contrast to `\verb+\foo+` (which is otherwise similar), it can be used anywhere — even in the arguments of other commands. The command `\cs`, which is already part of the doc package, offers the same functionality for those who prefer the syntax without the backslash. In fact, it is slightly more powerful because it can also typeset commands that are made `\outer` — a plain T_EX concept normally not used in L^AT_EX. Furthermore, ltxdoc makes “|” an abbreviation for `\verb` so that you can type `|\foo|` in the documentation. If this is not desired for some reason, you have to cancel it in the source (after `\begin{document}`) via `\DeleteShortVerb{|}`.

The commands `\marg`, `\oarg`, and `\parg` produce the L^AT_EX syntax for mandatory, optional, and picture arguments, respectively. Thus, writing

```
\cs{makebox}\parg{x-dimen,y-dimen}\oarg{pos}\marg{text}
```

produces the (probably less-known) syntax diagram for `\makebox` in picture environments: `\makebox(<x-dimen,y-dimen>)[<pos>]{<text>}`.

```
\DocInclude{file}
```

The `\DocInclude` command is similar to `\include` except that it uses `\DocInput` on *file* (with the implicit extension `.dtx` or `.fdd`) instead of using `\input` on a *file* (with the implicit extension `.tex`). This command is used in `source2e.tex` to “include” all `.dtx` files that form the L^AT_EX kernel.

Customizing the output of documents that use ltxdoc

To customize documents using the ltxdoc class you can create a configuration file (`ltxdoc.cfg`). This configuration file is read whenever the ltxdoc class is used, so it can be used to customize the typesetting of all the source files, without having to edit lots of small driver files, which would be the manual alternative.

If `ltxdoc.cfg` is installed in a directory always searched by L^AT_EX, it is applied to all documentation files using the ltxdoc class. If it is placed in the current directory, it applies only to documents processed in this directory.

The simplest form of customization is to pass one or more options to the article class upon which ltxdoc is based. For instance, if you wish all your documentation to be formatted for A4 paper, add the line

```
\PassOptionsToClass{a4paper}{article}
```

to `ltxdoc.cfg` and install it in a place searched by L^AT_EX.

As discussed in Section 17.1.2, the `\MaybeStop` command separates the source files into a “user” documentation and an “implementation” part. To be able to produce only the user manual, the `doc` package provides the command `\OnlyDescription`, which suppresses the implementation part. This command may also be used in the configuration file, but as the `doc` package is loaded after the configuration file is read, you must delay the execution of `\OnlyDescription`. The simplest way is to use `\AtBeginDocument` as follows:

```
\AtBeginDocument{\OnlyDescription}
```

For example, the documented source of the `array` package, the file `array.dtx`, generates 35 pages of documented code listings if you run

```
pdflatex array.dtx
```

without a configuration file. However, most people are not interested in *how* commands are implemented in this package, but rather what interfaces the package provides and how to use them. With the above configuration line the output is reduced to an 8-page user manual, listing only the interfaces together with a few examples.

When the driver `source2e.tex` for the kernel documentation is processed, an index and a change history are produced by default; however, indexes are not normally produced for individual files. If you are really interested in the source listings in detail, you probably want to have an index as well. Again, the index commands provided by the `doc` package may be used, and again their execution must be delayed. Thus, the addition to the configuration file could look as follows:

```
\AtBeginDocument{\AlsoImplementation % force processing everything
                  \CodelineIndex      % select index per code line
                  \EnableCrossrefs }  % enable it
\AtEndDocument{\PrintIndex}
```

Similar lines would be necessary if you want to produce a change history listing. Recall that the `doc` package generates `.idx` and `.glo` files with a special syntax that requires adequate style files for processing with *MakeIndex* (see Section 17.1.3 on page 588).

17.2 docstrip.tex — Producing ready-to-run code

When `doc` was originally written in the late 1980s, the intention was to provide a “literate programming” environment [83] for \LaTeX , in which \LaTeX code and documentation were intermixed in the same source file. As it soon turned out, making \TeX parse (and then ignore) all the documentation when reading a file added a heavy time penalty.¹ To avoid this problem the author looked for ways to automatically strip all comments from files written for the `doc` system.

¹In those days producing a single page with \TeX could easily take half a minute or longer.

The problem with any external program developed for such a purpose is that it may or may not be available for the user's operating system and even if available may not be installed. But one program is always available on a system that can run L^AT_EX: the T_EX program itself. To achieve the widest portability, the DOCSTRIP program was therefore written in low-level T_EX language. Since those early days, the program has undergone many revisions that changed its purpose from being a simple stripping device to serving as a fully customizable installation tool — one that is even able to distribute files to the right directories on a target machine. Johannes Braams, Denys Duchier, Marcin Woliński, Mark Wooding, David Carlisle, and others contributed to this metamorphosis; details of the program's evolution can be found in the documented source (which uses literate programming, of course). Here are today's main applications of the DOCSTRIP program:

- Strip a literate programming source of most of its documentation (i.e., the lines that start with a single % sign in the first column).
- Build ready-to-run code files by using code from one or more source files and including parts of it according to options specified.

It is also possible with DOCSTRIP to automatically install the produced files in the right directories on the target machine if desired, which was initially important for a smooth update process. However, today this is better handled through l3build (see Section 17.3), so this is not covered in the book.

Will Robertson has produced a nice gallery [170] of sample .dtx files that exhibit various techniques using DOCSTRIP. Take a look at this after having read the current section.

17.2.1 Invocation of the docstrip utility

From its first days of existence DOCSTRIP could be run interactively by processing `docstrip.tex` with L^AT_EX:

```
latex docstrip.tex
```

L^AT_EX then asks a few questions about how to process a given file. When the user has answered these questions, DOCSTRIP does its job and strips the comments from the source.

However, this method of processing was intended to do nothing more than stripping off comments. With today's sources, which contain conditional code and are intended to be combined to form the final “executable”, it is usually no longer appropriate. Instead, the developers of packages typically provide an installation file (by convention having the extension `.ins`) that is used to invoke DOCSTRIP behind the scenes. In this case the user simply says

```
latex <name>.ins
```

This results in the generation of all “executables” from the source distribution and

optionally installs them in the right places. All standard \LaTeX distributions (e.g., base, graphics, and tools) are distributed in this form and so are most contributed packages that are described in this book. In the next section we discuss how to construct your own installation scripts for DOCSTRIP.

17.2.2 docstrip script commands

A DOCSTRIP installation script has the following general form:

```
\input docstrip
<other DOCSTRIP commands>
\endbatchfile
```

It starts by loading the DOCSTRIP code using the \TeX primitive `\input` (typically without braces¹ around the file name).

This is followed by the DOCSTRIP commands that actually do the work of building new files, communicating with the user, and carrying out other necessary tasks. At the very end, the script contains `\endbatchfile`. Without that statement, DOCSTRIP would display a `*` prompt while waiting for further input from the user.

Generating new files

The main reason for constructing a DOCSTRIP script is to describe which files should be generated, from which sources, and which optional (tagged) chunks of code should be included. This is done by using `\generate` declarations.

```
\generate{\file{result-file1}{\from{source-file1}{tag-list1}
                                     \from{source-file2}{tag-list2}
                                     ...
                                     \from{source-filen}{tag-listn}}
      ...
      \file{result-filen}{...}
}
```

Within the argument to `\generate` you specify the *result-files* you want to produce by using `\file` declarations. The second argument to `\file` contains one or more `\from` commands listing the *source-files* that should be used to build one *result-file*. With each `\from` declaration the second argument specifies the *tag-list* to use with the particular *source-file*. Then only the code chunks tagged with the appropriate tags and all the untagged source lines from that file are included (see Section 17.1.5 on page 590 for a description how to tag code).

The *source-files* are used in the order specified: first the code from *source-file₁* is included (according to the tag specification), then the code from *source-file₂*, and so on. The *tag-lists* in each `\from` command are comma-separated lists and indicate that code with these tags should be included.

¹ This is actually no longer necessary because nowadays `\input` always accepts a braced argument.

With the syntax specification for `\generate` as given above, you can produce a single *result-file* from one or more *source-files* by using a single `\file` declaration. By repeating this as often as needed, any kind of distribution can be produced. It is, however, not very efficient. Suppose you have one large source file from which you want to produce many small files—for example, suppose the source for the doc package, `doc.dtx`, is used to generate `doc.sty`, `shortvrb.sty`, `gind.ist`, and `gglo.ist`. The file is nearly 5000 lines long, so by using four `\generate` declarations, DOCSTRIP would have to process 20000 lines. To speed up this process, `\generate` allows you to specify several `\file` commands within its argument. These files are processed in parallel, meaning that the *source-files* are opened only once, and distribution of source code to *result-files* is done in parallel.

```
\generate{\file{doc.sty}{\from{doc.dtx}{package}}
          \file{shortvrb.sty}{\from{doc.dtx}{shortvrb}}
          \usepostamble\istpost
          \file{gind.ist}{\from{doc.dtx}{gind}}
          \file{gglo.ist}{\from{doc.dtx}{gglo}}}
```

As you can see, certain other commands (`\usepostamble`, for example) are allowed within the argument of the `\generate` command. In the above example this has the effect of replacing the standard postamble with a different one (because the standard postamble adds an `\endinput` to the end of the generated file, something not desirable in a style file for *MakeIndex*).

*Restrictions on
parallel extraction*

There are some restrictions with this approach. For instance, DOCSTRIP complains if the order of source files in one `\file` command conflicts with the order in a different one; the precise rules are discussed in the DOCSTRIP documentation [142]. If that happens, the simplest solution is to use two separate `\generate` declarations.

Communicating with the user

The DOCSTRIP scripting language offers some limited possibilities for user communication. Keep in mind that interactive questions, though sometimes useful, can make an installation process quite cumbersome, so these tools should be used with care.

```
\Msg{message}      \Ask{cmd}{question}
```

The `\Msg` command can be used to present a *message* on the terminal; thus, it offers a similar functionality as L^AT_EX's `\typeout` command. `\Ask` is similar to L^AT_EX's `\typein` command, with the difference that no trailing space is generated from pressing return in reply to a *question*. This way simple questions can be asked (using a bit of low-level programming). For example:

```
\Ask\answer{Should we continue? (y/n)}
\ifx\answer\y
  % code for ‘y’ as answer
\else
  % otherwise
\fi
```

```
\ifToplevel{code}
```

You may want to give certain information, or run certain code, only if a DOCSTRIP script is executed on its own, but not if it is called as part of a larger installation (see below). Such information or code can be placed in the argument of an `\ifToplevel` command. For example, all the individual installation scripts from the \LaTeX base distribution say what to do with the generated files. However, if you use the main installation script `unpack.ins`, the messages in the subscripts are suppressed to avoid repeating the same information over and over again.

```
\askforoverwrite true   \askforoverwrite false
```

Before DOCSTRIP writes its output to a file, it checks whether that operation would overwrite some existing version of this file. If so, the default behavior is to ask the user if overwriting is acceptable. This check can explicitly be turned off (or on if it was turned off) by using the command `\askforoverwrite false` or `\askforoverwrite true`, respectively, in the DOCSTRIP script.

```
\askonceonly
```

Setting `\askforoverwrite false` in a distribution script may not be the right thing to do, because it essentially means that it is okay to overwrite other people's files, no matter what. However, for large installations, such as the base \LaTeX distribution, being asked individually about hundreds of files is not very helpful either. For this reason DOCSTRIP offers the declaration `\askonceonly`. This means that after the first time the script asks the user a question, the user is given an option to have DOCSTRIP assume that all future questions will get a “yes” as the answer. This applies to *all* future questions (manually produced by `\Ask` or generated through a file overwrite).

```
\showprogress   \keepsilent
```

For amusement and because in the original implementation everything was so slow, there was a way to direct DOCSTRIP to show its progress when stripping comments and building new files. These days most scripts run in silent mode.

Top-level/main installation scripts

In large distributions, such as the \LaTeX base distribution, it is convenient to provide separate DOCSTRIP scripts for processing individual parts. For example, `format.ins` generates the main format file `latex.ltx` and its customization files such as `fonttext.cfg`, and `classes.ins` generates the standard classes, such as the files `article.cls` and `report.cls`.

Nevertheless, you do not want to force the user to process a dozen or more installation scripts (30 in the case of the \LaTeX base distribution). Therefore, DOCSTRIP offers the command `\batchinput`, which enables you to include installation scripts in some top-level installation script. Do not use `\input` for this purpose, because this

command is exclusively reserved for loading the DOCSTRIP code once, as explained above, and is ignored otherwise. Except for the fact that it contains some special handcrafted code at the beginning so that it can be processed using `initex`, the file `unpack.ins` from the base L^AT_EX distribution is a good example for such a main installation script.

Setting up preambles and postambles

As mentioned earlier, DOCSTRIP not only writes selected lines of code to the output files but also precedes them with a *preamble* and finishes each file with a *postamble*. There are default texts for both operations, but usually a DOCSTRIP script explicitly defines what should be used in these places, such as a copyright notice or your standard disclaimer (see also [109]).

<pre>\preamble <text lines> \endpreamble \postamble <text lines> \endpostamble</pre>

The information that you want to add to the start of DOCSTRIP's output file should be listed between the `\preamble` and `\endpreamble` commands. Lines that you want to add at the end should be listed between the `\postamble` and `\endpostamble` commands. Everything that DOCSTRIP finds for both the preamble and postamble is written to the output file, but preceded with two % characters (or, more exactly, with the current definition of the command `\MetaPrefix`). In general, only straight text should be used, and literal command names should be of the form `\string\foo`. In addition to the user preamble, DOCSTRIP also includes some information about the current file (i.e., its name and the sources from which it was generated). This information is always added unless you use `\nopreamble` (see below) or you sidestep the standard preamble generation (explained in the DOCSTRIP package documentation [142]).

It is also possible to define a number of “named” preambles or postambles and later refer to them when generating files. In fact, this is the usual way to produce the preambles in larger projects.

<pre>\declarepreamble\cmd <text> \endpreamble \usepreamble\cmd \declarepostamble\cmd <text> \endpostamble \usepostamble\cmd</pre>

The `\declarepreamble` declaration works like `\preamble` except that it stores the preamble text for later use in `\cmd`. To activate such a preamble, `\usepreamble` is called in a DOCSTRIP script. For postambles, the declarations `\declarepostamble` and `\usepostamble` are provided. Examples of them can be found in all DOCSTRIP installation scripts in the distributions of the standard L^AT_EX components.

<pre>\nopreamble \nopostamble</pre>
--

To fully suppress the writing of a preamble or a postamble, you can use the declarations `\nopreamble` and `\nopostamble`, respectively.

17.2.3 Using docstrip with L3 programming layer code

The L3 programming layer has a few special conventions. For example, it has the concept of private commands indicated by starting a command name with two underscores, e.g., `__para_handle_indent:.` Such commands are not supposed to be used outside of the package or the \LaTeX kernel. The same concept exists for variables, except that they start with `\l__` or `\g__`, for example, `\g__para_std_everypar_tl`. To ease code development and maintenance you can put a `doc` directive into your source, such as

```
%<@@=para>
```

after which you can write `\@@_handle_indent:` or `\g_@@_std_everypar_tl`. The `@@` is then automatically replaced with the right numbers of underscores and the module name (in this case `para`), when the source is stripped with `DOCSTRIP`. The same happens if you generate the source code documentation using the `l3doc` class, but if the source is processed with the standard `doc`, the `@@` are left unchanged in the source, because `doc` was developed for $\text{\LaTeX} 2_{\epsilon}$ code that uses `@` in other ways.

You end the private module handling with the line `%<@@=>`. If your code uses commands that have two consecutive `@` signs in their name, e.g., `\@@par`, you need to enter such names using `@@@` while private module handling is in force.

17.2.4 Using docstrip with other languages

With some restrictions it is possible to use the `DOCSTRIP` mechanism to distribute and generate files not intended for a \TeX installation. What you have to bear in mind is that `DOCSTRIP` operates on a line-by-line basis when reading source files. As a result, doing something like unpacking binary files with it is bound to produce unusable files.

Furthermore, the use of preambles and postambles is likely to conflict with the syntax requirements of the language for which the file is intended. For example, generating a shell script with a number of lines starting with `%%` is probably not a good idea. This problem can be circumvented by changing the `\MetaPrefix` (which by default produces `\DoubleperCent`). For a shell script, where you probably want a `#` sign as the comment character, this modification can be a little tricky, because \TeX regards the `#` as special. Use

```
\renewcommand\MetaPrefix{\string##}
```

to produce a single hash sign as a `\MetaPrefix`. To return to the default setting, use the following definition:

```
\renewcommand\MetaPrefix{\DoubleperCent}
```

Another potential problem to watch out for is `DOCSTRIP`'s standard behavior of stripping away all lines starting with a single percent sign. If your code contains such

*Changing the
comment character*

Verbatim copying

lines, you may want to retain them. This can be achieved by surrounding that block with two special lines as follows:

```
%<<tag-name
  <code lines to be copied verbatim>
%tag-name
```

You can use any *tag-name*. The important point is that this “verbatim” block ends when DOCSTRIP encounters a single line just containing a percent sign followed by *tag-name*. The other important point to note is that the *tag-name* is not used for conditional exclusion or inclusion but only for specifying the block to be copied verbatim. If such a block should be written only in some circumstances, as controlled through the second argument of `\from`, you have to additionally surround it by a set of conditional tags (see Section 17.1.5).

17.3 l3build — A versatile development environment

Making a package available to the L^AT_EX user community requires several steps: we call those *releasing* the package. Most obviously, almost all packages have PDF (Portable Document Format) documentation that needs to be compiled, including, for example, creating an index of commands. This will often be coupled with extracting code using DOCSTRIP, and to send to CTAN, creating a `.zip` file (see below). It is of course possible to do all of this by hand, but that tends to be error prone. To make this entire process more fluid, the L^AT_EX Project Team has developed l3build as a flexible tool to support development work.

The l3build program is a Lua script designed to support a range of workflows using a set of simple settings as far as possible. As such, it is quite usable without being familiar with Lua.¹

l3build can carry out unpacking, typesetting, packaging, and uploading for release. It also features a sophisticated ability to carry out tests to probe the functionality of L^AT_EX code: this is an important concept and is covered in more detail in Section 17.3.2.

Because l3build is used to release all of the code authored by the L^AT_EX Project Team, including L^AT_EX itself, it has some advanced options for handling bundles of packages, nonstandard file locations, etc. In this book, the focus is on the more common situation of a single package made up of a small number of source files in one directory. This covers the needs of most package authors, but if you have more complex requirements, they are most likely covered by the more than 100 keys that can be set or altered in a configuration file; for this, take a look at the documentation [147].

l3build uses a dedicated directory (by default called `build`) that it creates inside the main directory holding your sources. This means that it can reliably copy *just* the files you specify into its working area, and that if you need to, you can delete all

¹l3build uses Lua because this is an integral part of LuaT_EX and therefore available on any system that has a modern T_EX system. This means that Lua is widely used in the T_EX ecosystem for scripting.

of the temporary material created in one go. This is also useful if you use a version control system for your package development (see Section 17.4 on page 615): there is just one location to tell it to ignore.

17.3.1 The basic interface

l3build is available in modern T_EX systems as a script that can be run directly at the command line/terminal. The script understands a range of *targets*, for example `doc` (for typesetting package documentation). Some targets take further arguments specifying one or more names to process. There are also a number of options, with which you can tune the target behavior. For example, to run two tests, called `mypkg001` and `mypkg002`, using the pdfT_EX engine, the appropriate call is

```
l3build check --engine pdftex mypkg001 mypkg002
```

or shorter

```
l3build check -e pdftex mypkg001 mypkg002
```

All of the switches have a “long” name: some also have a “short” one for convenience.

Control of l3build is achieved by creating a file called `build.lua` in the main development directory for a package. In most cases, this will be the directory containing all your package sources, but complicated projects may structure the source files differently. Taking the very common case of a single `.dtx` file with a matching `.ins` file, all that is necessary is to inform l3build of the name to use.¹ The minimal contents of the `build.lua` file for a package `mypkg` would therefore be

Setting up a simple package

```
-- Build script for "mypkg" files

module = "mypkg"      -- Identify the package
```

Because the control file is written in Lua, line comments start with `--`, not `%`.

The standard settings in l3build specify that all of the `.dtx` files in the directory are taken as source files and that each `.ins` file is passed to DOCSTRIP for unpacking. Thus, with this minimal setup, you can already use various l3build commands.

l3build install Unpacks the code and installs it into the local T_EX tree, typically `~/texmf` on Linux, `~/Library/texmf` on macOS, or `%USERPROFILE/texmf` on Windows.

l3build uninstall Removes any code installed in the location that would be used by `l3build install`.

l3build check Runs all of the tests you have created for the package: this process is described in more detail in Section 17.3.2. Individual tests can be run as we have already seen by adding their names after the `check` target keyword.

¹l3build uses the name `module`: this aligns with the way that for example Lua refers to loadable files providing additional functionality.

l3build doc Typesets the documentation, which will be carried out by running a cycle of pdfT_EX and *MakeIndex* runs for each file marked as a documentation target (by default all .dtx files, but see page 614). If you want to compile a single PDF, you can give its name (without the extension) after the doc target keyword.

l3build install --full Combines l3build doc with l3build install, meaning that the PDF documentation is installed along with the code.

l3build ctan Runs any tests available (see Section 17.3.2), then runs l3build doc, and finally builds a .zip file containing the PDFs, the .dtx and .ins files, and any .md or .txt file, suitable for upload to CTAN (see Section 17.3.3 on page 611). If any of the steps fail, the target stops: in particular, this prevents a release if there are any failing tests.

17.3.2 Creating tests

For larger projects, most notably the L^AT_EX kernel, a comprehensive test suite is essential in reducing the likelihood of problems for users. However, even for smaller packages tests are useful in helping to spot problematic changes, and we therefore encourage everyone to use them for every project. Testing is an integral part of l3build and can be carried out in a number of ways.¹

How tests work

Testing using l3build works using the .log file²: T_EX can be asked to write a wide range of information to file. However, T_EX also writes a large amount of other material, for example, file paths, details of the engine, the output of third-part packages, etc. The approach used by l3build is therefore to manipulate the raw .log file to produce a normalized file, which should be identical between different computers and which avoids as far as possible differences between T_EX engines (pdfT_EX, X_YT_EX, LuaT_EX, etc.). For example, dates and version numbers or low-level register numbers are masked out and spaces are normalized to avoid unnecessary failures between runs and between different engines that are unfortunately writing to the .log in slightly different ways.

For this process to produce *useful* tests, it is important that the author writes the useful information to the .log. Using `\tracingall` produces a lot of output but is almost always the wrong choice. The trace will always show differences whenever a code change is made, but that does not reflect at all whether the *results* are changed. For example, reworking an internal macro to be more efficient will normally not change the result, but alters the trace. Instead, you should be selective in what you write, for example the typeset result of a specific command, or the numerical value of a calculation, etc.

¹The core of l3build is based on previous more focused test systems used by the L^AT_EX Project Team: l3build not only makes this functionality into a documented product but also provides the wider building environment that allows almost full automation.

²Testing using other files is possible, most notably using a specially modified PDF file to assess final output. However, this is a much more specialized approach, so the focus here is on the standard method.

A good practice is to write a test file for every bug report you receive and have fixed to ensure that the problem does not reappear through later modifications.¹

Test setup

To create a set of tests for use with l3build, a directory called `testfiles` should be created inside the main directory. Inside the `testfiles` directory, one or more test sources are required: these have the extension `.lvt`. These are specially crafted \LaTeX files that load the file `regression-test.tex`, which provides a small number of testing commands: these all have all-caps names.

To allow loading packages, etc., without this affecting the tests, l3build ignores anything before the command `\START`. You can also skip material using an `\OMIT ... \TIMO` block. The tests (and indeed the \LaTeX run) can be ended using `\END` or the standard `\end{document}` command: the `\END` command attempts to stop immediately and does not produce the last page of output (which is fine if you are interested only in the content of the `.log`). Because it reduces the work \TeX does, `\END` is faster than `\end{document}`. It should be preferred where possible, especially if you expect to have a large suite of tests to be executed regularly.

Constructing tests

There are two main ways to write information to the `.log` so that the results can be checked by l3build. The first is to actively write results using the command `\TYPE` (this is a specially modified version of `\typeout`). To make it easier to follow the results, tests are normally divided up into one or more `\TEST` blocks. Thus, a simple test file might read

```
\input{regression-test}
\documentclass{article}
\usepackage{mypkg} % The package to test
\START
\TEST{A first test}{%
  \mypkfunctionA{input-tokens}\outputmacro
  \TYPE{\outputmacro}
}
\TEST{A second test}{%
  \mypkfunctionB{input-tokens}{more-input-tokens}\outputmacro
  \TYPE{\outputmacro}
}
\END
```

This approach is particularly useful for code, which produces values that are stored in commands, counters, etc.: they can be written to the `.log` directly. Usefully, the `\TEST` command places the test code argument in a group: this means that local changes do not affect subsequent tests.

¹It is surprising how many “harmless” changes that “surely can do no harm” have triggered test failures and in this way have saved the \LaTeX Project Team from releasing faulty code.

The second approach, useful for typesetting commands, is to use T_EX’s ability to record the contents of a box or of the whole output page. The latter is particularly convenient, because it can simply be switched on with `\showoutput`, and multiple tests then appear in the output.

```
\input{regression-test}
\documentclass{article}
\usepackage{mypkg}           % The package to test
\showoutput                  % show symbolic page output in the .log
\begin{document}
\START
\mypkfunctionA{input-tokens} % Assume this produces typeset output

\mypkfunctionB{input-tokens}{more-input-tokens}
\newpage
\OMIT
\end{document}
```

As illustrated, this type of test needs `\end{document}` to be present in the source, and it is usually best to force a new page and then tell l3build to ignore the remainder of the `.log` using `\OMIT`. Given that the output here is given by T_EX in one block, it is usually not beneficial to use the `\TEST` command.

Unfortunately, the result from `\showoutput` can differ in different engines. While pdfT_EX and X_YT_EX usually (but not always) show the same symbolic output, LuaT_EX often has subtle differences, e.g., a space between the command `\kern` and its value in some places but not in others. If you test with different engines,¹ this means that you may have to store engine-specific results and verify them individually, as explained below.

The machinery for this is available, but the danger is that one overlooks a real bug among the “expected” differences and certifies an incorrect result as the expected output — it happened to us more than once, so be careful.

Certifying and saving tests

To save a test, the l3build command is simple:

```
l3build save <test file without extension>
```

This creates a single `.tlg` file containing the normalized results: as far as possible, system- and engine-dependent information is removed from the raw `.log`.

l3build itself of course does not have any insight into whether a `.tlg` file is showing the *correct* results, only that it is what has been produced from a L^AT_EX run. You should therefore check new `.tlg` files, along perhaps with the typeset output, when you create them. Once saved, the automated system is then able to highlight

¹The regression test suite with about 1000 tests is executed with pdfT_EX, X_YT_EX, and LuaT_EX and needs nearly 20 minutes to verify that everything is fine before we upload a new release.

changes, which may of course be deliberate because you altered the code: only the package author can check that! If a test shows differences and you verified them as being correct, you need to regenerate the `.tlg` file to get a new certified reference result — otherwise you must check what is wrong with the package.

With the standard settings, l3build runs each test using pdfTeX, XeTeX, and LuaTeX. You may need to save separate engine-specific `.tlg` files, particularly if you are testing using the typeset output. This is achieved using the `-e` or `--engine` switch, which takes a comma-separated list of engine names.

```
l3build save -e xetex,luatex <test file without extension>
```

When an engine-specific `.tlg` file is available, this is used by l3build in preference to the engine-independent reference file. You can adjust the engines that are used by setting the `checkengines` table, for example to use just pdfTeX and LuaTeX add the following to `build.lua`:

```
checkengines = {"pdftex", "luatex"}
```

The first entry is used as the *standard engine*: the one that is used if you do not give the `-e` option to the `save` target.

Testing package loading

One area that is usually best covered by a stand-alone test file is package loading. This is a good way to pick up any errors within the code that show up only when the package is first read by L^AT_EX. A simple test such as the one below does that:

```
\input{regression-test}  
\documentclass{article}  
\START \usepackage{mypkg} \END
```

If your package takes options, you may want several such tests with different combinations of them. The reason why these are best handled separately from other tests is that package loading is more likely to show spurious differences in the `.tlg` files, because your package might load other packages that output irrelevant data, which you cannot suppress.

For the same reason it is normally best to use `\START` only after the preamble has ended or, if that is not possible because you want tests in the preamble, to surround `\begin{document}` with `\OMIT` and `\TIMO`.

17.3.3 Releasing to CTAN

CTAN, the Comprehensive T_EX Archive Network, is the major distribution center for L^AT_EX packages. This means that releasing a L^AT_EX package to the wider L^AT_EX community actually means submitting it to CTAN; see Appendix C.4.1 on page 789.

CTAN holds a range of both L^AT_EX packages and support tools. The archive is not prescriptive about, for example, overlap of package functions or the way material

is coded: anyone who feels that their code should be available on CTAN can upload. However, the CTAN team members ask for certain conditions to be met by the files uploaded, in particular

- that there is at least one PDF file containing documentation;
- that there is a README (plain text) or README.md (Markdown) file;
- that *derived* files (other than PDF documentation) are not uploaded: this means if a package uses a .dtx, the .sty, or other generated files, are not sent to CTAN;
- and that the uploaded files are present in a single archive: .zip or .tar.gz.

The `l3build ctan` target automatically arranges that the appropriate files are present in a .zip file that can be uploaded. This can be used with the web submission form (<https://ctan.org/upload>). Optionally, `l3build` can send the zip file directly to CTAN, avoiding the need to visit the website. To do this, `l3build` needs to know the values for various CTAN data fields. For example, for `l3build` itself, the relevant configuration is:

```
uploadconfig = {
  author      = "The LaTeX Team",
  license     = "lppl1.3c",
  summary     = "A testing and building system for (La)TeX",
  topic       = {"macro-sup", "package-devel"},
  ctanPath    = "/macros/latex/contrib/l3build",
  repository  = "https://github.com/latex3/l3build/",
  bugtracker  = "https://github.com/latex3/l3build/issues",
  update      = true,
  description = [[
The build system supports testing and building (La)TeX code, on
Linux, macOS, and Windows systems. The package offers:
* A unit testing system for (La)TeX code;
* A system for typesetting package documentation; and
* An automated process for creating CTAN releases.
]]
}
```

Notice that here we see a little Lua syntax: several strings are placed in the `uploadconfig` *table*, and a multiline string is created using the notation `[[...]]`.

To actually upload using `l3build`, the `ctan` target should be run first to create a .zip file with all relevant data included. The call

```
l3build upload --message "<announcement text>" <version>      or
l3build upload --file <announcement file> <version>
```

can then be used to carry out the upload, with an optional announcement text given either as the argument to the `--message` switch or in a dedicated file. The `<version>`

is optional but would normally be given, because the CTAN maintainers will otherwise query what version string to use for the release.

There are further keys that can be specified as part of the `uploadconfig` data, for example, the name of the `uploader` if it differs from the `author` and an `email` address. The latter is actually required by CTAN, but if your `build.lua` is in a publicly available repository, you may not want to record your e-mail address there to avoid it being picked up by spammers. Therefore, the `l3build` program asks interactively for an `email` address if none is provided.

 *E-mail address
can be specified
interactively*

17.3.4 Common configurations

The standard settings in `l3build` are intended to mean that most package authors need to make only minor adjustments to their setup. As mentioned earlier, the only *required* value is one for `module`. Here, we cover a few common setups that can be accessed easily with `l3build`: for full details of all the settings, see the package documentation [147].

Adjusting the number of runs

When running tests or typesetting documentation, `l3build` uses a fixed set of steps (in contrast to tools such as `latexmk`). Depending on the exact use case, the standard values may not be appropriate.

For tests, the variable `checkruns` controls how many \LaTeX cycles are executed. The standard setting is 1, which is appropriate in many cases but does not allow for any tests that use the `.aux` file or similar. Thus, to check that cross-references are resolved, a setting such as the following is required:

```
checkruns = 2
```

When typesetting, the standard settings run 3 cycles, which includes executing `MakeIndex` and `BIBTEX/biber`. Some more complex documents will need additional runs; e.g., the \LaTeX distribution itself needs¹ this:

```
typesetruns = 4
```

Installing configuration files

Some packages provide multiple configuration files, which often are given the extension `.cfg` or `.def`. These can be included in a generic installation list

```
installfiles = {"*.cfg", "*.def", "*.sty"}
```

or can be listed with their exact file names.

Setting up a larger package with multiple sources

A larger package might also be split into multiple `.dtx` files, each covering part of the functionality. In this scenario, typesetting the programmer documentation is usually

¹The real build script for \LaTeX is more complex: this is an approximation to what happens.

achieved using a file `mypkg-code.tex`, which combines all of the `.dtx` files. The `l3build` setup would then exclude the `.dtx` files, thus

```
typesetfiles = {"*.tex"}
```

or

```
module = "mypkg"
typesetfiles = {module .. ".tex", module .. "-code.tex"}
```

would be appropriate (the `..` syntax joins strings in Lua).

Changing the typesetting engine

By default, `l3build` typesets the documentation using `pdfTEX`, which may not be appropriate, e.g., if you want to make use of features available only in Unicode engines. In that case add an appropriate setting in `build.lua`, e.g.,

```
typesetengine = "lualatex"
```

Separating user and programmer documentation

The `.dtx` format allows separation of the documentation and implementation of a package. However, for larger packages it is often useful to have a document for end users and one aimed at developers. The latter might for example expose a more formalized programmer's API than the user version. This is usually best achieved by having a file `mypkg.tex` for the user documentation, with the text in the “documentation” part of `mypkg.dtx` aimed at developers. This requires that the additional file is included for typesetting:

```
typesetfiles = {"*.dtx", "*.tex"}
```

or if you wish to be more cautious and guard against stray source files, use this:

```
module = "mypkg"
typesetfiles = {module .. ".dtx", module .. ".tex"}
```

Suppressing typesetting of the implementation part

Many package authors include the typeset implementation as part of the documentation. However, this is not always desirable. To suppress the implementation part in the automatically generated PDF, the variable `typesetcmds` is available. The exact string required depends on the document class used in the `.dtx` file. For the standard `ltxdoc` class, the appropriate setting is

```
typesetcmds = "\\AtBeginDocument{\\OnlyDescription}"
```

whereas for `l3doc`, the right setting is

```
typesetcmds = "\\AtBeginDocument{\\DisableImplementation}"
```

Notice that because Lua would interpret a single `\` as an escape sequence, we require `\\` in the setting here.

Creating a ready-to-install “TDS-style” .zip file

For simple packages comprising one .sty file, CTAN prefers a “flat” upload. However, when there is more complexity to a package, for example if it installs multiple files, providing a pre-extracted .zip file (called a TDS-style zip) is useful for end users. This can be enabled by setting

```
packtdszip = true      -- Release a TDS-style zip
```

17.4 Making use of version control tools

When developing a program or writing a large document, such as a user manual or a book (like this one), version control — the task of keeping a software system consisting of many versions and configurations well organized — is an important issue. Over time, several systems have been developed to help with this. These *version control systems* track changes in files. The oldest systems were aimed at individual users, with the idea of a central repository coming later. Even more recently, the concept of *distributed* version control systems has become the most popular: there is not one central machine, rather each user retains a “full” history of a project.

While there have been many version control systems developed since the early 1970s, a few have proved to be particularly popular, in reverse chronological order

- *Git*,¹ originally developed by Linus Torvalds (of Linux fame)
- *Subversion* (SVN)
- The *Concurrent Versions System* (CVS; see <http://www.cvshome.org>)
- The *Revision Control System* (RCS)

Today, Git is probably the most popular choice of version control system for new projects (certainly those that are open source). However, there are very many projects using the other systems, most notably Subversion.

If you put \LaTeX documents under source control, you will often want to have access to the data about the current file or project within your document — perhaps to place the date of the last check-in and the revision number into the running header. There are \LaTeX packages that can help us do that for all of the common version control systems above. Today, it is unlikely you will come across a project using CVS or RCS, so we focus here on support for Git and Subversion.

¹ Not a defined acronym: according to the readme file, Git stands for different things depending on your mood: three random but pronounceable letters, stupid or simple (from the slang dictionary), global information tracker (if it works for you), or g***** idiotic truckload of ... (when it breaks).

17.4.1 gitinfo2 — Accessing metadata from Git

Git does *not* store any revision information in the source files themselves, in contrast to Subversion, CVS, or RCS. This means that placing Git metadata into your document requires running some Git commands “behind the scenes”. The gitinfo2 package written by Brent Longborough (1944–2021) provides a mechanism to extract this information and to then insert it into a L^AT_EX document.

Setting this up needs at least a little familiarity with how Git works. Inside your development directory, there is a (hidden) directory called `.git`, and inside there one called `hooks`: this is where we need to add the necessary scripts. The gitinfo2 package is supplied with a demonstration file called `post-xxx-sample.txt`, which is in the *documentation* tree of your T_EX installation. Perhaps the easiest way to find it is to use `texdoc -l gitinfo2`: this shows all of the “documentation” files for the package, including the full file path to the demonstration script.

You need to make *three* identical copies of the script inside the `.git/hooks` directory. These should be called `post-checkout`, `post-commit`, and `post-merge`, and, if you use macOS or Linux, make them executable using `chmod +x`. After installing the hooks, you may want to run `git checkout` to force them to run; otherwise, there is no metadata available until the next real commit that you make.

Loading the package with the `mark` option inserts a simple “watermark” footer containing key data points:

- the current branch;
- the (short) hash for the most recent commit;
- the most recent release (see below);
- the date of the most recent commit;
- any tags associated with the most recent commit.

All these data elements are available as independent commands to insert into the document (see below), and the overall structure of the watermark is customizable using the `\gitMark` command: this contains the various data-insertion commands and text.

All of the data made available by gitinfo2 is stored in commands with names starting with `\git..` followed by a short descriptive name. For example, the data commands inserted by the standard watermark footer are

- `\gitBranch`
- `\gitAbbrevHash`
- `\gitReln`
- `\gitAuthorDate`
- `\gitTags`

Of these, the only one likely to be unfamiliar to a Git user is `\gitReln`. `gitinfo2` initially assumes that a *release* is associated with a tag that starts with a number and includes a decimal point, for example, 1.4. This definition is part of the script used to extract information from Git, rather than being specified in the \LaTeX code. As such, it can be adjusted by editing the three scripts installed above: this requires knowing a little shell script syntax. The standard definition is

```
RELTAG=$(git describe ... --match '[0-9]*.*' ...)
```

where ... represents parts of the standard definition that do not need our attention here. Changing the argument to `--match` adjusts what is captured: to accept any tag at all as a release, you would use

```
RELTAG=$(git describe ... --match '*' ...)
```

The package provides commands for most other Git metadata, for example, `\gitHash` (the full hash) or `\gitCommitterEmail` (the e-mail address given for the latest commit), etc.

17.4.2 svn-multi — Accessing Subversion keywords in multiple sources

In contrast to Git, Subversion, CVS, and RCS store revision data directly in the source file(s). This works by keyword substitution: there is a specially formatted string inside the sources that is updated by the version control system. All three systems support a common set of the most important keywords: `$Author$` (account of the person doing the check-in), `$Date$` (date and time of check-in in UTC), `$Revision$` (revision number assigned to the check-in), `$Filename$`, and `Id` (combination field, with file name, revision, date, time, author). Initially, one simply adds one or more of these keywords (e.g., `Id`) to the source. Upon first check-in, they are replaced by the structure `$(keyword):␣(value)␣$`, as can be seen in the next example. Later check-ins then update the `(value)` as appropriate.

As with Git-based workflows, you may want to access these keyword values from within a \LaTeX document. Because of the syntax using dollar signs (which indicate formulas in \LaTeX), you cannot use the keywords directly in your text, but there exist packages that provide \LaTeX tags to give you access to this information in a way suitable for typesetting. Here, we cover the `svn-multi` package by Martin Scharrer, because it provides the most flexible and up-to-date interfaces.

There are two set of commands needed to work with SVN keyword data: those to read the information from the source and those to typeset it. In general, SVN keywords are read by the command `\svnkwsave`. The argument to this command *must* start and end with a dollar sign and is interpreted as described above as a keyword and a value (which can be absent). The information is then available to typeset using `\svnkw`.

For example, a date line could be read and then typeset using

```
\svnkwsave{$Date: 2022-01-12 13:34:19 +0100 (Wed, 12 Jan 2022) $}
Date \svnkw{Date}.
```

Most commonly, files tracked by SVN use the `Id` keyword, which contains multiple data items. This is given therefore special handling by `svn-multi`, which can save the information using the command `\svnid`. This information is then available immediately for typesetting using `\svnkw`. Shortcuts for the author, date, time, and revision number are available as `\svnauthor`, `\svndate`, `\svntime`, and `\svnrev`. This (global) information is available only during a second or subsequent L^AT_EX run; we will see why shortly.

Information is directly available using `\svnkw`: the file `test.tex` has revision number 6, last checked in by Frank on 2022-01-12 13:34:19Z.

Global information is available during a second L^AT_EX run: the global revision number is 6, with the last check-in was made by Frank on 2022-01-12 13:34:19Z at 13:34:19 UTC (we might refer to it as January 12, 2022).

```
\usepackage{microtype,svn-multi}
\svnid{$Id: test.tex 6 2022-01-12 13:34:19Z Frank $}
Information is directly available using
\verb"\svnkw": the file \svnkw{Filename} has revision
number \svnkw{Revision}, last checked in by
\svnkw{Author} on \svnkw{Date}.
```

```
Global information is available during a second
\LaTeX{} run: the global revision number is \svnrev{},
with the last check-in was made by \svnauthor{} on
\svndate{} at \svntime\,\textsc{utc} (we might refer
to it as \svntoday{}).
```

17-4-1

The reason for the existence of two interfaces for typesetting SVN keyword information is that `svn-multi` is able to handle more complex scenarios. In particular, for a project of any scale, each file will have its own revision information when using SVN. Thus, at any point in a document you might wish to typeset the global revision information for the entire project, the specific information for the current source, or of course both. Data for the current file are available using a parallel set of typesetting commands starting with `\svnfile...`, so for example the revision of the current file is `\svnfilerev`. Normally, the main file is the first one in which `\svnid` occurs, but this can be adjusted using the command `\svnsetmainfile`. This is the reason that `\svnid`, etc., require two runs to print values: on the first L^AT_EX run, it is possible that the main file is set *after* the first typesetting calls.

The package allows further control of keyword scope by providing *grouping* of source files. Within a group of files, data items are available for the current group, so `\svncgrev` is the revision number of the current group. Groups are created manually, by using the `\svngroup` command with a *group name* as the mandatory argument. The group then continues until the next occurrence of `\svngroup` or the end of the current file: the latter restrictions ensure that parent files are not affected by a group setting in a child file.

The `svn-multi` package provides a number of commands for customizing the appearance of date/time values. We have seen above that `\svntoday` prints the

value of `\svndate` in the format of `\today`. Each part of the date and time is available as a separate command, for example `\svnday` for the global revision day or `\svnfiletimezone` for the time zone of the current file.

The way that author names are printed can also be adjusted, with the command `\svnRegisterAuthor`, available to map the author name in the SVN data to a full name for typesetting. For example

```
\svnRegisterAuthor{Frank}{Frank Mittelbach}
```

would then allow

```
\svnFullAuthor{\svnauthor}
```

to print “Frank Mittelbach” rather than just “Frank”. Notice that `\svnFullAuthor` expands its argument to text before looking up the name: we could have used the literal `Frank` or another command such as `\svnfileauthor` and gotten the same effect.

17.4.3 filemod — Printing or checking file modification dates

This is not exactly part of version control, but sometimes it is helpful to document the modification date (or time) of a file or compare it with some other date or time. For this Martin Scharrer produced the little package called `filemod`.

The example below first defines two files using the `filecontents` environment. The first of them is always regenerated, while the second is generated only once; thus if you run the example several times (as we do during book generation), it becomes the older of the two.

As usual, one can leave out the extension, in which case `.tex` is assumed. Several of the commands provided by the package are expandable, a fact we use to load the oldest and later the newest file at the end, to exhibit the mechanism:

```

\usepackage{filemod}
\begin{filecontents}[force]{trial1}
  content Trial1 % rewritten always!
\end{filecontents}
\begin{filecontents}{trial2}
  content Trial2 % written once!
\end{filecontents}

Date: 2022/12/28
Time: 13:33:47 +01'00'
trial1.tex: 2022/12/28 13:33:47 +01'00'
trial2.tex: 2022/07/17 18:13:53 +02'00'

Oldest: content Trial2
Newest: content Trial1
\usepackage{filemod}
\begin{filecontents}[force]{trial1}
  content Trial1 % rewritten always!
\end{filecontents}
\begin{filecontents}{trial2}
  content Trial2 % written once!
\end{filecontents}
Date: \filemodprintdate{trial1.tex} \\
Time: \filemodprinttime{trial1.tex} \\[10pt]
trial1.tex: \filemodprint{trial1} \\
% second file (written only once):
trial2.tex: \filemodprint{trial2} \\[10pt]
Oldest: \input{\filemodoldest{trial1}{trial2}} \\
Newest: \input{\filemodnewest{trial1}{trial2}}
```

This is mainly a teaser so that you know the functionality is available. The package provides a large number of additional commands to adjust results, store them, or do more complex comparisons, e.g., compare large lists of files to select the newest or oldest, etc. For details, see the package documentation.

APPENDIX A

L^AT_EX Overview for Preamble, Package, and Class Writers

A.1 Linking markup and formatting	622
A.2 Counters and length expressions	646
A.3 Page markup — Boxes and rules	660
A.4 L ^A T _E X's hook management.	671
A.5 Control structure extensions	685
A.6 Package and class file structure	693

This appendix gives an overview of the basic programming concepts underlying the L^AT_EX formatter. We explain how to define new commands and environments, including those with optional arguments and other specialized input syntax. We discuss how L^AT_EX handles counters and their representation; we also introduce horizontal and vertical space parameters and explain how they are handled.

The third section reviews the important subject of L^AT_EX boxes and their use. A good understanding of this topic is very important to fully appreciate and exploit the information presented in this book.

In the fourth section we then take a deeper look at L^AT_EX's new hook management that was introduced in 2020. The fifth section is devoted to two package files, `calc` and `ifthen`, that make calculations and building control structures with L^AT_EX easier. They have been used in many examples of L^AT_EX code throughout this book.

Finally, we describe in detail the L^AT_EX interfaces that allow you to define your own packages and class files.

A.1 Linking markup and formatting

This section reviews the syntax for defining commands and environments with L^AT_EX. It is important that you exclusively use the L^AT_EX constructs described below, rather than the lower-level T_EX commands. Then, not only are you able to take advantage of L^AT_EX's consistency checking, but your commands are also portable, (probably) without modification, to future versions of L^AT_EX.

L^AT_EX offers three major ways to define commands and environments. Simple commands can be defined with `\newcommand` and `\newenvironment` that have been available for several decades. These are discussed first.

More recently the `\NewDocumentCommand` and `\NewDocumentEnvironment` declarations were added to L^AT_EX. They allow you to easily define commands and environments with a richer argument structure, not only involving a single optional argument, but also those with multiple optional arguments, special argument delimiters, and much more. This is discussed in Section A.1.4 on page 632.

Finally, there are low-level methods of T_EX, through `\def`, `\let`, and similar commands, and, of course, all the declarations from the L3 programming layer (formerly known as `expl3`), e.g., `\cs_new:Npn` and many more. None of that is covered in this book because these constructs should be used only for low-level programming, and their discussion would easily fill a book by itself.

A.1.1 Command and environment names

Commands

In current L^AT_EX, whether used with pdfT_EX or with one of the Unicode engines, it is possible to enter accented characters and other non-ASCII symbols directly into the source, so it would seem reasonable to expect that such characters could also be used in command and environment names (e.g., `\größ̈er`). However, this is not the case — L^AT_EX multicharacter command names should be built from basic ASCII letters (i.e., `a...z` and `A...Z`).¹ This means that `\vspace*` is actually not a command by itself; rather, it is the command `\vspace` followed by the modifier `*`. Technically, you could write `\vspace_*` (as the space is ignored) or even put the `*` on the next line of your document.²

Environments

On the other hand, names of environments are different. In this case the `*` is part of the name, and spaces preceding it are not ignored. Thus, when writing something like `\begin{figure_*}`, the space would become part of the name, and this is therefore not recognized as the start of a `figure*` environment. This is due to implementation details and seems to indicate that with environment names some additional ASCII characters work. For example:

```
\newenvironment{foo.bar:baz_with_space}{}{}
```

However, this is not true in general because, depending on additional packages being

¹Strictly speaking this is not true, as T_EX can be configured to support other configurations. There are, however, valid reasons why this is not being done for standard L^AT_EX. Some of these reasons are discussed in Section 9.9 describing L^AT_EX's encoding model.

²It is bad style to use this in your documents, but there is unfortunately no way to prevent it.

loaded, such environment names may no longer be recognized or may produce strange errors. Thus, it is best not to explore that implementation (mis)feature and instead to rely on officially supported names — those containing only lowercase and uppercase letters and the star character.

Strictly speaking, `\cite` and `\label` keys have (or had) the same kind of restriction. Nevertheless, it has become common practice to use keys containing colons (e.g., `sec:cmds`) so that most packages provided extra support to allow for at least the colon character in such keys. Around 2020, when \LaTeX moved to UTF-8 as its default input, that restriction was lifted as part of the necessary rewrite so that now most characters outside the ASCII range can be safely used in label keys. However, characters used in \LaTeX 's syntax (e.g., `$`, `_`, or `#`) can never be used in names, whether they are keys, counters, environments, or multicharacter command names.

*Citation and
label keys*

With single-character command names, the situation is different again: any (single) character can be used. Symbols that are not “letters” cannot participate in multiletter command names, e.g., `\foo$bar` would be interpreted as the command `\foo` followed by the start of a math formula (signaled by `$`) followed by the (math) characters `b`, `a`, and `r`. Any following text is then also typeset in math mode. However, such symbols can appear directly after the backslash and form a so-called control symbol; e.g., `\$` is perfectly valid.

Control symbols

In contrast to multiletter commands, such control symbols do not ignore spaces after them, because that is what is normally desired in situations like `30\%` or `cut \& paste`. Note, however, that something like `\S` would not be a control symbol but a multiletter command, consisting of a name with only a single letter and thus spaces are ignored after it, as shown in the following example:

<div data-bbox="114 984 178 1014" data-label="Text" style="border: 1px solid black; padding: 2px; display: inline-block;">A-1-1</div>	<p><code>\$ 100</code> is different from <code>\$100</code>. You have to write <code>\$100</code> to avoid the space!</p> <p>But <code>§1.2</code> and <code>§1.2</code> give the same spacing.</p>	<p><code>\\$ 100</code> is different from <code>\textrm{\\$} 100</code>. You have to write <code>\\$100</code> to avoid the space!</p> <p>But <code>\S 1.2</code> and <code>\S1.2</code> give the same spacing.</p>
---	---	---

Categories of \LaTeX commands

\LaTeX commands (i.e., those constructs starting with a backslash) are classified into three basic categories: document-level commands, package and class writer commands, and internal “kernel” commands.

- Document-level commands, such as `\section`, `\emph`, and `\sum`, usually have (reasonably) short names, by convention all in lowercase.
- Class and package writer commands, by convention, have longer mixed-case names, such as `\InputIfFileExists` and `\RequirePackage`. Some of them can be usefully applied in the document source, but many stop working after `\begin{document}` has been processed, producing an error message if you try.
- Traditionally most of the internal commands used in the \LaTeX implementation, such as `\@tempcnta`, `\@ifnextchar`, and `\z@`, contain `@` in their name. This effectively prevents these names from being used in documents for user-defined commands. However, it also means that they cannot appear in a document, even in the preamble, without taking special precautions.

*Document-level
commands*

*Class and package
writer commands*

*Internal \LaTeX
commands*

Modern internal commands use the L3 programming layer where commands use “_” and “:” as part of their names, which makes them also (deliberately) unusable in documents.

Careful
with internal
commands!

As a few of the examples in this book demonstrate, it is sometimes necessary to have such bits of “internal code” in the preamble. The commands `\makeatletter` and `\makeatother` make this easy to do; the difficult bit is to remember to add them — failure to do so can result in some strange errors. For an example of their use, see page →I 210. Note that package and class files should never contain these commands: `\makeatletter` is not needed because this is always set up when reading such files, and the use of `\makeatother` would prematurely stop this behavior, causing all kinds of havoc. For modern L3 programming layer code (`expl3`), there are `\ExplSyntaxOn` and `\ExplSyntaxOff` that serve the same purpose.

The distinction
between internal
and public
commands

Unfortunately, for historical reasons the distinction between these categories is often blurred. For example, `\hbox` is an internal command that should preferably be used only in the L^AT_EX kernel, because it does not deal properly with color changes in its argument, whereas `\m@ne` is the constant `-1` and would have been better named `\MinusOne` back then.

Nevertheless, this rule of thumb is still useful: if a command has `@` in its name, then it is not part of the supported L^AT_EX language — and its behavior may change in future releases! Any such command should be used with great care. On the other hand, mixed-case commands or those described in the *L^AT_EX Manual* [106] are guaranteed to be supported in future releases of L^AT_EX.

In the L3 programming layer there is much more standardization. Command names follow a predictable pattern, and what is supported and usable elsewhere is well defined: any name starting with `_` is private and should not be used outside its module; all others are officially part of the programming layer. Similarly, private (local) variables start with `\l_`, whereas public ones have only one underscore, etc.

A.1.2 Defining simple commands

It is often advantageous to define new commands (e.g., for representing repetitive input strings or recurring combinations of commands). Here we describe how to do this for simple cases, where the new commands take at most one optional argument. This is the method introduced with L^AT_EX 2_ε in 1994. How to define commands with more complex argument structures is shown in Section A.1.4.

Complexity comes with a price tag in terms of processing speed: so for “simple” tasks we recommend simple tools, i.e., the declarations discussed here. However, already when defining commands with one optional argument, you should consider using the declarations discussed later.

`\newcommand{cmd}[narg]{code}`

A new command is defined using the `\newcommand` declaration. The number of arguments is in the range $0 \leq narg \leq 9$. If your new command has no arguments,

then the `[0]` can be omitted. Inside the *code* part, the arguments are referenced as `#1` to `#⟨narg⟩`.

PostScript and its variant Encapsulated PostScript are often used for including graphics in \LaTeX documents ...

```
\newcommand{\PS}{Post\-\Script}
\newcommand{\EPS}{Encapsulated \PS}
\PS{} and its variant \EPS{} are often used for
including graphics in \LaTeX{} documents \ldots
```

A-1-2

The *cmd* argument always has to contain a single “token” (the name of the command to be defined), so one can omit the braces around this argument. While we do not recommend the use of this \TeX syntax feature in other places, it is commonly used with `\newcommand` and similar declarations. In fact, we have often used this more concise syntax in this book:

*Omitting argument
braces*

```
\newcommand\PS{Post\-\Script}    \newcommand\EPS{Encapsulated \PS}
```

Note, however, that this is possible only with arguments that are single tokens to \TeX (i.e., names starting with a backslash). Trying to do the same with, for instance, environment or counter names will fail. For example,

```
\setcounter mycount {5}          \newenvironment myenv{...}{...}
```

is invalid \LaTeX syntax.

If a command should work both in math mode and in text mode, special care should be taken in its definition. One could, for example, use `\mbox`, but this has a number of drawbacks.

The series of x_1, \dots, x_n or $x_1, \dots, x_n + G_{x_1, \dots, x_n}$ — but this definition does not change its size if used in the subscript position.

```
\newcommand\xvec{\mbox{$x_1, \ldots, x_n$}}
The series of \xvec\ or $\xvec+G_{\xvec}$ ---
but this definition does not change its size
if used in the subscript position.
```

A-1-3

A better solution is offered by the \LaTeX 2_ϵ command `\ensuremath`. As the name implies, `\ensuremath` ensures that its argument is always typeset in math mode by surrounding it, if necessary, with `$` signs. Thus, the definition in the above example should be replaced as follows:

The series of x_1, \dots, x_n or $x_1, \dots, x_n + G_{x_1, \dots, x_n}$ — both work well with the new definition.

```
\newcommand\xvec{\ensuremath{x_1, \ldots, x_n}}
The series of \xvec\ or $\xvec+G_{\xvec}$ ---
both work well with the new definition.
```

A-1-4

This has the additional advantage of producing correctly sized symbols in subscripts or superscripts, which is not the case if an `\mbox` is used in the definition.

Existing commands must be *redefined* with the command `\renewcommand`, which otherwise has the same syntax as `\newcommand`. Note that you can redefine a command with a different number of arguments than the original one has (though

that is seldom a good idea). Therefore, you could redefine the `\xvec` command of the above example so that it now takes two arguments:

The series of x_1, \dots, x_n or $x_1, \dots, x_n + G_{x_1, \dots, x_n}$	<code>\newcommand\xvec{\ensuremath{x_1,\ldots,x_n}}</code> The series of <code>\xvec\</code> or <code> \$\xvec+G_{\xvec}\$ \par</code> <code>\renewcommand\xvec[2]{\ensuremath{\#1_1,\ldots,\#1_{\#2}}}</code> The series of <code>\xvec{x}{n}</code> or <code> \$\xvec{y}{k}+G_{\xvec{z}{4}}\$</code>
---	---

A-1-5

When redefining a command (or an environment — see below), you must, of course, be cautious. It is good practice to do that only to commands that you have defined yourself earlier. Overwriting commands defined by packages or the L^AT_EX kernel may be temporarily necessary if they have bugs, but it is likely to break their usage in places you do not control, and even if the redefinition works initially, subsequent corrections or updates to L^AT_EX or the package providing the initial definition may render your redefinition suddenly invalid.

Commands with one optional argument

With `\newcommand` you can also define commands so that their first argument is optional. The syntax for this is

```
\newcommand{cmd}[narg][default]{code}
```

An example of such a command definition is shown below:

```
\newcommand\LB[1][3]{\linebreak[#1]}
```

The default for the optional argument is given between the second pair of square brackets — the string “3” in this case. Inside the command definition, the optional argument has the number `#1`, while the mandatory arguments (when present) are addressed `#2` to `#(narg)`. Thus, typing `\LB` is a short way of saying `\linebreak[3]`, while `\LB[2]` uses the actual specified value. That is, you obtain the same effect as when typing `\linebreak[2]`.

New commands that have only mandatory arguments are expandable, i.e., they are replaced by their definition if used in moving arguments (for example inside `\section`), while those that are defined with an optional first argument are automatically made robust, i.e., they do not expand in such places.

In the next example we define the command `\lvec`, which can be used inside or outside of formulas (due to `\ensuremath`). Under the assumption that the upper subscript is usually n we made it optional, while the vector variable has to be given explicitly.

For the series $x_1 + \dots + x_n$ we have

$$x_1 + \dots + x_n = \sum_{k=1}^n G_{y_1 + \dots + y_k}$$

```
\newcommand\lvec[2][n]
{\ensuremath{\#2_1+\cdots+\#2_{\#1}}}
For the series \lvec{x} we have
\[ \lvec{x} = \sum_{k=1}^n G_{\lvec{k}{y}} \]
```

A-1-6

In general, it is most practical to associate the case that occurs most often with the form that does not need the optional argument and to represent the cases that are used less often with longer command strings with an optional argument.

Argument restrictions for simple commands

As explained above, user-defined commands can have one optional argument and up to nine arguments in total. If defined with `\newcommand`, each of the arguments can receive arbitrary text with a small number of restrictions:

- Braces must be properly balanced because otherwise \TeX is unable to determine where the argument ends.
- In an optional argument a closing bracket “]” is allowed only if hidden inside braces (e.g., `\item[{a}]` is allowed). Without the braces the first] would be misinterpreted as the end of the optional argument.¹
- The `\verb` command, the `verbatim` environment, and related commands or environments are not supported within arguments of other commands.

The allowed content of arguments can be deliberately further restricted by using the `\newcommand*` variant of the declaration.

Disallowing `\par` in argument content

```
\newcommand*{cmd}[narg][default]{code}
```

The starred form works like `\newcommand` but defines a *cmd* that is not, in \TeX terms, long. This means that the newly defined command does not accept empty lines or `\par` commands in its argument(s). This restriction can be useful for commands whose arguments are not intended to contain whole paragraphs of text.

Commands that have been defined with the low-level \TeX primitive `\def` do not accept `\par` in their argument. Thus, they are equivalent to being defined with `\newcommand*`. The low-level \TeX equivalent to `\newcommand` is `\long\def`, except that neither can be used to define a command with an optional argument.

 *Relation to \TeX primitives*

Nesting new commands in each other

Sometimes it is necessary to nest command definitions, most commonly in the combination of commands being defined as part of the definition of some new environment. If the inner command (or environment) has arguments, there is a problem referring to them. Clearly we cannot use `#1`, `#2`, and so on, because this notation already denotes the argument(s) of the outer command or environment. The \TeX solution is to double the hash marks; thus, `##1` would refer to the first argument of the inner definition, and in the case of three nested definitions we would need `###1`, and so on.

¹This restriction is removed if the declarations from Section A.1.4 are used instead — as long as the [...] come in matching pairs.

To make this abstract concept a bit clearer, we define a command `\DEF\vec` that (re)defines the `\lvec` command from Example A-1-6 on page 626 over and over again. As a first argument to `\DEF\vec` we pass the vector name that is being hardwired into the redefinition of `\lvec`. As the second argument we pass the upper index that becomes the default value for the optional argument of `\lvec`. Thus, since the vector name is now part of the definition, `\lvec` has only an optional argument.

```
\newcommand\lvec{}
\newcommand\DEF\vec[2]{\renewcommand\lvec[1][#2]%
    {\ensuremath{#1_1+\cdots + #1_{##1}}}}
\DEF\vec{x}{n} % initial definition
```

Default: $x_1 + \cdots + x_n \neq x_1 + \cdots + x_k$

Now: $y_1 + \cdots + y_i \neq y_1 + \cdots + y_k$

Default: $\$ \lvec \neq \lvec[k] \$ \par$

`\DEF\vec{y}{i}` Now: $\$ \lvec \neq \lvec[k] \$$

A-1-7

The technique used in the above example is worth studying. Try to visualize the actual definitions being carried out, for example, when the “initial definition” is executed. Also note the need for a top-level definition for `\lvec`: the actual definition is irrelevant, but without it we would be unable to “redefine” it inside the `\DEF\vec` command. The `\ShowCommand` described on page 767 is a good way to look at the results.

Special declarations for use in packages and classes

Besides `\newcommand` and `\renewcommand`, which were originally provided as user commands (e.g., for the document preamble), L^AT_EX offers some extra methods of (re)defining commands that are intended for use in class and package files.

```
\providecommand*{cmd}[narg][default]{code}
```

This declaration works exactly like `\newcommand` and `\newcommand*`, except that it is ignored if the command to be defined already exists. Such a feature is useful in sources that may get used in several documents, such as bibliography entries. For example, instead of using `\newcommand` in the `@preamble` of B_BL_AT_EX for logos and other constructs used in the B_BL_AT_EX entries, you can use `\providecommand` to avoid error messages if such commands are already defined in the document.

```
\DeclareRobustCommand*{cmd}[narg][default]{code}
```

This command takes the same arguments as `\newcommand` and `\newcommand*` but declares a robust command, even if some code within the `code` argument is fragile. You can use this command to define new robust commands, or to redefine existing commands *and* make them robust. Information is placed into the transcript file if `cmd` is redefined, so it does not produce an error in this case. In the case an existing fragile command should be made robust without otherwise changing it, L^AT_EX offers `\MakeRobust\cmd`, which is used in various places in the kernel.

```
\CheckCommand*{cmd}[narg][default]{code}
```

This command takes the same arguments as `\newcommand` and `\newcommand*` but, rather than defining *cmd*, checks that the current definition of *cmd* is exactly as given by *code*. A warning is raised if the definitions differ or if one accepts `\par` in its arguments and the other does not (i.e., was defined using a starred form). This command is useful for checking the state of the system before a package starts altering the definitions of commands. It allows you to check, in particular, that no other package has redefined the same command.

A.1.3 Defining simple environments

You can define and redefine an environment with the `\newenvironment` and `\renewenvironment` commands, respectively. You must specify, in each case, which actions should take place when you enter and leave an environment. For an environment called “myenv” this is signaled by the commands `\begin{myenv}` and `\end{myenv}` inside your document.

```
\newenvironment{name}[narg]{begin code}{end code}
\renewenvironment{name}[narg]{begin code}{end code}
```

As with the `\newcommand` declaration, the number of arguments is in the range $0 \leq narg \leq 9$. In the case of no parameters, you can omit `[0]`. Inside the definition part, *begin code*, these parameters are referenced as `#1` to `#<narg>`. If arguments are present, then they are defined when *entering* the environment by specifying them on the command `\begin{name}`, as shown below:

```
\begin{name}{arg1}\dots{argnarg} \dots body \dots \end{name}
```

When *exiting* an environment with the command `\end{name}`, no parameters can be specified. Moreover, the parameters specified with the `\begin{name}` command when entering the environment (see above) are no longer available in the definition part *end code*, where you define the actions that should take place when leaving the environment. This means that it is your responsibility to store information needed at the end of an environment (see the `Citation` environment defined below).¹

Technically, a `\newenvironment` declaration for the environment *name* defines a command `\name` that is called during the `\begin{name}` processing and a command `\endname` that is executed (besides other things) by `\end{name}`. You may find that it is sometimes these commands rather than the environment tags that are used inside packages and classes to define related environments or commands. An example where this might be useful is given on page 131. In other situations, it is not advisable to follow this practice without a thorough understanding of L^AT_EX’s kernel implementation and in particular its environment hooks (which are then missing).

 *Arguments not available in end-tag*

¹Again, this restriction is lifted if you use the declarations discussed in Section A.1.4 instead.

Our first example defines an environment of type “Abstract”, which is often used to give a short summary of the contents of an article or a book. It starts by typesetting a boldfaced and centered title, followed by the text of the abstract inside a quote environment. The final `\par` command ensures that any following text starts a new paragraph with a normal paragraph indentation.

Abstract

This abstract explains the approach used to solve the problems at hand.

Some text following the abstract. Some text following the abstract. And some more.

```
\newenvironment{Abstract}
  {\begin{center}\normalfont\bfseries Abstract%
  \end{center}\begin{quote}}{\end{quote}\par}

\begin{Abstract}
  This abstract explains the approach used
  to solve the problems at hand.
\end{Abstract}

Some text following the abstract. Some text
following the abstract. And some more.
```

A-1-8

Our second example is somewhat more complex. It shows how a Citation environment can be defined for quoting citations by famous people. In the document it would be used as follows:

Citation 1 Man is the measure of all things.

Protagoras

This is some regular text in between two Citation environments.

Citation 2 On mourra seul.

Blaise Pascal

More regular text ...

Citation 3 Necessity is the plea for every infringement of human freedom.

William Pitt

```
\begin{Citation}{Protagoras}
  Man is the measure of all things.
\end{Citation}

This is some regular text in between two
Citation environments.

\begin{Citation}{Blaise Pascal}
  On mourra seul.
\end{Citation}

More regular text \ldots

\begin{Citation}{William Pitt}
  Necessity is the plea for every
  infringement of human freedom.
\end{Citation}
```

A-1-9

The L^AT_EX code for the Citation environment is shown on the opposite page. We start by declaring the counter `Citctr`, for numbering the citations, and a box `\Citname`, for storing the name of the person whom we are citing so that we can typeset it at the end of the citation when the `\end{Citation}` command is encountered (remember that the value of the argument specified on the `\begin{Citation}` command is no longer available at that stage).

When entering the environment, we save the value of the argument, typeset in italic, in the box `\Citname` and increment our counter. We then start a description environment. This environment has a single `\item` containing the counter value preceded by the word “Citation”.

When exiting the Citation environment, we twice issue a stretchable horizontal space separated by an allowed — but discouraged — line break. It is important that this space survives if a line break happens before or after it, so `\hspace*` is used.

We also throw in a `\quad` of space that ensures a proper separation between the citation and the name if they appear on the same line, but vanishes if a break is taken between them. Then we typeset the contents of the box `\Citname` before leaving the `\description` environment. This puts the author's name flush right and the last line of the citation flush left, regardless of whether they end up on separate lines, as you can see in the next example. Without this adjustment the text of the citation would always be fully justified, often with a lot of white space between the words. For a discussion of the counter and box commands used in this example, see Sections A.2.1 and A.3.

```
\newcounter{Citctr} \newsavebox{\Citname}
\newenvironment{Citation}[1]
  {\sbox\Citname{\emph{#1}}\stepcounter{Citctr}%
   \begin{description}\item[Citation \arabic{Citctr}]}
  {\hspace*{\fill}\nolinebreak[1]\quad\hspace*{\fill}%
   % \finalhyphendemerits=0 % <--- see text below
   \usebox{\Citname}%
   \end{description}}
```

Surprisingly, the name in the last citation of Example A-1-9 is typeset on a line of its own, even though there is clearly enough space to place it alongside the citation. The reason is that T_EX's paragraph-breaking algorithm prefers solutions that do not have the second-to-last line ending in a hyphen and therefore selects a three-line paragraph breaking at the `\nolinebreak`.

There are two ways to correct this behavior. First, we can discourage breaking at this point by using an optional argument of `[3]` instead of `[1]`, which would work in that particular example but may not work always. Second, we can tell T_EX's algorithm not to take that hyphen into account by setting the low-level T_EX integer parameter `\finalhyphendemerits` to zero. This requires a somewhat unusual syntax, as shown in the example code above (though commented out there to display the behavior without it).

§ A hyphen on the
second-to-last line
of a paragraph

```
\newenvironment{name}[narg][default]{begin code}{end code}
```

As with `\newcommand`, one can make the first argument of an environment optional. The *default* value for the optional argument is given between the second pair of square brackets. Inside the *begin code* part, which is executed when the environment *name* is entered, the optional argument can be accessed with `#1`. The mandatory arguments (when present) are addressed as `#2` to `#<narg>`. When the *name* environment is used without an optional parameter, `#1` contains the string specified as *default*.

As an example, we implement an `altDescription` environment with an optional argument that is trial-typeset to determine the width of the indentation. The list labels are placed flush right if possible (by placing `\hfil` at the left in `\makelabel`). When used without an optional argument, the indentation is `1em` (i.e., a `\quad`). By specifying the widest entry as an optional argument, you make sure that the description parts of all your entries line up nicely.

The example first shows the (default) behavior of the `altDescription` list and then displays what it looks like when using the optional argument.

	<pre>\usepackage{calc} \newenvironment{altDescription}[1][\quad] { \begin{list}{}{} \renewcommand\makelabel[1]{\hfil\textsf{##1}} \settowidth\labelwidth{\makelabel{#1}} \setlength\leftmargin{\labelwidth+\labelsep} }{\end{list}}</pre>
First	This is a short term with text that wraps.
Long term	This is a long term.
Even longer term	A very long term.
First	This is a short term with text that wraps.
Long term	This is a long term.
Even longer term	A very long term.

A-1-10

A.1.4 Defining more complex commands and environments

With `\newcommand` and `\newenvironment` it is possible to define simple commands and environments, and in many cases this is sufficient. However, if you look at the commands offered by L^AT_EX and the packages described in this book, you find many commands with complex argument structures, e.g., with multiple optional arguments, special argument delimiters, and much more. In the past all such commands needed to be hand-crafted with low-level methods. While one can learn how to do this, it is challenging, and it is not something an author can do in the preamble of a document.

For this reason the L^AT_EX Project Team developed a generalized specification facility that allows you to easily set up commands with complex arguments covering all of L^AT_EX standard syntax possibilities and several additional features that go way beyond. This was first distributed as the package `xparse`, and since 2020, it is part of the L^AT_EX format. The declarations for this and the underlying concepts are discussed in this section.

First, we describe the different argument types and then move on to explain how they can be used to create both document commands and environments. Finally, more specialized features are described, which allow an even richer application of a simple interface setup.

Describing argument types

If you want to specify different kind of arguments, it is no longer enough to know the number of arguments for a function; in addition, you need to know the nature of each of the arguments. This is done by constructing an *argument specification* that defines implicitly the number of arguments and explicitly the type of each argument and any

additional information needed for a parser to read the user input and properly pass it through to internal functions.

The basic form of the argument specification is a list of letters, where each letter denotes a type of argument. Some of the types need additional information, such as default values or delimiters. A maximum of nine “argument” letters is supported.

The argument types can be divided into two groups, those that define arguments that are mandatory (raising an error if not found) and those that define optional arguments and thus are allowed to be missing in the input. The mandatory types are the following:

Types denoting mandatory arguments

m A standard mandatory argument, which can be either a single token alone or multiple tokens surrounded by braces `{ . . . }`. Regardless of the input format, the argument is passed to the internal code without the outer braces. This is the type specifier for a normal \TeX argument.

r $\langle token_1 \rangle \langle token_2 \rangle$ This denotes a delimited mandatory argument, where the delimiters are $\langle token_1 \rangle$ and $\langle token_2 \rangle$. If the opening delimiter $\langle token_1 \rangle$ is missing, an error is raised, and the special default marker `-NoValue-` is used as the argument value.

R $\langle token_1 \rangle \langle token_2 \rangle \{ default \}$ This too is a required delimited argument. Compared to **r**, the *default* instead of `-NoValue-` is used when the argument is missing.

v This type specifies an argument that is read “verbatim”. In the document it is delimited by an arbitrary character (except for `%`, `\`, `#`, `{`, `}`, or `_`) and its next occurrence, in the same way as the argument of the \LaTeX command `\verb`. As an alternative, the argument can be given in a brace group `{ . . . }`, which is not possible with \LaTeX ’s `\verb`.

To help with error recovery, v-type arguments have to be given on a single line in the document source and raise an error if that is not the case.

A command with one or more v-type arguments produces an error when it appears within an argument of another command or environment.

b This type is suitable only in the argument specification of an environment and denotes the body of the environment, i.e., the material between `\begin{env}` and `\end{env}` in the source. If used, it has to be the last argument specified. See page 641 for details on its use.

The types that define optional arguments are:

Types denoting optional arguments

o A standard \LaTeX optional argument, surrounded with square brackets, that returns the special `-NoValue-` marker if not given (as described later).

d $\langle token_1 \rangle \langle token_2 \rangle$ Like **o**, but the argument is delimited by $\langle token_1 \rangle$ and $\langle token_2 \rangle$.

O $\{ default \}$ Like **o**, but returns $\langle default \rangle$ if no value is given.

D $\langle token_1 \rangle \langle token_2 \rangle \{ default \}$ Like **d**, but returns $\langle default \rangle$ if no value is given.

Internally, the **o**, **d**, and **O** types are shortcuts to an appropriately constructed **D** type argument.

s Scan for an optional star, which results in a value `\BooleanTrue` if a star is

present and `\BooleanFalse` otherwise. These return values can be tested with `\IfBooleanTF` as described later.

`t(token)` Like `s`, but scans for an optional *token*; i.e., `s` is a shorthand for `t*`.

`e{token1token2...}` This defines a number of optional “embellishment” arguments, one for each *token_i*. The tokens must be distinct. In the document they are given as *token_i{value}*, and they can appear in any order at that point in the argument list.

A premier example is subscripts and superscripts in math, which are represented by `_ {value}` and `^ {value}` in the document and can be written there in any order without changing the result. They can be modeled with an `e`-type by specifying `e{^_}`. This would then define two optional arguments. If present in the document, they receive the *values* given there; if not, they return the special marker `-NoValue-`, which the code could then test for to execute a special action. The order in which the values accessed in the code (`#(number)`) is the order in which the *tokens* are specified, not the order in which they appear in the document. See page 640 for further details.

`E{token1token2...}{default1}{default2...}` Same as the `e`-type but with explicit default values instead of `-NoValue-` if not all embellishments are present in the document. You may specify fewer defaults than tokens. See page 641 for further details.

Modifying argument types In addition to the argument *types* discussed above, the argument specification also gives special meaning to three other characters:

- + The `+` character is used to make an argument long (to accept `\par` in the argument). In contrast to `\newcommand`, this applies on an argument-by-argument basis. Thus, specifying `soo+m0{default}` means that the mandatory argument is `\long`, while the optional arguments are not.
- ! The `!` character is used to control whether spaces are allowed before optional arguments in the source. There are some subtleties to this, because T_EX itself has some restrictions on where spaces are automatically ignored: more detail is given on page 638. It can also be used with the mandatory `b`-type, where it has a slightly different meaning as described on page 642.
- >{processor} Finally, the character `>` is used to declare so-called “argument processors” that can be used to modify the contents of an argument before it is passed to the macro definition. The use of argument processors is a somewhat advanced topic (or at least a less commonly used feature) and is covered on page 642.

To give some first examples, `\newcommand\foo[3]{...}` would correspond to the argument specification `+m+m+m` (three mandatory arguments all accepting `\par`) and `0{bar}m` (one optional argument with default value `bar` followed by a mandatory one) would correspond to `\newcommand*\foo[2][bar]{...}`. To improve the readability of an argument specification you can put spaces between the argument specifiers, but you still need to make sure that you do not have spurious spaces in the *code* argument (unless you program using the L3 programming layer).

Creating document commands and environments

To declare commands with argument specifications as discussed above, the following family of declarations is available:

```
\NewDocumentCommand{cmd}{arg spec}{code}
\RenewDocumentCommand{cmd}{arg spec}{code}
\ProvideDocumentCommand{cmd}{arg spec}{code}
\DeclareDocumentCommand{cmd}{arg spec}{code}
```

The argument specification for the function is given by *arg spec*, and the command uses the *code* with #1, #2, etc., replaced by the arguments found by the parser. The difference between the declarations is the behavior if *cmd* is already defined:

- `\NewDocumentCommand` issues an error if *cmd* has already been defined.
- `\RenewDocumentCommand` in contrast issues an error if *cmd* has not previously been defined.
- `\ProvideDocumentCommand` creates a new definition for *cmd* only if one has not already been defined and otherwise does nothing.
- `\DeclareDocumentCommand` always creates the new definition, regardless of any existing *cmd* with the same name. This should be used sparingly.

As a first example consider the following declaration, which shows a way to define a `\chapter` command that would essentially behave like the current `\TeX` command (except that it would accept an optional argument even when a `*` is parsed):

```
\NewDocumentCommand\chapter{s o m}
  {\IfBooleanTF{#1}{\typesetstarchapter{#3}}%
   {\typesetnormalchapter{#2}{#3}}}
```

The `\typesetnormalchapter` could test its first argument for being `-NoValue-` to see if an optional argument was present and act accordingly. See page 639 for details on `\IfBooleanTF` and testing for `-NoValue-`.

```
\NewCommandCopy{new-cmd}{original-cmd}
\NewEnvironmentCopy{new-env}{original-env}
```

If you want to make an existing command available under a new name (and reuse the original name for something else), then in the past you had to resort to low-level `\TeX` programming using `\let`. However, this does not work for commands with optional arguments or those defined with `\DeclareRobustCommand`, because they really consist of two commands, one of them with an internal name that is difficult to copy. To make this possible in a reliable way, `\NewCommandCopy` is provided. It analyzes the *original-cmd* and provides a copy of it that remains usable even after the original is redefined. Example A-4-3 on page 676 shows its usage.

There also exist `\RenewCommandCopy` and `\DeclareCommandCopy` but not `\ProvideCommandCopy`. For environments you can use `\NewEnvironmentCopy`, `\RenewEnvironmentCopy`, and `\DeclareEnvironmentCopy` in a similar fashion.

Fully expandable
document
commands

Document commands created using `\NewDocumentCommand`, etc., are set up in a way that they do not expand unexpectedly; i.e., they are robust in L^AT_EX's terminology but use a different mechanism (provided by modern engines) that makes them work even in places where `\DeclareRobustCommand` or `\MakeRobust` would fail. Making the commands robust so that they do not expand except when doing typesetting allows for a very efficient implementation besides the fact that some constructions simply fail in an expansion context.

There are, however, *very rare* occasions when it may be useful to create functions that always expand when used. This requires a much less efficient parser that imposes a number of restrictions on the nature of the arguments accepted by a function and the code it implements.¹ For this reason, the facility should be used only when *absolutely necessary* and is typically needed only in package or class files.

```
\NewExpandableDocumentCommand{cmd}{arg spec}{code}
```

This command is used to create a document-level *cmd* that grabs its arguments in a fully expandable manner. The argument specification for the function is given by *arg spec*, and the function executes the *code*. In general, the *code* also needs to be fully expandable, although there are cases where this is not necessary (e.g., in the example below). As usual, the `\Renew...`, `\Provide...`, and `\Declare...` variants are also available.

As an example in which at least a partially expandable command is needed, consider “hiding” `\multicolumn` inside a definition in order to preset the font and to center the column title. To allow for headers spanning several columns, we use an optional argument to keep the column number variable, e.g.,

```
\NewDocumentCommand\header{0{1}m}{\multicolumn{#1}{c}{\bfseries #2}}
```

That definition (or the same done with `\DeclareRobustCommand[2][1]{...}`) would fail, because the `tabular` code is scanning ahead to find a `\multicolumn` at the start of a cell, and with the command being robust, it cannot look into it.

2-cols	1-col	
—	—	<code>\NewExpandableDocumentCommand\header{0{1}m}</code>
		<code>{\multicolumn{#1}{c}{\bfseries #2}}</code>
		<code>\begin{tabular}{l l l}</code>
		<code>\header[2]{2-cols} & \header{1-col} \\\</code>
		<code>-- & --- & \\\ '! & '? & f ff fi ffi fl ffl</code>
<code>'! '?</code>	<code>f ff fi ffi fl ffl</code>	<code>\end{tabular}</code>

A-1-11

Parsing arguments by pure expansion imposes a number of restrictions on both the type of arguments that can be read and the error checking available:

- The “verbatim” argument type *v* is not available.
- The last argument (if any are present) must be one of the remaining mandatory types *m*, *r*, or *R*.

¹During expansions you cannot make assignments, and that means state information needs a lot of technical juggling, which makes the processing slow and restricts the types you can parse for.

- Argument processors (using >) are not available.
- It is impossible to differentiate between, for example, `\foo[` and `\foo{[}`: in both cases the `[` is interpreted as the start of an optional argument. This makes checking for arguments less robust than in the standard version.

All that plus the fact that it is much slower in processing is why the expandable commands should be avoided unless they are really needed.

```
\NewDocumentEnvironment{env}{arg spec}{begin code}{end code}
\RenewDocumentEnvironment{env}{arg spec}{begin code}{end code}
\ProvideDocumentEnvironment{env}{arg spec}{begin code}{end code}
\DeclareDocumentEnvironment{env}{arg spec}{begin code}{end code}
```

These declarations work in the same way as `\NewDocumentCommand`, etc., but create environments (`\begin{env} ... \end{env}`). In the document all arguments are given following `\begin{env}`.

In contrast to environments declared with `\newenvironment`, both the *begin code* and *end code* may access the arguments as defined by *arg spec*. Below is a reimplementaion of Example A-1-9 from page 630 making use of this feature and thereby getting much simpler. This time we also set `\finalhyphendemerits` to zero to prove that this makes the last citation use only two lines.

```
\newcounter{Citctr}
\NewDocumentEnvironment{Citation}{m}
{
  \stepcounter{Citctr}\begin{description}\item[Citation \arabic{Citctr}]
  {\hspace*{\fill}\nolinebreak[1]\quad\hspace*{\fill}\finalhyphendemerits=0
  \emph{#1}\end{description}}
}
```

Citation 1	Man is the measure of all things. <i>Protagoras</i>	\begin{Citation}{Protagoras} Man is the measure of all things. \end{Citation}
Citation 2	On mourra seul. <i>Blaise Pascal</i>	\begin{Citation}{Blaise Pascal} On mourra seul. \end{Citation}
Citation 3	Necessity is the plea for every infringe- ment of human freedom. <i>William Pitt</i>	\begin{Citation}{William Pitt} Necessity is the plea for every infringement of human freedom. \end{Citation}

A-1-12

Details on optional arguments

In contrast to commands created using L^AT_EX's `\newcommand`, optional arguments created using `\NewDocumentCommand` and friends may safely be nested. Thus, for example, following

```
\NewDocumentCommand\foo{0{something else}m}{I grabbed ‘#1’ and ‘#2’}
\NewDocumentCommand\baz{0{things}}{#1-#1}
```

using the command as `\foo[\baz[stuff]]{more stuff}` prints

I grabbed ‘stuff-stuff’ and ‘more stuff’

This is particularly useful when placing a command with an optional argument *inside* the optional argument of a second command. Note, however, that all commands involved are defined using `\NewDocumentCommand` and not one of the older methods; e.g., at the moment, it would not work with `\item` or many other kernel commands, though over time this will probably change.

When an optional argument is followed by a mandatory argument using the same delimiter (not a good syntax choice but possible), the parser issues a warning because not all optional arguments in front of the mandatory one could be omitted by the user, thus becoming in effect mandatory. There are possible use cases, though, for example, “`d()sr()`”. This would not allow for a single group of parentheses, but it would accept arguments of the form `(. .)(. .)`, `*(. .)`, or `(. .)*(. .)`. Whether or not that is a good syntax is a different question.

The defaults for O, D, and E arguments can use the result of grabbing another argument, even of one that comes later in the input. Thus, for example

```
\NewDocumentCommand\foo{O{#2} m}
```

would use the mandatory argument as the default for the leading optional one.

Spaces
before optional
arguments

T_EX finds the first argument after a multiletter command name irrespective of any intervening spaces. This is true for both mandatory and optional arguments, and there is no way to prevent this. Thus, `\foo[arg]` and `\foo␣[arg]` are equivalent.¹

Spaces are also ignored when collecting arguments up to the last mandatory argument to be collected (because it must exist). After

```
\NewDocumentCommand\foo{m o m}{ ... }
```

the user input `\foo{arg1}[arg2]{arg3}` and `\foo␣{arg1}␣␣␣[arg2]␣␣{arg3}` are both parsed in the same way.

However, the behavior of trailing optional arguments *after* any mandatory arguments is selectable. The standard settings allow spaces here, and thus with

```
\NewDocumentCommand\foobar{m o}{ ... }
```

both `\foobar{arg1}[arg2]` and `\foobar{arg1}␣[arg2]` find an optional argument. This can be changed by using the modifier `!` in the argument specification:

```
\NewDocumentCommand\foobar{m !o}{ ... }
```

where `\foobar{arg1}␣[arg2]` does not find an optional argument but treats `␣[arg2]` as ordinary input.

As mentioned before, there is a subtle difference in T_EX’s handling of control symbols where the command name is made up from a single symbol such as `\\`. Spaces are not ignored by T_EX here, and thus it is possible to require an optional argument to directly follow such a command without any intervening space. The most

¹In fact, even a line break is skipped over at this point, with sometimes surprising effects.

common example is the use of `\` in `amsmath` environments, which in the terms here would be defined as

```
\NewDocumentCommand\{\!s !o}{ ... }
```

Testing for optional argument values or optional tokens

All the tests in this section are expandable, so executing the tests is possible in situations where robust commands would simply stay put without expanding, e.g., inside moving arguments or `\typeout`, etc.

Optional arguments make use of dedicated variables to return information about the nature of the argument received. Those that test for the existence of a single token, i.e., `s`-type or `t`-type, return a special Boolean value that can be tested. All others that expect a value in the source (delimited in some way) return that value if found. If the optional argument is not present, they return a default value as defined in the specification of `O`, `D`, or `E` types, or they return the special value `-NoValue-` in the case of `o`, `d`, or `e` types.

This `-NoValue-` value is truly special: it prints if typeset, but it is defined with special `\catcode` settings so you cannot manually enter it in your document. Thus, if you type `\foo[-NoValue-]`, that is distinguishable from `\foo` without any optional argument. To test for this special value the code can make use of one of the following three tests, which differ only in the branches they support:

```
\IfNoValueTF{arg}{true code}{false code}
\IfNoValueT{arg}{true code}
\IfNoValueF{arg}{false code}
```

The `\IfNoValue...` tests are used to check if `<arg>` (`#1`, `#2`, etc.) is the special `-NoValue-` marker. For example

```
\NewDocumentCommand\foo{o m}
  {\IfNoValueTF {#1}%
    {\DoSomethingWithJustTheMandatoryArgument{#2}}%
    {\DoSomethingWithBothArguments{#1}{#2}}}
```

uses a different internal function if the optional argument is given than if it is not present. If you only need to do something if the argument is present (or not present), use one of the other two tests.

```
\IfValueTF{arg}{true code}{false code}
\IfValueT{arg}{true code}
\IfValueF{arg}{false code}
```

The reverse form of the `\IfNoValue...` tests are also available. The context determines which logical form makes the most sense for a given code scenario.

```
\IfBlankTF{arg}{true code}{false code}
\IfBlankT{arg}{true code}                \IfBlankF{arg}{false code}
```

The `\IfNoValueTF` command chooses the *true code* if the optional argument has not been used at all (and it returns the special `-NoValue-` marker), but not if it has been given an empty value. In contrast, `\IfBlankTF` returns true if its argument either is truly empty or contains only one or more normal blanks. Combining both gives full flexibility. As usual, the variants `\IfBlankT` and `\IfBlankF` are also provided for use when only one branch leads to some action.

	<code>\NewDocumentCommand\foo{m!o}{\par #1:</code>	
1: Real content in argument!	<code>\IfNoValueTF{#2}{No optional}%</code>	
2: Blanks in or empty argument!	<code>{\IfBlankTF{#2}{Blanks in or empty}%</code>	
3: Blanks in or empty argument!	<code>{Real content in}}%</code>	
4: Real content in argument!	<code>\space argument!}</code>	
5: No optional argument! [x]	<code>\foo{1}[bar] \foo{2}[] \foo{3}[] \foo{4}[\space] \foo{5} [x]</code>	A-1-13

Note that the `\space` in (4) is considered real content — because it is a command and not a “space” character — even though it results in producing a space. You can also observe in (5) the effect of the `!` specifier, preventing the last `\foo` from interpreting `[x]` as its optional argument.

```
\IfBooleanTF{arg}{true code}{false code}
\IfBooleanT{arg}{true code}                \IfBooleanF{arg}{false code}
```

To test if a star (s-type) or some other token (t-type) is present in the input, the above three tests are available: they test if *(arg)* (*#1*, *#2*, etc.) is “true” or “false”. This makes it easy to define conditional processing based on the existence of a star or some other token as show below:

```
\NewDocumentCommand\foo{sm}
{\IfBooleanTF{#1}{\DoSomethingWithStar{#2}}%
{\DoSomethingWithoutStar{#2}}}
```

Note that the `\IfBoolean...` tests cannot be used to test legacy T_EX or L^AT_EX switches; they are available only for testing the argument parsing results. They expect to receive either `\BooleanTrue` or `\BooleanFalse` as their argument, and these flags are set when searching for an optional character (using *s* or *t(char)*). The flags have user-accessible names so that you can easily define further commands whose results can be tested with `\IfBooleanTF`.

Using Embellishments

The optional embellishments offered through the *e* or *E*-type differ in two respects from other optional arguments: they are identified by a start token, but their value is then given in a following brace group and not by everything up to some end token. The other important difference is that the list of start tokens can appear in any order in the document and is still recognized.

To give an example, consider defining a command `\xgets` that produces a left arrow but allows you to add some material above and below. A possible syntax for this could be `\xgets^{above}`, `\xgets_{below}` and for material above and below `\xgets^{above}_{below}` (or the other way around). This is the sort of syntax that the e-types offer.

The `amsmath` package already has a `\xleftarrow` command that provides the functionality we want for `\xgets`, but it uses an optional and a mandatory argument for it, so you always have to specify the *above* argument even if it is empty. To exhibit the embellishment syntax, we define `\xgets` to simply pass its arguments to the `amsmath` command. We use the E-type and set up empty defaults so that if one or both of the embellishments are not present in the document, we pass empty values to the arguments of `\xleftarrow`. The order of tokens in the argument to E defines what is received as #1 (the value from `_`) and what as #2 (the value from `^`) regardless of the order used in the document, where we specified `^` first. For comparison, the example shows both the embellishment syntax and the one used by `amsmath`.

A-1-14	$\leftarrow \overset{x}{\leftarrow} \underset{y}{\leftarrow} \overset{x+y}{x-y}$	<pre>\usepackage{amsmath} \NewDocumentCommand\xgets{ E_{_}^{}}{\xleftarrow[#1]{#2}} \[\xgets \xgets^x \xgets_y \xgets^{x+y}_{x-y} \] \[\xleftarrow{} \xleftarrow{x} \xleftarrow[y]{} \xleftarrow[x-y]{x+y} \]</pre>
	$\leftarrow \overset{x}{\leftarrow} \underset{y}{\leftarrow} \overset{x+y}{x-y}$	

The E-type used in the above example defines one (empty) default value per test token. However, it is allowed to make the list of default values *shorter* than the list of test tokens. For those tokens that have no default, the special `-NoValue-` marker is returned (as for the e-type). Thus, for example

`E{!?}{\Bang}`

has default `Bang` for the `!` test character, but returns the `-NoValue-` marker as a default for `?`, which could then be tested for with one of the test commands. This allows mixing of explicit defaults with testing for missing values.

Using the body of an environment as an argument

While environments `\begin{env} ... \end{env}` are typically used in cases where the code implementing the `(env)`ironment does not need to access the contents of the environment (its “body”), it is sometimes useful to have the body as a standard argument.

This is achieved by *ending* the argument specification with `b`, which is a dedicated argument type for this situation. For instance, the next example grabs the body as argument #2 and doubles it with different font settings. Environments that use this feature can be nested.

A-1-15	Hello world:	
	Lighten up! <i>Hello world:</i>	<pre>\NewDocumentEnvironment{twice}{0{\ttfamily} +b}{#2#1#2?}{*}</pre>
	<i>Lighten up!</i> ?	<pre>\begin{twice}[\itshape] Hello world: \par Lighten up! \end{twice}</pre>
	TT?*wicewice?*	<pre>\par \begin{twice} T \end{twice}\begin{twice} wice \end{twice}</pre>

Special meaning
of ! together with b

The + prefix is used to allow multiple paragraphs in the environment's body. By default, spaces are trimmed at both ends of the body: in the example there would otherwise be spaces coming from the ends of the lines after `[\itshape]` and `up!`. Putting the prefix ! before `b` suppresses space-trimming. Argument processors discussed below can also be applied to the `b` specifier.

When `b` is used in the argument specification, the last argument of the environment declaration (e.g., `\NewDocumentEnvironment`), which consists of the *end code* to insert at `\end{env}`, is not really needed, because one can simply put that code at the end of the *start code*. Nevertheless, this *end code* argument must be provided, even if usually empty — here we added a ? and * in these places to show that they end up one after the other.

Using argument processors

Preprocessing arguments with “argument processors” is a somewhat more advanced topic, but it offers even more flexibility for setting up new document commands. You can, for example, define commands whose arguments (mandatory or optional) consist of comma-separated lists, and the splitting of such arguments is then automatically taken care of for you.

Argument processors are applied to an argument *after* it has been grabbed by the underlying system, but *before* it is passed to *code*. An argument processor can therefore be used to regularize input at an early stage, allowing the internal functions to be completely independent of the input format used in the document. Processors are applied to user input and to default values for optional arguments, but *not* to the special `-NoValue-` marker.

Each argument processor is specified by the syntax `>\{processor}` in the argument specification. Processors are applied from right to left, so that

```
>\ProcessorB >\ProcessorA m
```

would apply `\ProcessorA` followed by `\ProcessorB` to the tokens grabbed by the `m` argument. There are a number of predefined processors that we discuss below, but it is also possible to implement additional ones if the need arises. Because the latter is a rather specialized topic, we refer you to [116] for details.

`\SplitArgument{number}{token(s)}`

This processor splits the argument given at each occurrence of the *token(s)* up to a maximum *number* (thus dividing the input into a maximum of *number* + 1 parts). An error is given if too many *token(s)* are present in the input. The processed input is placed inside *number* + 1 sets of braces for further use, if necessary filled up by adding `{-NoValue-}` if there are fewer than *number* of *token(s)* in the argument. Spaces are trimmed at each end of each item parsed.

In the following example the command has one argument, which is supposed to contain two or fewer semicolons; i.e., it consists of a maximum of three parts. The

result after the split is then passed for further processing to an internal command with three normal mandatory arguments:

```
\NewDocumentCommand\foo{>{\SplitArgument{2}{;}} m}
  {\InternalFunctionWithThreeArguments#1}
```

Note that even though `\InternalFunctionWithThreeArguments` expects three arguments, we have to write `#1` without surrounding braces! The reason is that `#1` contains three brace groups after the processor has acted, i.e., exactly the syntax that the command expects.

`\SplitList{token(s)}`

This processor splits the argument given at each occurrence of the *token(s)* where the number of items is not fixed. Each item with spaces at each end trimmed is then wrapped in braces within `#1`. This result can then be further processed using a mapping function of some sort. For example:

```
\NewDocumentCommand\foo{>{\SplitList{;}} m}
  {\MappingFunction#1\MappingFunctionEnd}
```

The `\MappingFunction` would then need to be a command with one mandatory argument that picks up one brace group from `#1`, checks if it has reached the end of the list (where it finds `\MappingFunctionEnd` instead of a brace group), and if not processes its argument and then calls itself again to pick up the next. The L3 programming layer offers a large selection of mapping functions that work in a similar way, but it is not too difficult to write them in traditional TeX either. However, even simpler is to make use of `\ProcessList` that is offered for exactly this scenario.

`\ProcessList{list}{function}`

The command `\ProcessList` applies a *function* to every entry in a *list*. The *function* should absorb one argument: the list entry. For example

```
\NewDocumentCommand\foo{>{\SplitList{;}}m}{\ProcessList{#1}{\typeout}}
```

would display each part of `\foo's` argument on the terminal.

Two further argument processors are predefined: the first can be quite useful when dealing with arbitrary user input, while the second provides only some syntactic sugar and is mainly there because it was trivial to define it.

`\TrimSpaces \ReverseBoolean`

The `\TrimSpaces` processor removes any leading and trailing spaces (tokens with character code 32 and category code 10) from either end of the argument.

In the following example we define a normal command that retains spaces and a `\spaceless` version that trims them off to show the difference:

	<code>\NewDocumentCommand\withspace{m}{\textbf{#1}}</code>	
	<code>\NewDocumentCommand\spaceless{>{\TrimSpaces}m}{\textbf{#1}}</code>	
Test Hello world lighten up!	Test <code>\withspace{ Hello world }</code> lighten up!	<code>\par</code>
Test Hello world lighten up!	Test <code>\spaceless{ Hello world }</code> lighten up!	

A-1-16

While the user error here is obvious and probably never happens, there are many occasions where it is not and people split arguments over several lines to improve readability (and thereby introduce unwanted spaces). In such cases, trimming the argument value helps avoid subtle errors. `\TrimSpaces` removes even multiple spaces in a row if they happen to end up at the start or end of the argument.

Finally, the `\ReverseBoolean` processor reverses the logic of outcome of an s-type or t-type argument so that the example from earlier would become

```
\NewDocumentCommand\foo{>{\ReverseBoolean}s m}
  {\IfBooleanTF{#1}{\DoSomethingWithoutStar{#2}}}%
  {\DoSomethingWithStar{#2}}}
```

in other words a somewhat convoluted way of implementing `\IfNotBooleanTF`, which does not exist in the language.

A.1.5 Changing arguments to command names

There are a few cases when using commands or declaring new commands in which it is impossible to provide the command name as a single `\. . .` token — instead the command has to be “constructed”. To facilitate this task, the L3 programming layer offers a general mechanism to manipulate arguments in various ways, but for common cases there are also two CamelCase commands for use with `\NewDocumentCommand` and similar constructs.

<code>\UseName{string}</code>	<code>\ExpandArgs{spec} <cmd> {arg₁} ... {arg_n}</code>
-------------------------------	--

`\UseName` turns the *string* into a command name and then immediately executes it. The `\ExpandArgs` alters the arguments of *cmd* according to a *spec*. The *spec* consists of a list of letters, each of which denotes what should happen to the corresponding argument: *c* stands for an argument that is turned into a ‘c’ommand; an *n* represents a ‘n’ormal argument that is not altered, and *N* stands for a ‘N’ormal argument, which is also left unchanged but one consisting only of a single token (and usually unbraced).

For example, *cc* stands for “turn the first two arguments into commands before passing them to *cmd*”. This could then be used together with `\NewCommandCopy` as the *cmd* as follows

```
\NewDocumentCommand\savebyname{m}
  {\ExpandArgs{cc}\NewCommandCopy{saved#1}{#1}}
```

after which a declaration such as `\savebyname{LaTeX}` would copy the definition of `\LaTeX` to `\savedLaTeX`.

As a more complex example, consider the case of this book where we wanted to have a number of “copyedit” commands to add notes into the margin or for longer notes in the main galley (using the `todonotes` package). The copyeditors should have their notes in their own color and numbered sequentially.

For this we define¹ the command `\newcopyedit`, which expects as its mandatory argument the initials of the copyeditor (e.g., `fmi`) and as an optional argument a color name (line 1). Using the initials we define a counter (line 2), e.g., `todofmi`, to count the notes for that person, and we define a command to make the notes, e.g., `\fmi`. To be able to use `\NewDocumentCommand` we need to turn `#2` into a command name, which is done with the help of `\ExpandArgs{c}` (line 3). This newly defined command scans for an optional star and one mandatory argument. It increments the counter associated with the initials (line 4) and then tests for the optional star (line 5). If there was one, it uses `\todo` to make an inline note (line 6) and otherwise a marginal note (line 7). In either case it shows the initials (`#2`) followed by the counter representation, which again needs to be constructed this time with the help of `\UseName` (lines 6 and 7). Finally (line 8), we apply the definition twice to get the copyedit commands `\fmi` and `\ufi`, which we then use within the text.

```
\usepackage{kantlipsum,todonotes}
\NewDocumentCommand\newcopyedit{0{blue} m}           % 1.1
  {\newcounter{todo#2}%                               % 1.2
   \ExpandArgs{c}\NewDocumentCommand{#2}{s m}%       % 1.3
   {\stepcounter{todo#2}%                             % 1.4
    \IfBooleanTF {##1}%                               % 1.5
      {\todo[inline,color=#1!20]{#2 \UseName{thetodo#2}: ##2}}% % 1.6
      {\todo[color=#1!20]{#2 \UseName{thetodo#2}: ##2}}}% % 1.7
   \newcopyedit{fmi} \newcopyedit[red]{ufi}          % 1.8
Kant:\fmi{correct} \kant*[1][1]\fmi{use a different phrase}
\kant[1][2]\ufi*{Add another paragraph!}
```

fmi 1: correct

fmi 2: use a
different phrase

Kant: As any dedicated reader can clearly see, the Ideal of practical reason is a representation of, as far as I know, the things in themselves; as I have shown elsewhere, the phenomena should only be used as a canon for our understanding. The paralogsms of practical reason are what first give rise to the architectonic of practical reason.

ufi 1: Add another paragraph!

A-1-17

There are several other single letters supported in the L3 programming layer that could be used in the *spec* to manipulate arguments in other ways. If you are interested, take a look at the “Argument expansion” section in the L3 programming layer documentation [115].

¹The actual definition we used in the book also added a bookmark to make navigation easy (as explained in Section 2.4.6 on page 103), but that is not shown here.

A.2 Counters and length expressions

A.2.1 Defining and changing counters

Every number internally generated by L^AT_EX has a *counter* (register) associated with it. The name of the counter is usually identical to the name of the environment or the command that generates the number except that it does not start with a `\`. The following is the list of all counters used in L^AT_EX's standard document classes:

<code>part</code>	<code>enumi</code>	<code>figure</code>	<code>equation</code>
<code>chapter</code>	<code>enumii</code>	<code>table</code>	<code>page</code>
<code>section</code>	<code>enumiii</code>	<code>footnote</code>	<code>totalpages</code>
<code>subsection</code>	<code>enumiv</code>	<code>mpfootnote</code>	
<code>subsubsection</code>			
<code>paragraph</code>			
<code>subparagraph</code>			

In addition, there are several configuration parameters that also use the counter interface for modifications. However, they normally do not change when a document is processed. These are:

<code>totalnumber</code>	<code>bottomnumber</code>	<code>secnumdepth</code>	<code>errorcontextlines</code>
<code>topnumber</code>	<code>dbltopnumber</code>	<code>tocdepth</code>	

An environment declared by `\newtheorem` can also have a counter with the same name associated with it, unless the optional argument indicates that it is to be numbered together with another environment. And, of course, additional counters may get added by packages; e.g., the `float` package declares one counter per float type in order to number the floats of this type.

The value of a counter is a single integer. Several counters can be combined into a number, as is usually the case for numbering section headings. For example, in the `book` or `report` classes, 7.4.5 identifies the fifth subsection of the fourth section in the seventh chapter.

Below we describe all the basic L^AT_EX commands that define counters and modify or display their values. These commands are much more powerful if used in conjunction with the `calc` package, which is discussed in Section A.5.2.

`\newcounter{ctr}[parent-ctr]`

This command globally defines a new counter, *ctr*, and initializes it to zero. If a counter with the name *ctr* is already defined, an error message is printed. When you specify the name of another counter as the optional argument, *parent-ctr*, then the newly defined *ctr* is reset when the counter *parent-ctr* is incremented with the `\stepcounter` or `\refstepcounter` command. It also defines the command `\the<ctr>` to always expand to `\arabic{ctr}` even if the optional argument is given — compare this to the behavior of the `\counterwithin` command described next.

```
\counterwithin*[format-cmd]{ctr}{parent-ctr}
```

The operation that defines that one counter is reset whenever another counter is stepped is also available as the command `\counterwithin`. In contrast to `\newcounter`, it alters `\the<ctr>` to typeset `\the<parent-ctr>.<format-cmd>{ctr}` where `<format-cmd>` is a command such as `\roman`. If the optional argument is not present, it defaults to `\arabic`.

If you use the starred form, then `\the<ctr>` is not touched, which is useful if it needs a more complex definition or is already correctly set up. Obviously, in that case the optional argument is meaningless and is ignored if given.

```
\counterwithout*[format-cmd]{ctr}{parent-ctr}
```

However, sometimes you need the opposite action. For example, the `report` class defines the `footnote` counter to be reset whenever a new chapter starts. If you want your footnotes nevertheless to be numbered sequentially throughout a document, then specifying

```
\counterwithout{footnote}{chapter}
```

achieves this for you by removing it from the reset list of the `chapter` counter and altering `\thefootnote` accordingly. If you use the optional `<format-cmd>`, then this gets applied in the definition of `\the<ctr>`; otherwise, `\arabic` is used. As above, the starred form does not alter `\the<ctr>` at all.

```
\setcounter{ctr}{val}      \addtocounter{ctr}{val}
```

With `\setcounter` the value of counter `ctr` is globally set equal to the value `val`. With `\addtocounter` it is globally incremented by `val`.

```
\stepcounter{ctr}      \refstepcounter{ctr}
```

Both commands globally increment the counter `ctr` and reset all subsidiary counters — that is, those declared with `<ctr>` in the optional argument on the `\newcounter` command or in the second argument of `\counterwithin`.

The `\refstepcounter` command additionally defines the current `\ref` value to be the text generated by the command `\the<ctr>`. Note that whereas stepping a counter is a global operation, setting the current `\ref` value is done locally and thus is valid only inside the current group. As a result, Example A-2-1 on the next page does not produce the desired output but instead picks up the section number. The correct solution would be to move `\refstepcounter` before the `\textbf` command — and also precede it with `\leavevmode` so that it is not executed in vertical mode, which makes a difference if `hyperref` is used.¹

¹The `hyperref` package adds an anchor at the point `\refstepcounter` is used, and that can alter the spacing in the document if it is encountered in vertical mode.

5 A Failure

Exercise 5.a: A test.

Exercise 5.b: Another test.

Referencing exercises: 5 and 5.

```
\newcounter{ex} \renewcommand\thesection{\thesection.\alph{ex}}
\newenvironment{EX}{\begin{flushleft}%
  \textbf{\refstepcounter{ex}Exercise-\thesection:}}
  {\end{flushleft}}
\setcounter{section}{4} % for testing
\section{A Failure}
\begin{EX} \label{A} A test. \end{EX}
\begin{EX} \label{B} Another test. \end{EX}
Referencing exercises: \ref{A} and \ref{B}.
```

A-2-1

<code>\value{ctr}</code>	<code>\arabic{ctr}</code>	<code>\roman{ctr}</code>	<code>\Roman{ctr}</code>
	<code>\alph{ctr}</code>	<code>\Alph{ctr}</code>	<code>\fnsymbol{ctr}</code>

The `\value` command produces the current value of a counter to be used in places where L^AT_EX expects to see a number, such as in the *val* argument of the `\setcounter` or `\addtocounter` command or when comparing numbers using the command `\ifthenelse` from the `ifthen` package.

However, despite its name, the `\value` command cannot be used to typeset the value of the counter! For that purpose, a set of presentation commands are available, all of which take a counter name as an argument.

Counter presentations
with restricted ranges

With `\arabic` the counter value is represented as an Arabic numeral. With `\roman` and `\Roman`, lowercase and uppercase roman numerals are produced, respectively. The remaining commands can be used only if the counter value is within a certain range. The `\alph` command displays the value as a lowercase letter: a, b, c, ..., z. Thus, the value should lie in the range 1, ..., 26; otherwise, an error is signaled. The `\Alph` command is similar but produces uppercase letters. Finally, `\fnsymbol` represents the counter value as a traditional footnote symbol (e.g., *, †). In that case the value must not be greater than 9, unless an extension package, like `footmisc` or `fntcount`, is used. The next example shows all of these commands in action.

8, viii, VIII, h, H, ††
Anno Domini MCMXCIV

```
\newcounter{exa}\setcounter{exa}{8}
\arabic{exa}, \roman{exa}, \Roman{exa}, \alph{exa},
\Alph{exa}, \fnsymbol{exa} \par
\setcounter{exa}{1994} Anno Domini \scshape{\roman{exa}}
```

A-2-2

`\the<ctr>`

A shorthand to produce the default visual representation for a counter *ctr* is provided by the command `\the<ctr>` (e.g., `\thesection` for the `section` counter).

As mentioned earlier, this command is initialized by the `\newcounter` declaration to produce `\arabic{ctr}`. However, in L^AT_EX such a visual representation often involves more than a single number. For example, with sectioning counters one usually displays the value of the current section as well as the value of the current subsection, and so on. For this reason `\the<ctr>` is typically (re)defined to produce a more complex representation. This practice becomes even more important when you consider

that `\refstepcounter` not only increments a certain counter and resets lower-level counters but also defines the “current” label (as picked up by `\label`) to be the result of `\the<ctr>` for the counter being stepped.

As an example, inside the standard article class, we find definitions for sectioning counters equivalent to the following:

```
\newcounter{part}                \newcounter{section}
\newcounter{subsection}[section] \newcounter{subsubsection}[subsection]

\renewcommand\thepart            {\Roman{part}}
\renewcommand\thesection        {\arabic{section}}
\renewcommand\thesubsection     {\thesection.\arabic{subsection}}
\renewcommand\thesubsubsection{\thesubsection.\arabic{subsubsection}}
```

You see how lower-level counters are reset when upper-level counters are stepped, as well as how the representation of the counters (the `\the...` commands) are constructed from the current counter and the counters at a higher level. Note how the `part` counter does not influence any of the lower levels.

As another example, we look at Table 4.2 on page 256, which shows the structure of the enumeration list counters. In fact, these counters are defined inside the file `latex.ltx`, which contains the kernel code for \LaTeX . Only the representation, prefix, and label field commands are defined in the standard class files as follows:

```
\renewcommand\theenumi  {\arabic{enumi}}
\renewcommand\theenumii {\alph{enumii}}  \renewcommand\p@enumii {\theenumi}
\renewcommand\theenumiii {\roman{enumiii}} \renewcommand\p@enumiv {\p@enumiii\theenumiii}
\renewcommand\theenumiv {\Alph{enumiv}}   \renewcommand\p@enumiii {\theenumi(\theenumii)}

\newcommand\labelenumi  {\theenumi.}      \newcommand\labelenumii {\(\theenumii)}
\newcommand\labelenumiii {\theenumiii.}   \newcommand\labelenumiv {\theenumiv.}
```

Finally, we show how the standard classes handle the equation counter. Like the enumeration counters, this counter is declared inside `latex.ltx`. In the article class, the counter is never reset:

```
\renewcommand\theequation{\arabic{equation}}
```

In the report and book classes, the equation number is reset for each chapter with the `\counterwithin` command:

```
\counterwithin{equation}{chapter}
% This automatically does:
%   \renewcommand\theequation{\thechapter.\arabic{equation}}
```

Thus, the representation also differs in both cases.¹

¹The actual definition is somewhat more complex, because some low-level code is used to suppress the chapter number if it is zero.

A.2.2 fmtcount — Specially formatted counters and numbers

We already looked at the `fmtcount` package in Section 3.3.1 on page →I 154 and its ability to produce ordinal numbers from counter values, allowing you to generate “Second section in 1st appendix” in a number of languages. In addition, it offers a set of other counter presentations not available with standard L^AT_EX.

<code>\binary{ctr}</code>	<code>\octal{ctr}</code>	<code>\hexadecimal{ctr}</code>	<code>\Hexadecimal{ctr}</code>
<code>\aaalph{ctr}</code>	<code>\AAalph{ctr}</code>	<code>\abalph{ctr}</code>	<code>\ABalph{ctr}</code>

These work like `\arabic`, etc., but format the counter value of *ctr* in a special format. There is also a `\decimal` command, which by default produces exactly the same as L^AT_EX’s `\arabic` (but see below).

The different formats have some restrictions on the size of the value they accept, e.g., for `\octal`, only numbers below 32769 are allowed.¹

Commands that produce letters (in addition to, or instead of, digits) exist in two forms: if the command name starts with an uppercase letter, then uppercase letters are typeset; otherwise lowercase letters. The `\. . alph` commands extend the range of supported values by using several letters when we have exhausted “a, . . . , z”. The command `\aaalph` then continues with “aa, bb, . . . , zz, aaa, bbb, . . .”, while `\abalph` continues with “ab, ac, . . . , az, ba, bb, bc, . . .”.

<code>\padzeroes[<i>digits</i>]</code>
--

Sometimes you may need to typeset a set of numbers with always the same number of digits, if necessary padded with zeros. This is available for all commands that produce digits (and possible letters in addition). To specify the padding you use `\padzeroes` with the optional argument specifying the expected number of *digits* in the result (if the argument is not given, it defaults to 17). If the counter value is larger, then no zeros are added, and the value is typeset as is (with more digits); e.g., the binary value is not padded in the example below. To return to no padding, use 0 in the *digits* argument.

```

\usepackage{fmtcount} \newcounter{test} \setcounter{test}{29}
\padzeroes[4]
\decimal{test} \binary{test} \octal{test} \hexadecimal{test} \par
0029 11101 0035 001d Unpadded: \padzeroes[0]
Unpadded: 29 11101 35 1d \decimal{test} \binary{test} \octal{test} \hexadecimal{test}

```

A-2-3

<code>\decimalnum{num}</code>	<code>\binarynum{num}</code>	<code>\octalnum{num}</code>
<code>\hexadecimalnum{num}</code>	<code>\Hexadecimalnum{num}</code>	<code>\aaalphnum{num}</code>
<code>\AAalphnum{num}</code>	<code>\abalphnum{num}</code>	<code>\ABalphnum{num}</code>

Instead of formatting the value of a counter, you can format an explicit number by using one of these commands. They too react to `\padzeroes` as explained above.

¹There is a limit imposed by T_EX for counter values, but that is much higher; thus, this is a restriction of the implementation that may get lifted one day.

A.2.3 sillypage — Page and other counting à la Monty Python

Even in a serious book there should be time for some lighthearted jokes (once in a while at least), and if you have read carefully, you may have noticed one or the other within these pages.

During the last stages of producing this book, I came across the `sillypage` package (by Phelype Oleinik, Paulo Cereda, `samcarter`, and Ulrike Fischer) that brings a masterpiece of British sketch culture to the \LaTeX world: it provides Monty Python's "The Ministry of Silly Walks" in the form of a counter format, depicting the walk through twelve pictograms:

A-2-4

By specifying `\pagenumbering{silly}` the page numbers of your document loop through the above walk, while with `sillynumeral`, each page number is uniquely mapped to a composition of pictograms (in base 12). In either case it turns your document into a nice thumbnail book in which the page numbers perform the silly walk in a kineographic fashion. Be careful to avoid using `\pageref` when silly page numbering is in force, because this command would then display the references as (rather large) pictograms, which may not be what you intended.

There is also the command `\silly`, which requires a \LaTeX counter name as its argument and can be used like `\arabic` or `\roman`. Finally, the two commands `\sillystep` and `sillynumeral` expect an integer and turn it into the corresponding pictogram or sequence of pictograms, respectively.

A.2.4 Defining and changing space parameters

In \LaTeX two kinds of space parameters (lengths) exist: “rigid” lengths (called $\langle dimen \rangle$ in *The \TeX book* [84]), which are fixed, and “rubber” lengths (called $\langle skip \rangle$ in *The \TeX book*), which have a natural length and a degree of positive and negative elasticity. New lengths in \LaTeX are allocated as type $\langle skip \rangle$ so that you always have the choice of initializing them as rigid or rubber lengths (by specifying plus and minus parts). On the other hand, all standard lengths in \LaTeX are of type rigid, unless specifically declared in Appendix C of the *\LaTeX Manual* to be rubber. Here we discuss the commands provided by \LaTeX for dealing with lengths.

`\newlength{cmd}`

The declaration `\newlength` allocates a new (rubber) length register and associates the command name `cmd` with it. If a command `cmd` already exists, you get an error message. The new length is preset to zero. Just like with `\newcommand`, you find that the braces around `cmd` are often omitted in actual code because the argument must consist of a single command name.

<i>dimension</i>	<i>explanation</i>	<i>visualization</i>
sp	Scaled point (65536sp = 1 pt) T _E X's smallest unit	
pt	Point = $\frac{1}{72.27}$ in = 0.351 mm	
bp	Big point = $\frac{1}{72}$ in = 0.353 mm, also known as PostScript point	
dd	Didot point = $\frac{1}{72}$ of a French inch = 0.376 mm	
mm	Millimeter = 2.845pt	u
pc	Pica = 12pt = 4.218mm	└─┘
cc	Cicero = 12dd = 4.531 mm	└─┘
cm	Centimeter = 10mm = 2.371pc	└───┘
in	Inch = 25.4mm = 72.27pt = 6.022pc	└──────────┘
ex	Height of a small “x” in the current font (approximately)	┐
em	Width of capital “M” in current font (approximately)	└─┘
mu	Math unit (18mu = 1 em) for positioning in math mode	
fil	Infinite stretch or shrink, i.e., can be used only in plus or minus part of a rubber length and overwrites any finite stretch present	
fill	Second order infinite stretch or shrink, overwrites first order	
filll	Third order infinite stretch or shrink (for emergencies)	

Table A.1: L^AT_EX's units of length

```
\setlength{cmd}{length}    \addtolength{cmd}{length}
```

This sets the value of the length command *cmd* equal to the length *length* or, in the case of `\addtolength`, adds the specified amount to the existing value. In the examples below, the T_EX command `\the` is used to typeset the actual contents of the length variable. It requires the register command name *without* braces!

```

\newlength\Mylen
\setlength \Mylen{10mm} Mylen = \the\Mylen
\addtolength\Mylen{0pt plus 4pt minus 2pt}
\par Mylen = \the\Mylen
\addtolength\Mylen{-10mm plus 1fil}
\par Mylen = \the\Mylen

```

Mylen = 28.45274pt
Mylen = 28.45274pt plus 4.0pt minus 2.0pt
Mylen = 0.0pt plus 1.0fil minus 2.0pt

A-2-5

Lengths can be specified in various units, as shown in Table A.1. Notice the difference between the typographic point (pt), which is normally used in T_EX, and the (big) point used by PostScript and PDF, for example. Thus, when reserving space for an EPS picture, you need to specify the bounding box dimension in bp to get the correct space.

command	explanation
<code>\hspace{len}</code>	Horizontal space of width <i>len</i> that can be a rigid or a rubber length
<code>\enspace</code>	Horizontal space equal to half a quad
<code>\quad, \qquad</code>	Horizontal space equal to the em value of the font; <code>\qquad</code> equals two em
<code>\hfil</code>	Horizontal rubber space that can stretch between 0 and ∞
<code>\hfill</code>	Horizontal rubber space that can stretch between 0 and ∞ ; overwrites <code>\hfil</code>
<code>\hrulefill</code>	Similar to <code>\hfill</code> , but draws a solid horizontal line
<code>\dotfill</code>	Similar to <code>\hfill</code> , but draws a dotted line

Table A.2: Predefined horizontal spaces

<code>\settowidth{cmd}{text}</code>	
<code>\settoheight{cmd}{text}</code>	<code>\settodepth{cmd}{text}</code>

Instead of specifying a length value explicitly, three commands are available that allow you to measure a given text and assign the result. With `\settowidth` the value of the length command *cmd* is set equal to the natural width of the typeset version of *text*. This command is very useful for defining lengths that vary with the string contents or the type size. The other two commands work similarly but measure the height and the depth rather than the width of the typeset *text*.

	<code>\newlength\Mylen</code>
width = 47.67996pt	<code>\settowidth \Mylen{Typography} width = \the\Mylen \\\</code>
height = 6.76pt	<code>\settoheight\Mylen{Typography} height = \the\Mylen \\\</code>
depth = 2.18pt	<code>\settodepth \Mylen{Typography} depth = \the\Mylen \\\</code>
Use larger font and recalculate:	<code>Use larger font and recalculate: \\\</code>
A-2-6 width = 57.21597pt	<code>\settowidth\Mylen{\large Typography} width = \the\Mylen</code>

<code>\fill</code>	<code>\stretch{dec-num}</code>
--------------------	--------------------------------

These two rubber lengths are intended to be used in the argument of `\vspace` and similar commands. The `\fill` rubber length is preset with a natural length of zero but can stretch to any positive value; in other words, it holds the value `0pt` plus `1fill`. Do not change its value! It is used in various places in the kernel, and a change would produce strange effects.

An often more useful rubber length is provided by the `\stretch` command — in fact, `\fill` is equivalent to `\stretch{1}`. More generally, `\stretch{dec-num}` has a stretchability of *dec-num* times `\fill`. It can be used to fine-tune the positioning of text horizontally or vertically — for instance, to provide spaces that have a certain relation to each other. Example A-2-8 demonstrates its application.

Horizontal space

Table A.2 shows horizontal space commands known to \LaTeX . A flexible horizontal space of any desired width is produced by the `\hspace` command. The command

<i>command</i>	<i>explanation</i>
<code>\vspace{len}</code>	Vertical space of height <i>len</i> that can be a rigid or a rubber length
<code>\smallskip</code>	Vertical skip of <code>\smallskipamount</code> (default about one quarter of <code>\baselineskip</code>)
<code>\medskip</code>	Vertical skip of <code>\medskipamount</code> (default about one half of <code>\baselineskip</code>)
<code>\bigskip</code>	Vertical skip of <code>\bigskipamount</code> (default about one <code>\baselineskip</code>)
<code>\vfill</code>	Vertical rubber length that can stretch between 0 and ∞

Table A.3: Predefined vertical spaces

`\hspace*` is the same as `\hspace`, but the space is never removed — not even at a line boundary.

A space in front of or following an `\hspace` or `\hspace*` command is significant, as the following example shows:

This is a	0.5 in wide space.	<code>\par This is a\hspace{0.5in}0.5~in wide space.</code>	
This is a	0.5 in wide space.	<code>\par This is a \hspace{0.5in}0.5~in wide space.</code>	
This is a	0.5 in wide space.	<code>\par This is a \hspace{0.5in} 0.5~in wide space.</code>	A-2-7

The next example shows how rubber lengths can be used to fine-tune the positioning of information on a line. Note that the `\hfill` command is, in fact, an abbreviation for `\hspace{\fill}`. To save typing, we also defined a command with an optional argument, `\HS`, which behaves like `\hfill` when used without an argument but can be made less or more flexible than that command by specifying the stretchability (a value of 1 has the same effect as `\hfill`).

		<code>\newcommand{\HS}[1][1.]{\hspace{\stretch{#1}}}</code>	
		<code>\begin{center}</code>	
left		<code>left \hfill</code>	right\\
left	$\frac{2}{5}$	<code>left \HS[2]\fbox{\$\frac{2}{5}\$}\HS[5]</code>	right\\
left	middle	<code>left \HS middle \hfill</code>	right\\
left	middle	<code>left \hrulefill\ middle \hrulefill\</code>	right\\
left		<code>left \dotfill\</code>	right\\
left		<code>left \dotfill\ \HS[.5] \dotfill\</code>	right\\
left		<code>left \dotfill\ \HS \dotfill\</code>	right\\
left		<code>left \dotfill\ \HS[2.] \dotfill\</code>	right
		<code>\end{center}</code>	

A-2-8

Vertical space

A vertical space is produced with the `\vspace` command, which works similarly to `\hspace`. In particular, a `\vspace*` command generates vertical space that is never eliminated, even when it falls on a page break where a `\vspace` command would be ignored at this point. Table A.3 shows vertical space commands known to L^AT_EX that are common to all standard classes.

L^AT_EX users are often confused about the behavior of the `\vspace` command. When used inside a paragraph, the vertical space is added after the end of the line

containing the `\vspace`; between paragraphs it behaves as you would expect.

The use of a `\vspace` command inside a paragraph is perhaps a bit surprising.

The `\vspace{3mm}` use of a `\verb!\vspace!` command inside a paragraph is perhaps a bit surprising.

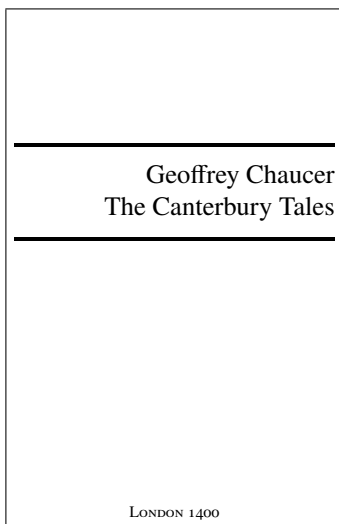

`\vspace{\baselineskip}`

Between paragraphs, adjusting the spacing is somewhat more useful, and it allows control of the white space before and after displayed material.

Between paragraphs, adjusting the spacing is somewhat more useful, and it allows control of the white space before and after displayed material.

A-2-9

Stretchable space as introduced on page 653 can also be used for vertical material. The `\vfill` command is, in fact, an abbreviation for a blank line followed by `\vspace{\fill}`. More generally, you can use the `\stretch` command in combination with `\vspace` to control the layout of a complete page. This could be useful for designing a title page: if the title should be placed one third of the way down the page, one simply has to place `\vspace*{\stretch{1}}` before it and `\vspace*{\stretch{2}}` after it.

```
\newcommand\HR{\noindent\rule{\linewidth}{1.5pt}}
\begin{titlepage}
  \vspace*{\stretch{1}}
  \HR
  \begin{flushright}
    \LARGE Geoffrey Chaucer \\\
    The Canterbury Tales
  \end{flushright}
  \HR
  \vspace*{\stretch{2}}
  \begin{center}
    \textsc{London 1400}
  \end{center}
\end{titlepage}
```

A-2-10

`\addvspace{space}`

While \LaTeX 's user command `\vspace` unconditionally adds a vertical space (which is removed only at page boundaries, while its starred form even suppresses this action), there exists another command for adding vertical space that is often used in the kernel and in some package files. The `\addvspace` command has somewhat different semantics, and although it appears to be a user-level command judging from its name, in fact it is not.

 *Use with care — if at all*

In contrast to `\vspace`, the command `\addvspace` is allowed only in vertical mode (i.e., between paragraphs). If used in horizontal mode, it issues the famous “Something’s wrong—perhaps a missing `\item`” error, which most L^AT_EX users know and love. Most of the time this error has nothing to do with a missing or misplaced `\item` but simply signals a misplaced `\addvspace` command. But it shows some of the history of this command: originally, it was developed and used solely for spacing items in list environments.

The other important semantic difference between `\vspace` and `\addvspace` is that the latter adds a space whose size depends on any directly preceding space. The precise rules are inherited from L^AT_EX 2.09 and show some strange discontinuities that nobody these days seems to be able to explain fully, though for backward compatibility the command is retained in this form. If s is the space to be added by `\addvspace` and ℓ is the size of the vertical space (if any) before the current point, then the following rules apply:

If	$s < 0\text{pt} < \ell$	do	backup by s
elseif	$\ell = 0\text{pt}$	do	add an additional space of s
		else	make a space of $\max(\ell, s)$ out of the two

If we ignore for the moment the special cases in the first two lines of the rules, then the idea behind `\addvspace` can be described as follows: if we have two vertically oriented constructs, such as a list and a heading, and both want to surround themselves with some vertical spacing before and after, it is probably not a good idea if both such spaces are applied if the objects directly follow each other. In that case using the maximum of both spaces is usually a better solution. This is why lists, headings, and other typeset elements use `\addvspace` rather than `\vspace`.

Surprising space
size changes 

This has some rather surprising effects. If you have two such display objects following each other, then only the maximum of the space surrounding them is used. However, if you try to enlarge that space slightly, such as by placing `\vspace{4pt}` between them, then suddenly the space becomes far larger. This result occurs because in a sequence like

```
\addvspace{10pt} \vspace{4pt} \addvspace{8pt}
```

the second `\addvspace` is unable to see the first and therefore adds all of its space (with the result that the total space is 22pt); without the `\vspace` in the middle you would get 10pt total. The `\vspace` does not interact with the following `\addvspace` because it actually generates a space of 4pt followed by a space of 0pt so that the second rule applies.

If you notice that your space got too large and you reduce your correction to, say, `\vspace{2pt}`, nothing changes substantially (you still get 20pt). Even more surprisingly, if you try to make the original space smaller by using, say, `\vspace{-3pt}`, you end up with 15pt total space — still more than before.

To actually get a space of 7pt in that place, you would need to back up by 11pt. Unfortunately, there is no way to determine the size of the necessary space other than

by experimenting or looking into the definitions of the objects above and below, to find out what `\addvspace` values are used at a given point.

The same problem arises if some other invisible object separates two consecutive `\addvspace` commands. For example, a color-changing command or a `\label` effectively hides a previous `\addvspace`, with the result that suddenly not the maximum, but the sum of both spaces, appears.

`\addpenalty{penalty}`

Although `\addpenalty` is not a spacing command, it is described here because it is intended to work together with `\addvspace`. A penalty is \TeX 's way of assigning a “badness” to breakpoints. A high penalty means that this is a bad place to break, while a negative penalty indicates to \TeX that this is a rather good place to start a new line or a new page. Details of this mechanism can be found in Chapters 14 and 15 of [84].

The `\addpenalty` command requires a \TeX penalty value as an argument (useful values are between -10000 and 10000). For example, `\@startsection` discussed in Chapter 2 uses `\addpenalty` to make the space before a heading become a good place to break (default value -300). If `\addpenalty` and `\addvspace` are mixed, then this has two effects:

- \TeX still uses the maximum of the spaces even if `\addpenalty` appears between two `\addvspace` commands.
- \TeX moves the potential break “visually” to the beginning of the white space, even if there is an `\addvspace` before the `\addpenalty`.

The second feature is important to avoid white space remaining at the bottom of pages. See page 771 for a discussion of how this is achieved.

A.2.5 The L3 programming layer — Computation support

In 2020 (more or less thirty years after its initial conception) the L3 programming layer has become an official part of the \LaTeX format and with it huge libraries for programming if you implement a package using that layer — its reference manual alone amounts to more than 300 pages [115]. These days many packages and the new parts of \LaTeX core are written using this layer, and more will follow over time.

Some parts of the layer are also very useful on the document level or in packages that are otherwise implemented in traditional $\LaTeX_{2\epsilon}$ style and are therefore offered also with interfaces that can be directly used in such scenarios. In this section we look at a few that deal with floating point, integer, and length calculations. Information beyond what is presented here can be found in the reference manual [115].

`\fpeval{floating point expression}`

The expandable command `\fpeval` takes as its argument a floating-point expression and produces a result using the normal rules of mathematics. As this command is expandable, it can be used in places where \TeX requires a number and for example

within a low-level `\edef` operation to give a purely numerical result. As a brief overview, the floating-point expressions may comprise:

- Basic arithmetic: addition $x + y$, subtraction $x - y$, multiplication $x * y$, division x / y , square root \sqrt{x} , and parentheses.
- Comparison operators: $x < y$, $x \leq y$, $x > y$, $x \neq y$, etc.
- Boolean logic: sign `sign` x , negation `!` x , conjunction $x \&\& y$, disjunction $x || y$, ternary operator $x ? y : z$.
- Exponentials: `exp` x , `ln` x , x^y .
- Integer factorial: `fact` x .
- Trigonometry: `sin` x , `cos` x , `tan` x , `cot` x , `sec` x , `csc` x expecting their arguments in radians, and `sind` x , `cosd` x , `tand` x , `cotd` x , `secd` x , `cscd` x expecting their arguments in degrees.
- Inverse trigonometric functions: `asin` x , `acos` x , `atan` x , `acot` x , `asec` x , `acsc` x giving a result in radians, and `asind` x , `acosd` x , `atand` x , `acotd` x , `asecd` x , `acscd` x giving a result in degrees.
- Extrema: `max`(x_1, x_2, \dots), `min`(x_1, x_2, \dots), `abs`(x).
- Rounding functions, controlled by two optional values, n (number of places, 0 by default) and t (behavior on a tie, NaN by default):
 - `trunc`(x, n) rounds towards zero,
 - `floor`(x, n) rounds towards $-\infty$,
 - `ceil`(x, n) rounds towards $+\infty$,
 - `round`(x, n, t) rounds to the closest value, with ties rounded to an even value by default, towards zero if $t = 0$, towards $+\infty$ if $t > 0$ and towards $-\infty$ if $t < 0$.
- Random numbers: `rand`() , `randint`(m, n).
- Constants: `pi`, `deg` (one degree in radians).
- Dimensions, automatically expressed in points; e.g., `pc` is 12.
- Automatic conversion (no need for `\number`) of integer, dimension, and skip variables to floating-point numbers, expressing dimensions in points and ignoring the stretch and shrink components of skips.
- Tuples: (x_1, \dots, x_n) that can be added together, multiplied or divided by a floating point number, and nested.

The next example shows a computation with input on the left as a formula and output on the right (in blue) and a random number generation and a few dice rolls, so the result of that part will vary each time you rerun the example.

<p>LaTeX can now compute:</p> $\frac{\sin(3.5)}{2} + 2 \cdot 10^{-3} = -0.1733916138448099$	<pre> \usepackage{color} \newcommand\dice{\fpeval{randint(1,6)}} \LaTeX{} can now compute: \[\frac{\sin (3.5)}{2} + 2\cdot 10^{-3} = \mathcolor{blue}{\fpeval{sin(3.5)/2 + 2e-3}} \]</pre>
<p>A random number: 0.1815724000112577 and six dice rolls: 6,1,2,1,6,4.</p>	<p>A random number: $\fpeval{rand()}$ and six dice rolls: $\dice, \dice, \dice, \dice, \dice, \dice$.</p>

$\text{\inteval}\{integer\ expression\}$

The expandable command `\inteval` takes as its argument an integer expression and produces a result using the normal rules of mathematics with some restrictions, as explained below. The operations recognized are +, −, *, and / plus parentheses. As this command is expandable, it can be used when TeX requires a number and, for example, within a low-level `\edef` operation to give a purely numerical result.

This is basically a thin wrapper for the primitive `\numexpr` command and therefore has some syntax restrictions. These are:

- / denotes division rounded to the closest integer with ties rounded away from zero;
- there is an error, and the overall expression evaluates to zero whenever the absolute value of any intermediate result exceeds $2^{31} - 1$, except in the case of scaling operations $a*b/c$, for which $a*b$ may be arbitrarily large;
- parentheses may not appear after unary + or −; namely, placing +(or −(at the start of an expression or after +, −, *, /, or (*expr*) leads to an error.

In the example we calculate $1 < \frac{5}{3} < 2$ in different ways, which according the above rules is always rounded to 2. Note the need to add 0 in the last part of the equation to avoid an unary minus in front of the open parenthesis (which would fail because of the above restriction). For comparison we also do the calculation with `\fpeval`, which shows that the floating-point calculation does not have this issue (but of course it is much slower as it is fully programmed in TeX macros).

<p>$2 = 2 = 2$</p>	<pre> \[\inteval{5/3} = \inteval{-5/-3} = \inteval{0 - (5/-3)} \] \[\fpeval{floor(5/3)} \leq \fpeval{ceil(-5/-3)} \approx \fpeval{-(5/-3)} \]</pre>
<p>A-2-12 $1 \leq 2 \approx 1.6666666666666667$</p>	

<code>\dimeval{<i>dimen expression</i>}</code>	<code>\skipeval{<i>skip expression</i>}</code>
--	--

Similar to `\interval` but computing a length (*dimen*) or a rubber length (*skip*) value. Both are thin wrappers around the corresponding engine primitives, which makes them fast but therefore shows the same syntax peculiarities as discussed above. Nevertheless, in practice they are usually sufficient. For example,

```
\newcommand\calculateheight[1]{%
  \setlength\textheight{\dimeval{\topskip+\baselineskip*\interval{#1-1}}}}
```

sets the `\textheight` to the appropriate value if a page should hold a specific number of text lines. Thus, after `\calculateheight{40}`, it is set to 467.08005pt, given the values `\topskip` (10.0pt) and `\baselineskip` (11.72pt) in this book.

Use `\dimeval` if you are interested in a rigid length as a result, and use `\skipeval` if the calculation involves rubber lengths and the result should also be expressed with plus and minus components; e.g., above both `\topskip` and `\baselineskip` are rubber lengths (i.e., can have plus and minus parts), but we want to calculate the necessary `\textheight`, which is a rigid length, so `\dimeval` was used.

A.3 Page markup — Boxes and rules

The theory of composing pages out of boxes lies at the very heart of T_EX, and several L^AT_EX constructs are available to take advantage of this method of composition. A *box* is a rectangular object with a height, depth, and width. Its contents can be arbitrarily complex, involving other boxes, characters, spaces, and so forth. Once built it is used by L^AT_EX as a single, fixed object that behaves much like a (potentially huge) character. A box cannot be split and broken across lines or pages. Boxes can be moved up, down, left, and right. L^AT_EX has three types of boxes:

LR (left-right) The contents of this box are typeset from left to right. Line breaking is impossible, and commands like `\` and `\newline` are ignored or produce error messages.

Par (paragraphs) This kind of box can contain several lines, which are typeset in paragraph mode just like normal text. Paragraphs are put one on top of the other. Their widths are controlled by a user-specified value.

Rule A (thin or thick) line that is often used to separate various logical elements on the output page, such as table rows and columns, and running titles and the main text.

L^AT_EX's boxes all start a paragraph (just like characters) if used in vertical mode, while T_EX's primitive box commands (e.g., `\hbox`) behave differently depending on where they are used. There are a number of reasons to avoid using the T_EX primitives directly; see the discussion in Section A.3.5. The situation with rules is slightly different; we therefore discuss T_EX's primitive rule commands below.

A.3.1 LR boxes

In this section we look at horizontally oriented boxes with and without a frame.

<code>\mbox{<i>text</i>}</code>	<code>\fbox{<i>text</i>}</code>
<code>\makebox[<i>width</i>][<i>pos</i>]{<i>text</i>}</code>	<code>\framebox[<i>width</i>][<i>pos</i>]{<i>text</i>}</code>

The first line considers the *text* inside the curly braces as a box, without or with a frame drawn around it. For example, `\fbox{some words}` gives some words. The two commands on the second line are a generalization of these commands. They allow the user to specify the width of the box and the positioning of the text inside.

A-3-1	<div style="display: inline-block; border: 1px solid black; padding: 5px 20px;">some words</div>	<pre>\makebox[5cm]{some words} \par \framebox[5cm][r]{some words}</pre>
-------	--	--

In addition to centering the text with the positional argument `[c]` (the default), you can position the text flush left (`[l]`) or flush right (`[r]`). There is also an `[s]` specifier that stretches your *text* from the left margin to the right margin of the box provided it contains some stretchable space (e.g., some `\hspace` or the predefined spaces given in Table A.2 on page 653). Interword spaces are also stretchable (and shrinkable to a certain extent), as explained on page →I 745. The appearance of frameboxes can be controlled by two style parameters:

`\fboxrule` The width of the lines for the box produced with the command `\fbox` or `\framebox`. The default value in all standard classes is 0.4pt.

`\fboxsep` The space left between the edge of the box and its contents by `\fbox` or `\framebox`. The default value in all standard classes is 3pt.

Any changes to these parameters obey the normal scoping rules and affect all frameboxes within the scope. The change to `\fboxsep` in the next example, for instance, applies only to the second box.

A-3-2	<div style="display: inline-block; border: 1px solid black; padding: 5px 20px;">Boxed Text</div> <div style="display: inline-block; border: 2px solid black; padding: 5px 20px; margin-left: 10px;">Boxed Text</div> <div style="display: inline-block; border: 3px solid black; padding: 5px 20px; margin-left: 10px;">Boxed Text</div>	<pre>\fbox{Boxed Text} \hfill \setlength\fboxrule{2pt}% {\setlength\fboxsep{2mm}\fbox{Boxed Text}} \hfill \fbox{Boxed Text}</pre>
-------	--	---

The box commands with arguments for specifying the dimensions of the box allow you to make use of four special length parameters: `\width`, `\height`, `\depth`, and `\totalheight`. They specify the natural size of the *text*, where `\totalheight` is the sum of `\height` and `\depth`.

A-3-3	<div style="display: inline-block; border: 1px solid black; padding: 5px 20px;">A few words of advice</div> <div style="display: inline-block; border: 1px solid black; padding: 5px 20px; margin-left: 10px;">A few words of advice</div> <div style="display: inline-block; border: 1px solid black; padding: 5px 20px; margin-left: 10px;">A few words of advice</div>	<pre>\usepackage{calc} \framebox{ A few words of advice } \par \framebox[\width + 8mm][s]{ A few words of advice } \par \framebox[1.5\width]{ A few words of advice }</pre>
-------	---	--

Zero-width boxes are very handy if you want to put a marker on the page (e.g., for placement of figures) or to allow text to be put into the margins. The principle of operation is shown below, where a zero-width box is used to tag text, without influencing the centering. Note that the optional parameter [1] ([r]) makes the material stick out to the right (left).

A sentence. ¹²³	<code>\centering</code>	
Some more text in the middle.	<code>A sentence.\makebox[0pt][l]{123}\%</code>	
³²¹ A sentence.	<code>Some more text in the middle. \%</code>	
	<code>\makebox[0cm][r]{321}A sentence.</code>	A-3-4

⇔ As seen in the margin of the current line, boxes with a vanishing width can be used to make text stick out into the margin. This effect was produced by beginning the current paragraph in the following way:

```
\noindent\makebox[0cm][r]{\Leftrightarrow}%
As seen in the margin ...
```

Useful,
but dangerous

There are also three useful but somewhat dangerous lower-level commands you often find in package code: `\llap`, `\clap`, and `\rlap`. Each of them takes one mandatory argument, the material to be placed. They are implemented as simple zero-sized `\hboxes` whose contents stick out to the left, are centered, or to the right, respectively.

They inherit the behavior of the `\hbox` command; i.e., they do not start a paragraph if used in vertical mode (which is sometimes what you want), but more importantly they are not color safe unless you add an extra pair of braces in their argument.

An interesting possibility is to raise or lower boxes. This can be achieved by the very powerful `\raisebox` command, which has two mandatory arguments and two optional arguments:

`\raisebox{lift}[height][depth]{contents}`

To raise or lower the box produced from the *contents*, one specifies the amount of *lift* as a dimension, with negative values lowering the box. As with other boxes, one can make use of the special commands `\height`, `\depth`, `\totalheight`, or even `\width` to refer to the natural dimensions of the box produced from *contents*. This is used in the next example to raise the word “upward” so that the descender of the “p” aligns with the baseline and to lower the word “downward” so that it is placed completely below the baseline.

x111x upward x222x	x333x	x111x \raisebox{\depth}{upward} x222x	x333x
downward		\raisebox{-\height}{downward}	

A-3-5

Normally, L^AT_EX takes the added height and depth into account when calculating the distance between the lines so that a raised or lowered box can result in spreading lines apart. This can be manipulated by specifying a *height* and a *depth* that the user

wants \LaTeX to actually use when placing its material on the page. The second pair of lines below shows that \LaTeX does not realize that text has been moved upward and downward; thus, it composes the lines as though all the text was on the baseline.

A-3-6

<pre>x111x downward x222x x333x upward x444x</pre>	<pre>\begin{flushleft} x111x \raisebox{-1ex}{downward} x222x \\ x333x \raisebox{1ex}{upward} x444x \\[4mm] x111x \raisebox{-1ex}[0cm][0cm]{downward} x222x\\ x333x \raisebox{1ex}[0cm]{upward} x444x \end{flushleft}</pre>
---	--

A somewhat more useful application is discussed in Section 6.7 on page 476, which addresses the subject of columns spanning multiple rows in `tabular` material.

A.3.2 Paragraph boxes

Paragraph boxes are constructed using the `\parbox` command or `minipage` environment. The *text* material is typeset in paragraph mode inside a box of width *width*. The vertical positioning of the box with respect to the text baseline is controlled by the one-letter optional parameter *pos* (`[c]`, `[t]`, or `[b]`).

<pre>\parbox[<i>pos</i>]{<i>width</i>}{<i>text</i>}</pre>	<pre>\begin{minipage}[<i>pos</i>]{<i>width</i>} <i>text</i> \end{minipage}</pre>
---	--

The center position is the default, as shown in the next example. Note that \LaTeX might produce wide interword spaces if justification is requested (default) and the measure is incredibly small.

A-3-7

<pre>This is the con- tents of the left- most parbox.</pre>	<pre> This is the right- most parbox. Note that the typeset text looks sloppy be- cause \LaTeX cannot nicely balance the material in these narrow columns.</pre>	<pre>\parbox{.3\linewidth}{This is the contents of the left-most parbox.} \hfill CURRENT LINE \hfill \parbox{.3\linewidth}{This is the right-most parbox. Note that the typeset text looks sloppy because \LaTeX{} cannot nicely balance the material in these narrow columns.}</pre>
---	--	---

The `minipage` environment is very useful for the placement of material on the page. In effect, it is a complete miniversion of a page and can contain its own footnotes, paragraphs, and `array`, `tabular`, `multicols`, and other environments. Note, however, that it cannot contain floats or `\marginpar` commands, but it can appear inside `figure` or `table` environments, where it is often used for constructing a pleasing layout of the material inside the float. A simple example of a `minipage`

```
\newcommand\HR{\rule{.5em}{0.4pt}}
\HR\begin{minipage}[b]{12mm}
    A A A A A A A A A A A A A A
\end{minipage}\HR
\begin{minipage}[c]{12mm}
    B B B B B B B B B B B B B B B B B B B B B B B B
\end{minipage}\HR
\begin{minipage}[t]{12mm}
    C C C C C C
\end{minipage}\HR
```

	<code>\newcommand\HR{\rule{.5em}{0.4pt}}</code>
	<code>\HR\begin{minipage}[b]{30mm}</code>
<code>CCCC</code>	<code>\begin{minipage}[t]{12mm}</code>
<code>AAAA xx BBBB CCC</code>	<code>AAAA AAAA AAAA AAAA AAAA</code>
<code>AAAA BBBB</code>	<code>\end{minipage} xx \begin{minipage}[t]{12mm}</code>
<code>AAAA BBBB</code>	<code>BBBB BBBB BBBB BBBB BBBB BBBB BBBB</code>
<code>AAA BBBB</code>	<code>\end{minipage}</code>
<code>BBBB</code>	<code>\end{minipage}\HR</code>
<code>BBBB</code>	<code>\begin{minipage}[b]{12mm} CCCC CCCC \end{minipage}\HR</code>

		<code>\newcommand\HR{\rule{.5em}{0.4pt}}</code>
		<code>\HR\begin{minipage}[b]{30mm}</code>
		<code>\begin{minipage}[t]{12mm}</code>
		<code>A A A A A A A A A A A A A A</code>
A A A A xx B B B B		<code>\end{minipage} xx \begin{minipage}[t]{12mm}</code>
A A A A B B B B		<code>B B</code>
A A A A B B B B		<code>\end{minipage}</code>
A A A B B B B		<code>\par\vspace{0mm} % modification to previous example</code>
B B B B C C C C		<code>\end{minipage}\HR</code>
— B B B B _ C C C —		<code>\begin{minipage}[b]{12mm} C C C C C C C \end{minipage}\HR</code>

664

In the case below, the two rightmost environments are aligned at their top inside another enclosing environment, which is aligned at its bottom with the first one. If you compare it with the previous example, then you see that you obtain a quite different result, although the sequence of alignment parameters is the same. Only the stacking order of the minipage environments is different.

A-3-11

```

\newcommand\HR{\rule{.5em}{0.4pt}}
\HR\begin{minipage}[b]{12mm}
  A A A A A A A A A A A A A A \end{minipage}\HR
\begin{minipage}[b]{30mm}
  \begin{minipage}[t]{12mm}
    B B B B xx C C C C
    B B B B   C C C
    A A A A B B B B
    A A A A B B B B
    A A A A B B B B
    _A A A _B B B B
  \end{minipage} xx
  \begin{minipage}[t]{12mm} C C C C C C C \end{minipage}
  \par\vspace{0mm}
\end{minipage}\HR

```

Again, we had to add some vertical space to achieve alignment. This does not, however, always produce the desired result. If, for instance, a letter with a descender appears in the last line of the stacked minipage, as in the example below, then the alignment of the baselines is not perfect.

A-3-12

```

\newcommand\HR{\rule{.5em}{0.4pt}}
\HR\begin{minipage}[b]{12mm}
  A A A A A A A A A A A A A A \end{minipage}\HR
\begin{minipage}[b]{30mm}
  \begin{minipage}[t]{12mm}
    B B B B xx C C C C
    B B B B   C C C
    B B B B
    A A A A B B B B
    A A A A B B B B
    A A A A B B B B
    _A A A _gg jj
  \end{minipage} xx
  \begin{minipage}[t]{12mm} C C C C C C C \end{minipage}
  \par\vspace{0mm}
\end{minipage}\HR

```

To correct this problem, you have to add (negative) vertical space that compensates for the depth of the letters.

Perhaps the easiest way (albeit the most dangerous) is to use the TeX primitive `\prevdepth`. This dimension register can be used only in vertical mode (i.e., after a paragraph has ended) and contains the depth of the previous line. In the next example this primitive is used to back up by this amount, thereby pretending that the bottom of the box is located at the baseline of the last line.

When using `\prevdepth` in this way, one has to be careful. As already mentioned, it gives an error if used outside vertical mode. Furthermore, TeX overloads this primitive by setting it to -1000pt at the beginning of a vertical box and after a horizontal rule.¹ Thus, using `\vspace*` instead of `\vspace` in the example would give a nasty surprise, because

 Surprising effects
of `\prevdepth`

¹TeX uses `\prevdepth` to calculate the interline space needed, and -1000pt indicates that this space should be suppressed.

	<code>\newcommand\HR{\rule{.5em}{0.4pt}}</code>
	<code>\HR\begin{minipage}[b]{12mm}</code>
	<code> A A A A A A A A A A A A A A \end{minipage}\HR</code>
<code> B B B B xx C C C C</code>	<code>\begin{minipage}[b]{30mm}</code>
<code> B B B B C C C</code>	<code> \begin{minipage}[t]{12mm}</code>
<code> B B B B</code>	<code> B B B B B B B B B B B B B B B B B B B gg jj</code>
	<code> \par\vspace{-\prevdepth}</code>
<code> A A A A B B B B</code>	<code> \end{minipage} xx</code>
<code> A A A A B B B B</code>	<code> \begin{minipage}[t]{12mm} C C C C C C C \end{minipage}</code>
<code> A A A A B B B B</code>	<code> \par\vspace{0pt}</code>
<code> _A A A _gg jj</code>	<code> - \end{minipage}\HR</code>

```
\parbox[pos][height][inner-pos]{width}{text}
\begin{minipage}[pos][height][inner-pos]{width}
text
\end{minipage}
```

As with the other box commands you can use `\height`, `\totalheight`, and so on to refer to the natural dimensions of the box when specifying the optional argument.

Some text on top.	This time a few lines on the top of the box. But only one line
And a few lines on the bottom of the box.	down here.

A.3.3 Rule boxes

TeX's rule boxes are drawn with the `\rule` command:

```
\rule[lift]{width}{height}
```

If we write `\rule[4pt]{2cm}{1mm}`, then we get a 2 cm long rule that is 1 mm thick and raised 4 pt above the baseline: . The `\rule` command can also be used to construct rule boxes with zero width, that is, invisible rules (also called *struts*). These struts are useful if you need to control the height or width of a given box (for example, to increase the height of a box framed with `\fbox` or `\framebox` or to adjust locally the distance between rows in a table). Compare the following:

x111x	<div style="border: 1px solid black; padding: 2px 10px;">some text</div>	x222x	<div style="border: 1px solid black; width: 80px; height: 80px; display: flex; align-items: center; justify-content: center;">more text</div>	x333x	<pre>x111x \fbox{some text} x222x \fbox{\rule[-5mm]{0cm}{15mm}more text} x333x</pre>
-------	--	-------	---	-------	--

A-3-15

As mentioned earlier, TeX makes boxes (including rules) behave like characters. For example, if used outside a paragraph, they automatically start a new paragraph. With rules this is not always the desired behavior. To get a rule between two paragraphs, for instance, we have to use `\noindent` to suppress a paragraph indentation; otherwise, the line would be indented and stick out to the right.

... Some text for our page that might get reused over and over again.

```
\newcommand\sample{ Some text for our page
that might get reused over and over again.}
\ldots \sample \par
\noindent\rule{\linewidth}{0.4pt} \par
A following paragraph. \sample
```

A following paragraph. Some text for our page that might get reused over and over again.

A-3-16

Due to this behavior, the rule sits on the baseline of a one-line paragraph and is therefore visually much closer to the following paragraph. To place it at equal distance between the two lines, one could use the optional *lift* argument, but determining the right value (roughly 2.5 pt in this particular case) remains a matter of trial and error.

One solution is to suppress the generation of interline space, using the low-level TeX command `\nointerlineskip`, and to add the necessary spaces explicitly as shown in the next example. This time we omit `\noindent` so that the rule is indented by `\parindent`, and we use `calc` to calculate the rule width such that it leaves a space of size `\parindent` on the right as well.

... Some text for our page that might get reused over and over again.

```
\usepackage{calc} % \sample as before
\ldots \sample \par
\nointerlineskip \vspace{5.8pt}
\rule{\linewidth-2\parindent}{0.4pt}\par
\nointerlineskip \vspace{5.8pt}
A following paragraph. \sample
```

A following paragraph. Some text for our page that might get reused over and over again.

A-3-17

	width	height	depth
<code>\hrule</code>	*	0.4pt	0.0pt
<code>\vrule</code>	0.4pt	*	*

Table A.4: Default values for T_EX's rule primitives

The sum of the vertical spaces used plus the height of the rule amounts to 12 points (i.e., `\baselineskip`). However, this does not make the baselines of the two paragraphs 12 points apart; rather, it makes the distance from the bottom of the last line in the first paragraph (i.e., as produced by the “g” in “again”) to the top of the first line in the next paragraph (i.e., as produced by the “A”) be 12 points. Thus, if the text baselines should preferably fall onto a grid, a variant of Example A-3-16 on the previous page using the optional *lift* argument is more appropriate.

Instead of using `\rule` together with `\nointerlineskip`, package or class writers often use the primitive T_EX rule commands. They have the advantage of automatically suppressing interline space and do not require you to specify all dimensions. On the downside, they have an unusual syntax and cannot be used if the rule needs horizontal or vertical shifting, as in the previous example.

```
\hrule height height depth depth width width \relax
\vrule height height depth depth width width \relax
```

The `\hrule` primitive can be used only between paragraphs, while the `\vrule` primitive has to appear within paragraphs. If encountered in the wrong place, the commands stop or start a paragraph as necessary. The commands can be followed by one or more of the keywords `height`, `depth`, and `width` together with a dimension value. Any order is allowed, and missing keywords get the defaults shown in Table A.4. An asterisk in that table means that the rule extends to the boundary of the outer box. The `\relax` command at the end is not required but ensures that T_EX knows that the rule specification has ended and does not misinterpret words in the text as keywords.

In the next example we use the default value for `\hrule`, resulting in a rule of 0.4pt height running through the whole galley width (because this is effectively the next outer box).

```

... Some text for our page that might get reused
over and over again.

A following paragraph. | Some text for our page
that might get reused over and over again.

% \sample as before
\ldots \sample

\vspace{6pt}\hrule\relax\vspace{6pt}
A following paragraph.
\vrule height 12pt width 2pt\relax \
\sample
```

A-3-18

If you are interested in dashed rules, take a look at the `dashrule` package by Scott Pakin, which implements an `\hdashrule` command that can be used in place of

`\rule`. The first optional argument specifies the vertical placement, and the second handles the alignment of the dashes: by default the dashes are always in the same position on different lines, `c` centers the dash pattern in the available space, and `x` expands the pattern to fill the available space; i.e., it usually alters the spaces between the dashes. For more details see the package documentation.

A.3.4 Manipulating boxed material

Material can be typeset once and then stored inside a named box, whose contents can later be retrieved.

<code>\newsavebox{cmd}</code>	Declare box
<code>\sbox{cmd}{text}</code>	Fill box
<code>\savebox{cmd}[width][pos]{text}</code>	Fill box
<code>\usebox{cmd}</code>	Use contents

The command `\newsavebox` globally declares a command `cmd` (for example, `\mybox`), which can be thought of as a named bin. Typeset material can be stored there for later (multiple) retrieval.

The `\sbox` and `\savebox` commands are similar to `\mbox` and `\makebox`, except that they save the constructed box in the named bin (previously allocated with `\newsavebox`) instead of directly typesetting it. The `\usebox` command then allows the nondestructive use of the material stored inside such named bins. You can reuse the same bin (e.g., `\mybox`) several times within the scope of the current environment or brace group. It always contains what was last stored in it.

A-3-20

	<code>\newsavebox{\myboxa}\newsavebox{\myboxb}</code>
	<code>\sbox{\myboxa}{inside box a}</code>
	<code>\savebox{\myboxb}[2cm][l]{inside box b}</code>
	<code>x1x \usebox{\myboxa} x2x \usebox{\myboxb} x3x</code>
	<code>\savebox{\myboxb}[2cm][r]{inside box b}</code>
	<code>\par</code>
<code>x1x inside box a x2x inside box b x3x</code>	<code>x1x \usebox{\myboxa} x2x \usebox{\myboxb} x3x</code>
<code>x1x inside box a x2x inside box b x3x</code>	

Be careful not to use the command name `\mybox` directly, because it contains only the \TeX register number of the box in question. As a consequence, `\mybox` on its

own merely typesets the character at the position corresponding to the box number in the current font. Thus, you should manipulate boxes exclusively using the commands described above.

In addition to the above commands, there exists the `lrbox` environment with the following syntax:

```
\begin{lrbox}{cmd}
  text
\end{lrbox}
```

Here *cmd* should be a box register previously allocated with `\newsavebox`. The environment `lrbox` saves the *text* in this box for later use with `\usebox`. Leading and trailing spaces are ignored. Thus, `lrbox` is basically the environment form of `sbox`. You can make good use of this environment if you want to save the body of some environment in a box for further processing. For example, the following code defines the environment `fcolumn`, which works like a column-wide `minipage` but surrounds its body with a frame.

```
\usepackage{calc}
\newsavebox{\fcolbox} \newlength{\fcolwidth}
\newenvironment{fcolumn}[1][\linewidth]
  {\setlength{\fcolwidth}{#1-2\fboxsep-2\fboxrule}%
   \begin{lrbox}{\fcolbox}\begin{minipage}{\fcolwidth}}
  {\end{minipage}\end{lrbox}\noindent\fbbox{\usebox{\fcolbox}}}
\begin{fcolumn} In this environment verbatim text like
\verb=\fcolbox= can be used. \end{fcolumn}
```

In this environment verbatim text like `\fcolbox` can be used.

A-3-21

The above definition is interesting in several respects. The environment is defined with one optional argument denoting the width of the resulting box (default `\linewidth`). On the next line we calculate (using the `calc` package) the internal line length that we have to pass to the `minipage` environment. Here we have to subtract the extra space added by the `\fbox` command on both sides. Then the `lrbox` and `minipage` environments are started to typeset the body of the `fcolumn` environment into the box `\fcolbox`. When the end of the environment is reached, those environments are closed. Then the `\fcolbox` is typeset inside an `\fbbox` command. The `\noindent` in front suppresses any indentation in case the environment is used at the beginning of a paragraph or forms a paragraph by itself.

A.3.5 Box commands and color

Even if you do not intend to use color in your own documents, by taking note of the points in this section you can ensure that your class or package is compatible with the `color` package. This may benefit people who choose to use your class or package together with the `color` package extensions.

The simplest way to ensure “color safety” is to always use L^AT_EX box commands rather than T_EX primitives — that is, to use `\sbox` rather than `\setbox`, `\mbox`

rather than `\hbox`, and `\parbox` or the `minipage` environment rather than `\vbox`. The L^AT_EX box commands have new options that make them as powerful as the T_EX primitives.

As an example of what can go wrong, consider that in `{\ttfamily text}` the font is restored just *before* the `}`, whereas in the similar-looking construct `{\color{green} text}` the color is restored just *after* the final `}`. Normally, this distinction does not matter. But consider a primitive T_EX box assignment such as

```
\setbox0=\hbox{\color{green} some text}
```

Now the color-restore operation occurs after the `}` and so is *not* stored in the box. Exactly which bad effects this introduces depends on how color is implemented: the problems can range from getting the wrong colors in the rest of the document to causing errors in the Device Independent File Format (DVI) driver used to print the document.

Also of interest is the command `\normalcolor`. This is normally just `\relax` (i.e., does nothing), but you can use it like `\normalfont` to set regions of the page, such as captions or section headings, to the “main document color”.

A.4 L^AT_EX's hook management

Hooks are places in the code where packages can add code, for example, to do some initialization or to execute some final cleanup. In the past L^AT_EX offered just a few heavily used hooks, e.g., `\AtBeginDocument`. Every other alteration or addition made by a package was done by overwriting existing kernel code, leading to all kinds of known issues. Furthermore, these hooks simply stored code added to them in the order it was added to the hook, which resulted in conflicts if packages were loaded in the wrong order.

Therefore, in 2020, a new hook management system and a larger number of hooks were added to L^AT_EX, into which packages can add code in a controlled manner, avoiding the need for patching commands. The new system provides standard interfaces for declaring and using hooks, including ways to order code added to hooks by different packages in order to resolve package loading problems, and plenty more.

A.4.1 Working with existing hooks

We first discuss how you use existing hooks. Later sections then deal with adding new hooks to your own code. To add code to a hook defined by a package or by the L^AT_EX kernel (or remove code from it) you use one of the declarations discussed below. One of the important aspects of this process is that you can do that even before the hook is officially made available. This allows you to add code to hooks defined in a package even if that package is not yet loaded. If this hook never gets defined (because the package is not loaded), then your code is dropped at `\begin{document}`. This solves some of the issues that made loading order of packages in the past so fragile.

*Adding code to
hooks*

<code>\AddToHook{hook}[label]{code}</code> <code>\RemoveFromHook{hook}[label]</code>
--

To add code to a hook you call `\AddToHook` with the name of the *hook* as the first mandatory argument and the *code* to add to the hook as the second. The optional *label* is normally not needed; but it can be used to identify the *code* within the *hook*. By default, this *label* is automatically determined to be the package or class name if used in a package or class or the special string `top-level` if used in the preamble or the body of the document.¹

If several calls to `\AddToHook` use the same *label* (and the same *hook* name), their code is combined and becomes a single chunk of “labeled” code.

Code added this way to hooks is executed whenever the hook is executed, until it is again removed from it. To remove code from an hook you call `\RemoveFromHook` with the *hook* name as a mandatory argument. The default for the optional *label* is determined as described above; i.e., it needs to be given only if you want to remove a specific chunk, which is not the default. You can also use the special notation `*` in the optional argument in which case all code is removed (not recommended unless you know for sure what went into the hook).

Available hooks already provided by L^AT_EX are discussed later. For the next example we just use one without much explanation and add some code to it. The hook `cmd/quote/after` is called at the beginning of the body of `\begin{quote}`; thus, any change we make is local to the environment. To this hook we add code to color the text blue. This is done without specifying a label, so the label used internally is `top-level` because we are in the preamble of the document. In addition, we add another chunk of code to specify `\footnotesize` as the font size. This time we use an explicit label named `quotesize`.²

Later in the document body we call `\RemoveFromHook` without giving a label. Thus, the code removed is the one belonging to the default label, which is `top-level`, and therefore the last quote appears black again. If we would have used the `quotesize` label instead, the quote would have been normal-sized again but still blue, and if we had used `*`, we would have gotten a standard `quote` environment again.

All quotes are in blue:	<code>\usepackage{color}</code>
The Quote.	<code>\AddToHook{cmd/quote/after}{\color{blue}}</code>
	<code>\AddToHook{cmd/quote/after}{quotesize}{\footnotesize}</code>
and in a smaller typeface:	
Another Quote.	<code>\begin{quote} All quotes are in blue: The Quote. \end{quote}</code>
	<code>and in a smaller typeface:</code>
but this one is black:	<code>\begin{quote} Another Quote. \end{quote}</code>
	<code>\RemoveFromHook{cmd/quote/after}</code>
Final Quote!	<code>but this one is black: \begin{quote} Final Quote! \end{quote}</code>

A-4-1

¹Code labeled with `top-level` is special, because it is normally executed last in a hook, which means that code added in the preamble comes after code added by packages; see page 685 for details. This is even the case if the packages are loaded later in the preamble.

²You can think of the `quotesize` chunk being defined in a package with that name. Otherwise, there is little reason to make two separate declarations, unless you really want to partially retract the code you put into the hook as is done in the example.

Please do not mistake this example as the suggested way to alter the behavior of environments such as `quote`. It was just meant to show in a simple example how the commands `\AddToHook` and `\RemoveFromHook` work. The hook we used is one of the generic command hooks (discussed below) that exists for every command. By using it we have made use of knowledge about internal implementation details (namely, that at some point `\begin{quote}` calls `\quote`), which is seldom a good idea.

```
\AddToHookNext{hook}{code}    \ClearHookNext{hook}
```

Sometimes it is useful to execute code only once, i.e., just the next time a hook is called. In theory you could achieve this by including an appropriate `\RemoveFromHook` in the code added with `\AddToHook`, but the hook management offers a more convenient way. The declaration `\AddToHookNext` adds *code* to the *hook* that is executed only once and then automatically removed again. Because this is one-off code, it is not labeled, and it is always added to the end of all hook code so that it can overwrite code in other chunks. Typical use cases for `\AddToHookNext` are the hooks related to shipping out pages; e.g., you may want to use a special background on the next page.

Even though it seems logical that one adds only code for the next invocation of a hook with the intention to see it run, there are some use cases where one may need to cancel that later, and for this `\ClearHookNext` can be used.

Different hook flavors

Hooks can be classified in several ways. Most of them appear in code that can be used multiple times in a document, and each time this happens, the code currently associated with the hook is executed. Such hooks are called “Normal Hooks”, and they make up the majority.

Normal Hooks

Some hooks, however, can be executed only once, for example, any hooks inside `\begin{document}`, because this environment is executed only once. It therefore makes little sense to add new hook code after such hooks have executed or to keep the code associated with the hooks after that point.

One-time Hooks

For these “One-time Hooks”, L^AT_EX applies the following strategy: the *code* in any `\AddToHook` for such a hook that happens during or after the hook is invoked is immediately executed, and not stored away for future invocations. For `\AddToHookNext` this is not done, so if this is used after the one-time hook has executed, it is simply never run.¹ In contrast, adding code with `\AddToHook` during the execution of normal hooks just saves the code away for use in the next invocation, which allows you to build up some chains: do this on the next invocation, do that on the one thereafter, and so forth.

 `\AddToHookNext`
acts in a special
way with one-time
hooks!

Some hooks (whether normal or one-time) come in pairs, for example, the hooks `file/before` and `file/after`, which are executed before and after the loading of every file. Typically the second of such hooks is implemented as a “Reversed Hook”. This means that if you push several code chunks into both hooks, say, labeled A,

Reversed Hooks

¹This gives you a choice: should your *code* always run, or should it run only exactly at the point the one-time hook is executed and, if that is not possible, then not at all?

B, and C and they get executed in one order in the first hook, then the execution order in the reversed hook is exactly the opposite. The reason for this behavior is that it allows you put environments into such hook code chunks, e.g., opening an environment in chunk A of the first hook and closing it in chunk A of the second hook. Without reversing the execution order on the second hook you would get mismatched environments, if environments are added to several chunks. Again, `\AddToHookNext` acts in a special way on reversed hooks, in that it remains being executed at the very end, i.e., does not participate in order reversal. This means that you cannot employ it for the use case outline above, but it gives you the opportunity to “undo” some settings made by other hook chunks just for the next invocation.

`\AddToHookNext`
acts in a special
way with reversed
hooks!

Generic Hooks

There is one further category: some hooks are so called “Generic Hooks”. Normally a hook has to be explicitly declared before it can be used in code. This ensures that different packages are not using the same hook name for unrelated purposes — something that would result in absolute chaos. However, there are a number of “standard” hooks where it is unreasonable to declare them beforehand; e.g., each and every command has (in theory) an associated `before` and `after` hook. In such cases, i.e., for command, environment, or file hooks, they can simply be used by adding code to them with `\AddToHook`. For more specialized generic hooks, e.g., those provided by `babel`, you have to additionally enable them with `\ActivateGenericHook` as explained below.

Displaying current hook status and data

To show data about a hook there are two declarations available. For developers there are also a number of conditionals that let you provide code that acts differently based on the status of a hook. Such conditionals are rather special, and if you need them, consult the hook management documentation [139].

```
\ShowHook{hook}    \LogHook{hook}
```
